public Integer getColSpan(AuthorElement cell) {
  Integer colSpan = null;

  AttrValue attrValue = cell.getAttribute("column_span");
  if(attrValue != null) {
    // The attribute was found.
    String cs = attrValue.getValue();
    if(cs != null) {
      try {
        colSpan = new Integer(cs);
      } catch (NumberFormatException ex) {
        // The attribute value was not a number.
      }
    }
  }
  return colSpan;
}
```

4. The row span is determined in a similar manner:

```
public Integer getRowSpan(AuthorElement cell) {
  Integer rowSpan = null;

  AttrValue attrValue = cell.getAttribute("row_span");
  if(attrValue != null) {
    // The attribute was found.
    String rs = attrValue.getValue();
    if(rs != null) {
      try {
        rowSpan = new Integer(rs);
      } catch (NumberFormatException ex) {
        // The attribute value was not a number.
      }
    }
  }
  return rowSpan;
}
```

5. The method *hasColumnSpecifications* always returns `true` considering column specifications always available.

```
public boolean hasColumnSpecifications(AuthorElement tableElement) {
  return true;
}
```

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

6. In the listing below, the XML document contains the table element:

```
<table>
    <header>
        <td>C1</td>
        <td>C2</td>
        <td>C3</td>
        <td>C4</td>
    </header>
    <tr>
        <td>cs=1, rs=1</td>
        <td column_span="2" row_span="2">cs=2, rs=2</td>
        <td row_span="3">cs=1, rs=3</td>
    </tr>
    <tr>
        <td>cs=1, rs=1</td>
    </tr>
    <tr>
        <td column_span="3">cs=3, rs=1</td>
    </tr>
</table>
```

When no table cell span provider is specified, the table has the following layout:

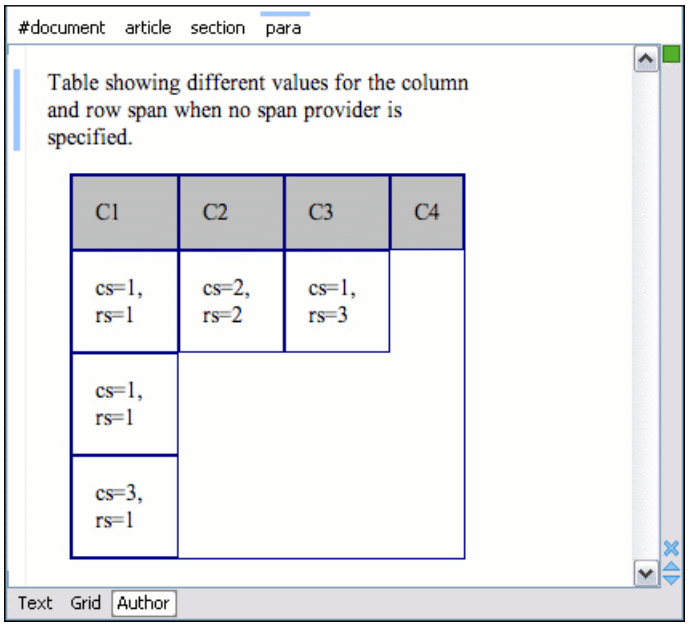

Figure 725: Table layout when no cell span provider is specified

When the above implementation is configured, the table has the correct layout:

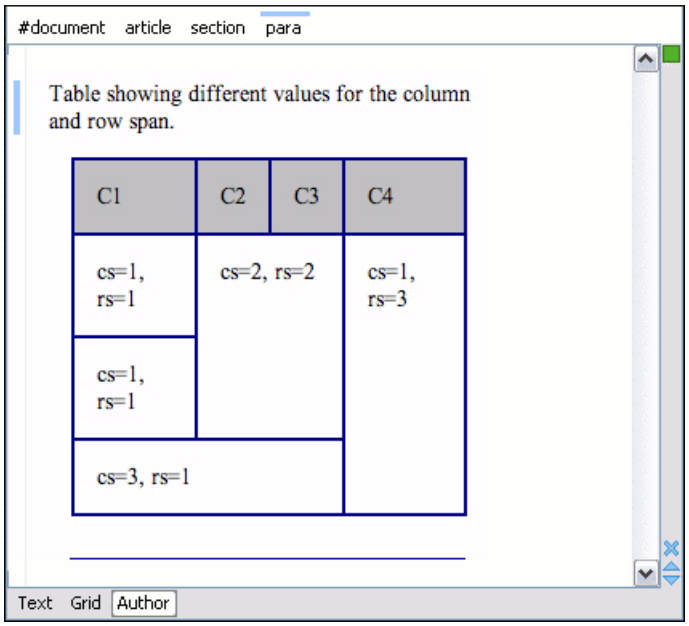

Figure 726: Cells spanning multiple rows and columns.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring a Table Cell Row and Column Separator Provider

In a custom *framework*, the `table` element has separators between rows. As explained in *Configuring Tables* on page 1445, you need to indicate a method to determine the way rows and columns are separated. If you use the `rowsep` and `colsep` cell element attributes, or your table is conforming to the CALS table model, Oxygen XML Editor can determine the cell separators. Even if there are no attributes that define the separators, you can still force a separator between rows by implementing a Java extension.

1. Create the class *simple.documentation.framework.TableCellSepProvider*. This class must implement the *ro.sync.ecss.extensions.api.AuthorTableCellSepProvider* interface.

```
import ro.sync.ecss.extensions.api.AuthorTableCellSepProvider;
import ro.sync.ecss.extensions.api.node.AuthorElement;
```

```
public class TableCellSepProvider implements AuthorTableCellSepProvider{
```

2. The *init* method is taking as argument the *ro.sync.ecss.extensions.api.node.AuthorElement* that represents the XML `table` element. In our case the separator information is implicit, it does not depend on the current table, so you leave this method empty. However, there are cases (such as the CALS table model) when the cell separators are specified in the `table` element. In such cases, you should initialize your provider based on the given argument.

```
public void init(AuthorElement table) {
}
```

3. The *getColSep* method is taking as argument the table cell. The table layout engine will ask this *AuthorTableCellSepProvider* implementation if there is a column separator for each XML element from the table that was marked as cell in the CSS using the property `display:table-cell`. In our case we choose to return **false** since we do not need column separators.

```
  /**
   * @return false - No column separator at the right of the cell.
   */
  @Override
  public boolean getColSep(AuthorElement cellElement, int columnIndex) {
    return false;
  }
```

4. The row separators are determined in a similar manner. This time the method returns **true**, forcing a separator between the rows.

```
  /**
   * @return true - A row separator below each cell.
   */
  @Override
  public boolean getRowSep(AuthorElement cellElement, int columnIndex) {
    return true;
  }
```

   Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

5. In the example below, the XML document contains the table element:

```
<table>
     <header>
       <td>H1</td>
       <td>H2</td>
       <td>H3</td>
       <td>H4</td>
     </header>
     <tr>
       <td>C11</td>
       <td>C12</td>
       <td>C13</td>
       <td>C14</td>
     </tr>
     <tr>
       <td>C21</td>
       <td>C22</td>
       <td>C23</td>
       <td>C24</td>
     </tr>
     <tr>
       <td>C31</td>
       <td>C32</td>
       <td>C33</td>
       <td>C34</td>
     </tr>
   </table>
```

When the borders for the `td` element are removed from the CSS, the row separators become visible:

H1	H2	H3	H4
C11	C12	C13	C14
C21	C22	C23	C24
C31	C32	C33	C34

Figure 727: Row separators provided by the Java implementation.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring a Unique Attributes Recognizer

The *ro.sync.ecss.extensions.api.UniqueAttributesRecognizer* interface can be implemented if you want to provide for your *framework* the following features:

- **Automatic ID generation** - You can automatically generate unique IDs for newly inserted elements. Implementations are already available for the DITA and DocBook *frameworks*. The following methods can be implemented to accomplish this: *assignUniqueIDs(int startOffset, int endOffset)*, *isAutoIDGenerationActive()*
- **Avoiding copying unique attributes when "Split" is called inside an element** - You can split the current *block element* by pressing the "Enter" key and then choosing "Split". This is a very useful way to create new paragraphs, for example. All attributes are by default copied on the new element but if those attributes are IDs you sometimes want to avoid creating validation errors in the editor. Implementing the following method, you can decide whether or not an attribute should be copied during the split: *boolean copyAttributeOnSplit(String attrQName, AuthorElement element)*

  Tip: The *ro.sync.ecss.extensions.commons.id.DefaultUniqueAttributesRecognizer* class is an implementation of the interface that can be extended by your customization to provide easy assignation of IDs in your *framework*. You can also check out the DITA and DocBook implementations of *ro.sync.ecss.extensions.api.UniqueAttributesRecognizer* to see how they were implemented and connected to the extensions bundle.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring an XML Node Renderer Customizer

You can use this API extension to customize the way an XML node is rendered in the ***Outline*** *view* in **Author** mode, *breadcrumb navigation bar* in **Author** mode, ***Outline*** *view* in **Text** mode, *Content Completion Assistant* window, or ***DITA Maps Manager*** *view*.

Note: Oxygen XML Editor uses *XMLNodeRendererCustomizer* implementations for the following *frameworks*: DITA, DITA Map, DocBook 4, DocBook 5, TEI, XHTML, XSLT, and XML Schema.

There are two methods to provide an implementation of *ro.sync.exml.workspace.api.node.customizer.XMLNodeRendererCustomizer*:

- As a part of a bundle, returning it from the *createXMLNodeCustomizer()* method of the *ExtensionsBundle* associated with your document type in the ***Document type*** *configuration dialog box* (**Extensions bundle** field in the **Extensions** tab).
- As an individual extension, associated with your document type in the ***Document type*** *configuration dialog box* (**XML node renderer customizer** field in the **Individual extensions** section of the **Extensions** tab).

Support for Retina/HiDPI Displays

To support Retina or HiDPI displays, the icons provided by the *XMLNodeRendererCustomizer* should be backed up by a copy of larger size using the proper *Retina/HiDPI naming convention*.

For example, for the `title` element, if the *XMLNodeRendererCustomizer* returns the path `${framework}/images/myImg.png`, then to support Retina images with a scaling factor of 2, an extra file (`myImg@2x.png`)should be added to the same images directory (`${framework}/images/myImg@2x.png`). If the higher resolution icon (the *@2x* file) does not exist, the *normal* icon is scaled and used instead.

For more information about using Retina/HiDPI images, refer to the *Using Retina/HiDPI Images in Author Mode* section.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Customizing the Rendering of Elements on page 1464

Adding Custom Persistent Highlights

The *Author API* includes a class that allows you to create or remove custom persistent highlights, set new properties for the highlights, and customize their appearance. An example of a possible use case would be if you want to implement your own way of editing review comments. The custom persistent highlights get serialized in the XML document as processing instructions, with the following format:

```
<?oxy_custom_start prop1="val1"....?> xml content <?oxy_custom_end?>
```

This functionality is available through the *AuthorPersistentHighlighter* class that is accessible through the *AuthorEditorAccess#getPersistentHighlighter()* method.

For more information, see the JavaDoc details for this class at *https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/highlights/AuthorPersistentHighlighter.html*.

Customizing the Main CSS of a Framework

The easiest way to customize the *main* CSS stylesheet of a *framework* is to create a new stylesheet, save it as an *alternate* CSS file that will be applied as an additional layer to the *main* CSS, and then select it from the **Styles** drop-down menu in **Author** mode.

For example, suppose that you want to customize the *main* CSS for DITA documents. To do this, follow these steps:

1. First, create a new CSS stylesheet and save it in the *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/css/edit` folder (where the default *main* stylesheet named `style-basic.css` is located).
2. Edit the DITA *framework* and go to the ***CSS*** *subtab*:
   a) *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to **Document Type Association**.
   b) Select the DITA document type and press the **Edit** button.

   Tip: If you do not have write permissions to modify the document type, use the **Extend** button to create an extension of the *framework*.

   a) Go to the **CSS** subtab of the **Author** tab.

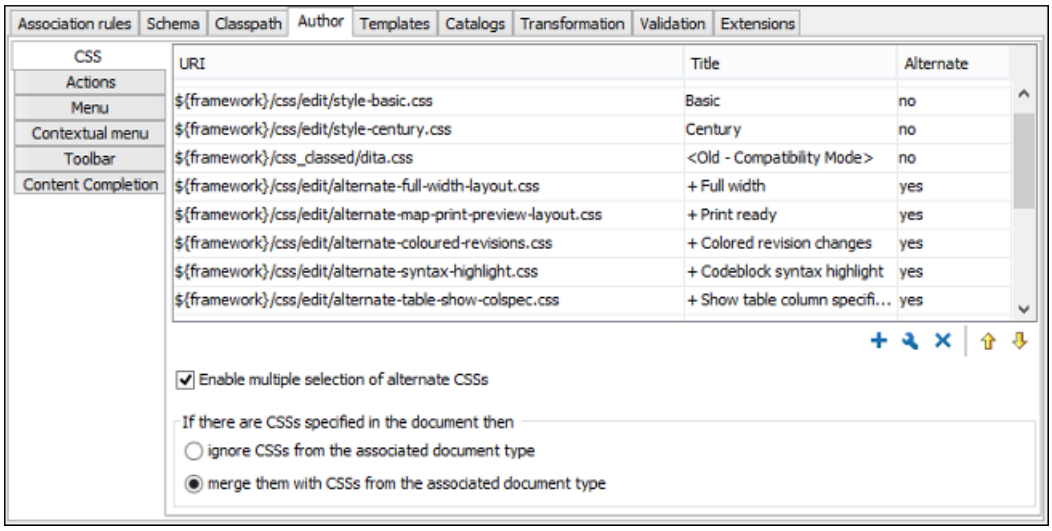

Figure 728: CSS Subtab of the Document Type Association Author Tab

3. Add the new stylesheet as an *alternate* CSS stylesheet:
   a) Click the **Add** button to open a dialog box that allows you to specify the URI and Title for your newly created stylesheet.
   b) Select the **Alternate** option to define it as an *alternate* stylesheet that will applied as an additional layer to the *main* CSS.

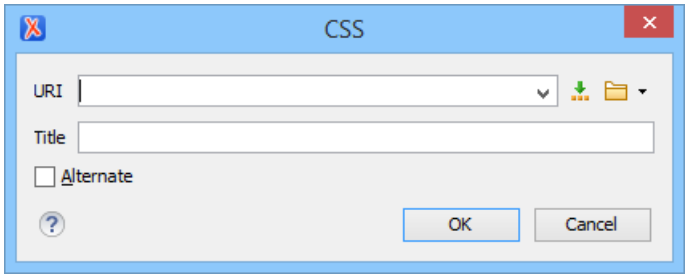

Figure 729: Add CSS Stylesheet Dialog Box

4. Press **OK** in all the dialog boxes to validate the changes.
5. Select your newly created CSS stylesheet from the **Styles** drop-down menu on the toolbar in **Author** mode. You can now edit DITA documents based on the new CSS stylesheet. You can also edit the new CSS stylesheet itself and see its effects on rendering DITA documents in the **Author** mode by using the **Refresh** action that is available on the **Author** toolbar and in the **DITA** menu.

Configuring and Managing Multiple CSS Styles on page 1473

Sharing a Framework (Document Type)

Oxygen XML Editor allows you to share customizations of a specific XML document type by *creating your own framework* in the ***Document Type Association*** *preferences page*.

A *framework* (document type) can be shared with other authors by using any of the following methods:

Save it in a Custom Folder

To share your customized *framework* with other members of your team, you can save it to a separate folder inside the *[OXYGEN_INSTALL_DIR]*`/frameworks` directory by following these steps:

Important: For this approach to work, the application must be installed in a folder with full write access.

1. Go to *[OXYGEN_INSTALL_DIR]*`/frameworks` and create a directory for your new *framework* (for example, `custom_framework`). This directory will contain the resources for your customized *framework*. See the **DocBook** *framework* structure from *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook` as an example.
2. Create your custom document type (*framework*) and specify the `custom_framework` directory for the **External** storage option.
3. Configure the custom document type according to your needs. Take special care to make all file references relative to the *[OXYGEN_INSTALL_DIR]*`/frameworks` directory by using the ***${frameworks}*** *editor variable*. See the *Author Mode Customization* section for more details on creating and configuring a new document type (*framework*).
4. Add any additional resources (CSS files, new file templates, schemas used for validation, catalogs, etc.) to the directory you created in step 1.
5. After completing your customizations in the ***Document Type Association*** *preferences page*, you should have a new configuration file saved in: *[OXYGEN_INSTALL_DIR]*`/frameworks/custom_framework/custom.framework`.
6. To share the new *framework* directory with other users, have them copy it to their *[OXYGEN_INSTALL_DIR]*`/frameworks` directory. The new *framework* will be available in the list of document types when Oxygen XML Editor starts.

   Note: If you have a `frameworks` directory stored on your local drive, you can also go to the ***Document Type Association*** > ***Locations*** *preferences page* and add your `frameworks` directory in the **Additional frameworks directories** list.

Save it at Project Level

You can also share customized *frameworks* by saving it at *project level* in the ***Document Type Association*** *preferences page*. To do so, follow these steps:

1. On your local drive, create a directory with full write access. This directory will contain the resources for your customized *framework* and the project file.
2. Start Oxygen XML Editor, go to the ***Project*** *view* and create a project. Save it in the newly created directory.
3. In the ***Document Type Association*** *preferences page*, select ***Project Options*** at the bottom of the page.
4. Create your custom document type (*framework*) and use the default **Internal** storage option. It will actually be saved in the project file (`.xpr`).
5. Configure the custom document type according to your needs. Take special care to make all file references relative to the project directory by using the ***${pd}*** *editor variable*. See the *Advanced Framework Customization* on page 1385 section for more details on creating and configuring a new document type (*framework*).
6. Add any additional resources (CSS files, new file templates, schemas used for validation, catalogs, etc.) to your project.
7. You can then share the new project directory with other team members. When they open the customized project file in the ***Project*** *view*, the new *framework* becomes available in the list of document types.

Deploy it as an Add-on

You can also share your customized *framework* by deploying it as and add-on. To do so, follow the procedures in *Packing and Deploying Plugins or Frameworks as Add-ons* on page 1421.

Related Information:

Extending and Sharing a Framework (Document Type) on page 1456

Extending and Sharing a Framework (Document Type)

You can extend a predefined, built-in *framework* (document type), such as DITA or DocBook, using the ***Document Type Association*** *preferences page*, make modifications to it, and then share the extension with your team.

Extending a Framework

For the purpose of providing specific instructions for sharing an extended *framework*, suppose that you want to share an extension of the **DITA** *framework* in which you have removed certain elements from the content completion list. The following steps describe how you can create an extended *framework* that can be shared with others:

1. In a location where you have full write access, create a folder structure similar to this: `custom_frameworks/dita-extension`.
2. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to ***Document Type Association > Locations***. In this preferences page, add the path to your `custom_frameworks` folder in the **Additional frameworks directories** list.
3. Go to the ***Document Type Association** preferences page* and select the **DITA** *framework* configuration and use the **Extend** button to create an extension for it.
4. Give the extension an appropriate name (for example, `DITA - Custom`), select **External** for the **Storage** option, and specify an appropriate path (for example, `path/to/.../custom_frameworks/dita-extension/dita-extension.framework`).
5. Make your changes to the extension. For example, you could go to the **Content Completion** subtab of the **Author** tab and in the **Filter - Remove content completion items** list, add elements that you do not want to be presented to the end users.
6. Click **OK** to close the dialog box and then **OK** or **Apply** to save the changes to the ***Document Type Association** preferences page*.

   Results: After you perform these steps you will have a fully functional *framework* in the `dita-extension` folder and it can be shared with others.

Sharing the Extended Framework

There are several ways that you can share the extended *framework* with others:

- Copy it to their *`[OXYGEN_INSTALL_DIR]`*`/frameworks` directory.
- Create a `custom_frameworks` folder (anywhere on disk) and copy the extended *framework* into it. Then add the path to your `custom_frameworks` folder in the **Additional frameworks directories** list in the ***Document Type Association > Locations** preferences page*.
- Distribute the extended *framework* along with a project by following these steps:
  1. On your local drive, create a directory (with full write access) that contains the project files and a `custom_frameworks` folder with your extended *framework* inside.
  2. Start Oxygen XML Editor, go to the ***Project** view* and create a project. Save it in the newly created directory.
  3. In the ***Document Type Association > Locations** preferences page*, select ***Project Options*** at the bottom of the page.
  4. In the **Additional frameworks directories** list, add an entry like this: `${pd}/custom_frameworks`.
  5. Add other resources to your project (for example, you can have all your DITA content located inside the project folder).
  6. You can then share the new project directory with other users. For example, you can commit it to your version control system and have them update their working copy. When they open the customized project file in the ***Project** view*, the new *framework* becomes available in the list of document types.
- Deploy the extended *framework* configuration *as an add-on*.

After your team members install the *framework* they can check the list of document types in the ***Document Type Association** preferences page* to see if the *framework* is present and if it appears before the bundled **DITA** *framework* (meaning that it has higher priority).

Related Information:

Sharing a Framework (Document Type) on page 1455

Customizing the Content Completion Assistant

Oxygen XML Editor gathers information from the associated schemas (DTDs, XML Schema, RelaxNG) to determine the proposals that appear in the *Content Completion Assistant*. Oxygen XML Editor also includes support that allows you to customize the *Content Completion Assistant* to suit your specific needs.

There are two ways to customize the *Content Completion Assistant* in Oxygen XML Editor:

- You can add, modify, or remove actions that are proposed for each particular document type (*framework*) by using the ***Content Completion** subtab in the **Document Type Association** configuration dialog box*. To access this subtab, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Document Type Association**, use the ***New**, **Edit**, **Duplicate**, or **Extend** button*, click on the **Author** tab, and then the **Content Completion** subtab.

- You can use a `cc_config.xml` configuration file that is specific to each document type (*framework*) to configure the values that are proposed in certain contexts, to customize the attributes or elements that are proposed, or to customize how certain aspects of the proposals are rendered in the interface. The rest of the topics in this section explain how you can use this configuration file to customize the content completion.

Configuring the Proposals for Elements and Attributes

There are many cases where elements have a relaxed content model and can accept a large number of child elements. For example, the DITA list item element (`li`) accepts more than 60 child elements. Oxygen XML Editor includes support to allow the content architect to put some constraints on the possible elements or attributes, or to impose some best practices in the way content is edited.

For an example of a specific use-case, suppose that you want to restrict DITA list item elements (`li`) to only accept paragraph elements (p). In this case, the *Content Completion Assistant* should not offer any element other than a paragraph (p) when a list item (`li`) is inserted into a document. It would also be helpful if the required child element (p) was automatically inserted whenever a list item (`li`) is inserted.

One method of changing the content model is to alter the element definition in the associated schema (XML Schema, DTD, RelaxNG), but this may be quite complicated in some cases. Fortunately, Oxygen XML Editor offers a simple, alternative method of using a configuration file to customize the content completion proposals for each element.

Setting up the Content Completion Configuration File

To customize the configuration file for the *Content Completion Assistant*, follow these steps:

1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Document Type Association**. Select the particular document type, click the **Edit** button, and in the ***Classpath** tab* add a link to that `resources` folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.
   a. To easily create a new configuration file, you can use the *Content Completion Configuration* file template that is included in Oxygen XML Editor (**File** > **New** > **Framework templates** > **Oxygen Extensions** > **Content Completion Configuration**). The file template includes details about how each element and attribute is used in the configuration file.
   b. If a configuration file (`cc_config.xml`) already exists for the particular document type (in the `resources` folder), you can modify this existing file.
4. Make the appropriate changes to your custom configuration file.
5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).
6. Restart the application and open an XML document. In the *Content Completion Assistant* you should see your customizations.

   Tip: In some cases, you can simply use the **Refresh (F5)** action to test your customizations, without having to restart the application.

Configuring Elements or Attributes that are Proposed for Each Element

For the purposes of customizing the elements or attributes that are proposed for each individual element, the configuration file (`cc_config.xml`) uses `elementProposals` elements. This element allows you to customize or filter the child elements and attributes for an element.

Warning: Note that you can only choose elements or attributes that are already allowed by the schema in a particular context. For example, you cannot specify an element that is not allowed by the schema as a child of a particular node.

Elements:

To control the **elements** that are proposed for an element, you can use the following attributes for the `elementProposals` element:

- `path` - A path within the document that matches the element that will have its content completion proposals changed. For example, `"title"` matches all the `title` elements in the document, while `"chapter/title"` matches only the `title` elements that are direct children of the `chapter` element. You can use simplified forms of XPath in this attribute.

  The XPath expressions can accept multiple attribute conditions and inside each condition you can use *AND/OR* boolean operators and parentheses to override the priority.

  You can use one or more of the following attribute conditions (default attribute values are not taken into account):

  - *element[@attr]* - Matches all instances of the specified element that include the specified attribute.
  - *element[not(@attr)]* - Matches all instances of the specified element that do not include the specified attribute.
  - *element[@attr = "value"]* - Matches all instances of the specified element that include the specified attribute with the given value.
  - *element[@attr != "value"]* - Matches all instances of the specified element that include the specified attribute and its value is different than the one given.

  Example: The following are examples of how you could use multiple boolean operators and parentheses inside an attribute condition:

  ```
  *[@a and @b or @c and @d]
  *[@a and (@b or @c) and @d]
  ```

  The following are just examples of how simplified XPath expressions might look like:

  - `elementName`
  - `//elementName`
  - `/elementName1/elementName2/elementName3`
  - `//xs:localName`

    Note: Using a namespace prefix requires that you declare it in the configuration file. For example: `<elementProposals xmlns:db5="http://docbook.org/ns/docbook" path="db5:listitem" insertElements="db5:para" />`
  - `//xs:documentation[@lang="en"]`

  Note: If the `path` attribute is missing, the customization will apply to the proposals for all elements. You can intentionally omit this attribute and use *possibleElements* or *rejectElements* to specify or restrict particular elements for a *framework*.

  For example, suppose that in your DITA documents, you want to restrict your users from using `image` and `fig` elements because you do not want images to be included in your output. The configuration file should look like this:

  ```
  <elementProposals rejectElements="image fig" />
  ```

  Since the `path` attribute is missing, the specified element will be filtered out from the proposals for the entire *framework*.
- `insertElements` - A space-separated sequence of child element names. Each time the element specified in the `path` attribute is inserted into the document, these child elements will also be inserted in the order that they are listed. For example, `insertElements="b i"` will insert exactly one b element, followed by an `i` element. An empty value (`""`) means that no child elements should be inserted.

  Note: If this attribute is missing, the default required child elements will be inserted, as specified in the associated schema for the document.
- `possibleElements` - A space-separated list of element names that will be shown in the content completion list when invoked inside an element that is specified in the `path` attribute. For example, `"b i codeph ph"` means that the *Content Completion Assistant* will contain these four elements when invoked on the element specified in the `path` attribute. The following other possible values are also supported:

  - ***NONE*** - There will be no proposals in the content completion list.

- ***ALL*** - All the possible elements specified in the associated schema will be presented in the content completion list. This is also the default behavior if this attribute is missing.
- ***INSERTED*** - The proposals will be the same list of elements that are defined in the `insertElements` attribute.

When using this attribute to specify multiple elements, only use one entry with the element names separated by a space:

```
<elementProposals possibleElements="b i codeph ph" />
```

- `rejectElements` - A space-separated list of element names that will be filtered out from the list of proposals that are presented in the content completion list. Each time the element specified in the `path` attribute is inserted into the document, the list of proposals in the *Content Completion Assistant* will include the entries that are defined in the associated schema, minus the elements specified in this attribute.

  When using this attribute to specify multiple elements, only use one entry with the element names separated by a space:

```
<elementProposals rejectElements="image fig imagemap foreign" />
```

Attributes:

To control the **attributes** that are proposed for an element, you can use the following attributes for the `elementProposals` element:

- `path` - A path within the document that matches the element that will have its attribute proposals changed. For example, `"title"` matches all the `title` elements in the document, while `"chapter/title"` matches only the `title` elements that are direct children of the `chapter` element. You can use simplified forms of XPath in this attribute. For examples of such forms of XPath expressions, see the *note in XML Preferences*.

  Note: If this attribute is missing, the customization will apply to the proposals for all elements. You can intentionally omit this attribute and use *possibleAttributes* or *rejectAttributes* to specify or restrict attributes for an entire *framework*.

  For example, suppose that you only want to allow a limited set of attributes in a customized *framework*. The configuration file should look like this:

```
<elementProposals possibleAttributes="
              id domains href scope format type conref
        props keyref class"/>
```

  Since the `path` attribute is missing, this applies to the entire *framework* and only the specified attributes will be proposed.
- `insertAttributes` - A space-separated sequence of attribute names that will be inserted along with the element.

```
<elementProposals path="ol/li" insertAttributes="product platform"/>
```

- `insertAttribute` - This is similar to the preceding attribute, but this one also allows you to specify a value for the attribute that will be inserted. This attribute should be used like this:

```
<elementProposals path="ol/li">
    <insertAttribute name="platform" value="test"/>
</elementProposals>
```

- `possibleAttributes` - A space-separated list of attribute names that will be shown in the content completion list when invoked inside an element that is specified in the `path` attribute.

  When using this attribute to specify multiple attributes, only use one entry with the attribute names separated by a space:

```
<elementProposals possibleAttributes="scope format type" />
```

- `rejectAttributes` - A space-separated list of attribute names that will be filtered out from the list of proposals that are presented in the content completion list. Each time the element specified in the `path` attribute is inserted into the document, the list of proposals in the *Content Completion Assistant* will include the entries that are defined in the associated schema, minus the attributes specified in this attribute.

When using this attribute to specify multiple attributes, only use one entry with the attribute names separated by a space:

```
<elementProposals rejectAttributes="importance platform product" />
```

Other Important Notes About the Configuration File

Important:

- By default, the element names that do not have a namespace prefix are considered from *no-namespace*. Consider declaring the namespace mapping on the root of the configuration file and prefixing the element names from the `elementPath` and `model` attributes.
- This configuration file only affects the content completion assistance, not validation.
- To test the effects of your changes, you should restart the application, although in some cases, you can simply use the **Refresh (F5)** action to test your customizations.
- When an XML element from the document is matched against a list of configured `elementProposals`, the first one in sequence takes precedence. Therefore, make sure you place the more specific `elementProposals` (those with a longer path) first in your configuration file.
- Regular expression patterns can be used in the following attributes: `possibleElements`, `rejectElements`, `possibleAttributes`, and `rejectAttributes`. For example, `code*`, `*block`, `con*ref`, `_*`.
- Only simple recursion cases are detected and avoided by the editor, and logged to the console. Therefore, if complex `elementProposals` patterns are defined, you should avoid *infinite recursions*.

Examples: Configuring the Element Proposals

- **Example 1: Automatically Insert Elements**

  Suppose that you want to automatically insert a paragraph element (p) whenever a DITA ordered list item element (`ol/li`) is inserted, and also to not allow any other element besides a paragraph inside the ordered list items.

  To achieve this, the configuration file should include the following:

  ```
  <elementProposals path="ol/li" insertElements="p"
        possibleElements="_INSERTED_"/>
  ```

- **Example 2: Insert Complex Element Structure**

  For a more complex example, suppose that you want to insert a complex structure whenever a DITA `prolog` element is inserted.

  For instance, if you need to insert the following structure inside `prolog` elements:

  ```
  <prolog>
    <author></author>
    <metadata>
        <keywords>
            <keyword></keyword>
            <keyword></keyword>
        </keywords>
    </metadata>
  </prolog>
  ```

  The configuration file should include the following:

  ```
  <elementProposals path="prolog" insertElements="author metadata"/>
  <elementProposals path="prolog/metadata" insertElements="keywords"/>
  <elementProposals path="prolog/metadata/keywords"
        insertElements="keyword, keyword"/>
  ```

- **Example 3: Limit Possible Elements**

  Suppose that you also want to limit the proposals for the `keywords` element to only allow the user to insert `audience` or `keyword` elements. The configuration file should include the following:

  ```
  <elementProposals path="prolog/metadata" insertElements="keywords"
            possibleElements="audience keywords"/>
  ```

Suppose that you want to simply restrict your users from inserting `image` elements inside DITA list item elements (`li`), but still propose all the other elements that are defined in the associated schema. The configuration file should look like this:

```
<elementProposals path="li" rejectElements="image" />
```

Examples: Configuring the Attributes Proposals

- **Example 1: Automatically Insert Attributes**

  Suppose that you want to insert an `id` attribute (with an empty value) whenever a DITA list item element (`li`) is inserted. The configuration file should include the following:

  ```
  <elementProposals path="li" insertAttributes="id"/>
  ```

- **Example 2: Limit Possible Attributes**

  Suppose that you also want to limit the number of choices for attributes that are presented to the user whenever a DITA list item element (`li`) is inserted. The configuration file should look like this:

  ```
  <elementProposals path="li" insertAttributes="id"
            possibleAttributes="id product platform audience"/>
  ```

  Suppose that you want to simply restrict your users from inserting `conref` attributes inside DITA topics (`topic` element), but still propose all the other attributes that are defined in the associated schema. The configuration file should look like this:

  ```
  <elementProposals path="topic" rejectAttributes="conref" />
  ```

Configuring the Proposals for Attribute and Element Values on page 1462
Customizing the Rendering of Elements on page 1464

Configuring the Proposals for Attribute and Element Values

Oxygen XML Editor includes support for configuring the proposed values that appear in the *Content Completion Assistant*. To do so, a configuration file is used, along with the associated schema, to add or replace possible values for attributes or elements that are proposed in the *Content Completion Assistant*.

For an example of a specific use-case, suppose that you want the *Content Completion Assistant* to propose several possible values for the language code when you use an `xml:lang` attribute.

Setting up the Content Completion Configuration File

To customize the configuration file for the *Content Completion Assistant*, follow these steps:

1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Document Type Association**. Select the particular document type, click the **Edit** button, and in the ***Classpath** tab* add a link to that `resources` folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.
   a. To easily create a new configuration file, you can use the *Content Completion Configuration* file template that is included in Oxygen XML Editor (**File** > **New** > **Framework templates** > **Oxygen Extensions** > **Content Completion Configuration**). The file template includes details about how each element and attribute is used in the configuration file.
   b. If a configuration file (`cc_config.xml`) already exists for the particular document type (in the `resources` folder), you can modify this existing file.
4. Make the appropriate changes to your custom configuration file.
5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).

6. Restart the application and open an XML document. In the *Content Completion Assistant* you should see your customizations.

   Tip: In some cases, you can simply use the **Refresh (F5)** action to test your customizations, without having to restart the application.

Configuring Proposed Values

For the purposes of adding or replacing the values that are proposed, the configuration file (`cc_config.xml`) includes a series of `match` instructions that will match an element or attribute name. You also have the possibility of using an attribute called `editable` on the `match` element to specify the editable state of the attribute values, as reflected in the ***Attributes** view* and the ***In-place Attributes Editor***. The possible values for the `editable` attribute are:

- `true` - The attribute values can be edited by choosing from a combo box or manually providing a value.
- `false` - The attribute values cannot be edited.
- `onlyAllowedItems` - The attribute values can be edited, but only by choosing from a list of proposed values, in a non-editable combo box.

A new value is specified inside one or more `item` elements, which are grouped inside an `items` element. The behavior of the `items` element is specified with the help of the `action` attribute, which can have any of the following values:

- `append` - Adds new values to appear in the proposals list (default value).
- `addIfEmpty` - Adds new values to the proposals list only if no other values are contributed by the schema.
- `replace` - Replaces the values contributed by the schema with new values to appear in the proposals list.

The values in the configuration file can be specified either directly or by calling an external XSLT file that will extract data from an external source.

Other Important Notes About the Configuration File

Important:

- This configuration file only affects the content completion assistance, not validation.
- To test the effects of your changes, you should restart the application.

Example: Specifying Values Directly

If you want to specify the values directly, the configuration file should look like this:

```
<!-- Replaces the values for an element with the local name "lg",
      from the given namespace -->
<match elementName="lg" elementNS="http://www.oxygenxml.com/ns/samples">
    <items action="replace">
        <item value="stanza"/>
        <item value="refrain"/>
    </items>
</match>

<!-- Adds two values for an attribute with the local name "type",
      from any namespace -->
<match attributeName="type" editable="onlyAllowedItems">
    <items>
        <item value="stanza"/>
        <item value="refrain"/>
    </items>
</match>
```

Example: Calling an External XSLT Script

If you want to collect values from an external XSLT script, the configuration file should include something like this:

```
<xslt href="../xsl/get_values_from_db.xsl" useCache="false" action="replace"/>
```

In this example, the `get_values_from_db.xsl` is executed to extract values from a database.

Tip: You can use `xsl:message` as a debugging mechanism. These messages are presented in the results area at the bottom of the application whenever the *Content Completion Assistant* is invoked.

Note: A comprehensive XSLT sample is included in the **Content Completion Configuration** file template.

Configuring Proposed Values in the Context Where the Content Completion was Invoked

A more complex scenario is if you want to choose the possible values to propose, depending on the context of the element in which the content completion was invoked.

Suppose that you want to propose certain possible values for one property (for example, *color*) and other values for another property (for example, *shape*). If the property represents a color, then the values should represent applicable colors, while if the property represents a shape, then the values should represent applicable shapes. See the following code snippets:

Your main document:

```
<sampleArticle>
  <!-- The possible values for @value should be "red" and "blue" -->
  <property name="color" value=""/>
  <!-- The possible values for @value should be "square" and "rectangle" -->
  <property name="shape" value=""/>
</sampleArticle>
```

The content completion configuration file:

```
<config xmlns="http://www.oxygenxml.com/ns/ccfilter/config">
    <match elementName="property" attributeName="value">
      <xslt href="get_values.xsl" useCache="false" action="replace"/>
    </match>
</config>
```

The stylesheet that defines the possible values based on the context of the property on which the content completion was invoked:

```
<xsl:stylesheet
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  xmlns:saxon="http://saxon.sf.net/"
  exclude-result-prefixes="xs"
  version="2.0">

  <xsl:param name="documentSystemID" as="xs:string"></xsl:param>
  <xsl:param name="contextElementXPathExpression" as="xs:string"></xsl:param>

  <xsl:template name="start">
    <xsl:apply-templates select="doc($documentSystemID)"/>
  </xsl:template>

  <xsl:template match="/">
   <xsl:variable name="propertyElement"
    select="saxon:eval(saxon:expression($contextElementXPathExpression, ./*))"/>

   <items>
     <xsl:if test="$propertyElement/@name = 'color'">
       <item value='red'/>
       <item value='blue'/>
     </xsl:if>
     <xsl:if test="$propertyElement/@name = 'shape'">
       <item value='rectangle'/>
       <item value='square'/>
     </xsl:if>
   </items>
  </xsl:template>
</xsl:stylesheet>
```

The `contextElementXPathExpression` parameter will be bound to an XPath expression that identifies the element in the context for which the content completion was invoked.

Configuring the Proposals for Elements and Attributes on page 1458
Customizing the Rendering of Elements on page 1464

Customizing the Rendering of Elements

In addition to the support for configuring the proposals that appear in the *Content Completion Assistant*, Oxygen XML Editor also includes support for customizing how the elements are rendered. You can do this by using the

XMLNodeRendererCustomizer API extension, but you can also use the same configuration file that is used to configure the content completion proposals.

For an example of a specific use-case, suppose that in DITA you want the names of paragraph elements (p) to be rendered as "**Paragraph**" instead of "**p**" in the various components in **Author** mode (such as in the ***Outline*** *view*, ***Elements*** *view*, ***Attributes*** *view*, and the breadcrumb navigation bar). To achieve this, you can use the `elementRenderings` element in the configuration file.

Setting up the Content Completion Configuration File

To customize the configuration file for the *Content Completion Assistant*, follow these steps:

1. Create a new `resources` folder (if it does not already exist) in the `frameworks` directory for the particular document type (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources`).
2. *Open the* ***Preferences*** *dialog box (****Options*** *>* ***Preferences****)* and go to **Document Type Association**. Select the particular document type, click the **Edit** button, and in the ***Classpath*** *tab* add a link to that `resources` folder (if it does not already exist).
3. Create a new configuration file or edit an existing one.
   a. To easily create a new configuration file, you can use the *Content Completion Configuration* file template that is included in Oxygen XML Editor (**File** > **New** > **Framework templates** > **Oxygen Extensions** > **Content Completion Configuration**). The file template includes details about how each element and attribute is used in the configuration file.
   b. If a configuration file (`cc_config.xml`) already exists for the particular document type (in the `resources` folder), you can modify this existing file.
4. Make the appropriate changes to your custom configuration file.
5. Save the file in the `resources` folder for the particular document type, using the fixed name: `cc_config.xml` (for example, `OXYGEN_INSTALL_DIR/frameworks/dita/resources/cc_config.xml`).
6. Restart the application and open an XML document. In the *Content Completion Assistant* you should see your customizations.

   Tip: In some cases, you can simply use the **Refresh (F5)** action to test your customizations, without having to restart the application.

Changing the Rendering of Elements (Their Names, Annotations, and Icons)

For the purposes of customizing how the content completion elements are rendered, you can use the `render` element inside a `elementRenderings` element to specify how element names, their annotations, and their icons are rendered.

You can use the following attributes for the `render` element:

- `element` - Identifies the element to be customized, in the form of a qualified name. If it does not have a prefix, it is considered to be from *noNamespace*.
- `as` - Provides the name (label) that will be displayed for the element in various components in **Author** mode (such as in the *Content Completion Assistant*, the breadcrumb navigation bar, the ***Full Tags*** *display mode*, and the ***Outline***, ***Elements***, ***Attributes*** views). This attribute is optional. If it is missing, the name of the element is used.
- `iconPath` - Optional attribute that specifies the icon for the element. This is shown in the *Content Completion Assistant* and the ***Outline*** *view* in **Author** mode. If it is a relative path, the full path of the icon image file will be computed starting from the directory of the configuration file (for example, a value of `"myImg.png"` will cause Oxygen XML Editor to load `"frameworks/$ {framework}/resources/myImg.png"`). If you want to access a built-in resource, the value can begin with a forward slash `"/"`, and the image file will be searched for in the Oxygen XML Editor classpath resources (for example,`"/images/OrderedList16.png"` will load an icon from the built-in Oxygen XML Editor *JAR* file resources.
- `xml:lang` - Optional attribute that could be used to render the same element differently, depending on the language. If there are multiple `render` elements for the same `element` attribute (element name) and the `xml:lang` attribute is missing on one of them, that one will be considered the default fallback value to be used if none of the others match the language specified in the interface.

Note: The default entry should be listed first, since the application tries to match them in sequence and the last match found is the one that is used.

For example, suppose that you want the name of DITA paragraph elements (p) to be rendered as "Paragraphe" if the language is French, "Absatz" if the language is German, and "Paragraph" if the language is English (or any other language). Your configuration file should look something like this:

```
<elementRenderings>
  <render element="p" as="Paragraph"/>
  <render element="p" as="Paragraphe" xml:lang="fr"/>
  <render element="p" as="Absatz" xml:lang="de"/>
</elementRenderings>
```

You can also use the configuration file to customize the annotations for elements. For this purpose, the `render` element also accepts the following element to change the tooltip annotations for an element (in both **Author** mode and **Text** mode):

- `annotation` - This element can be used within the `render` element to customize the tooltip annotations that are displayed for the element in various components in **Author** mode (such as tooltips shown in the *Content Completion Assistant* documentation window, the breadcrumb navigation bar, the ***Full Tags*** *display mode*, and the ***Outline***, ***Elements***, ***Attributes*** views), as well as the tooltips that are displayed when you hover over elements in **Text** mode. You can use HTML content to style the annotations (see the *example below*).

  Note: If this element is missing, the *styling for the annotations for that element is collected from the associated schema*.

Other Important Notes About the Configuration File for Rendering Elements

Important:

- This configuration file only affects the content completion assistance, not validation.
- To test the effects of your changes, you should restart the application, although in some cases, you can simply use the **Refresh (F5)** action to test your customizations.
- If the *framework* has an associated *style guide*, then the annotations defined in the configuration file will take precedence over those defined in the *style guide*. To check to see if your *framework* uses a *style guide*, look for the following folder: `${oXygenInstallDir}frameworks/${framework}/styleguide/`. If that folder exists, it is recommended that you make your annotation changes directly in the *style guide*, rather than in the configuration file.
- If an *XMLNodeRendererCustomizer API extension* has been implemented for the *framework* and a configuration file is also used, the rendering customization for an element will be the result of merging the two. For example, if the *XMLNodeRendererCustomizer* implementation customizes the element name, while the configuration file specifies an icon for the element, the properties of both customizations will be rendered. However, if both implementations define the same property (for example, both specify the rendering of an element name), the customizations defined in the configuration file take precedence.
- The rendering customizations defined in the configuration file also applies to aspects of the Oxygen XML Web Author interface.

Example: Changing the Rendering of an Element

Suppose that you want to render the name of the DITA `title` element to begin with a capital letter, use a custom icon for it, and provide specific documentation for that element in the various components in **Author** mode. The configuration file should look like this:

```
<elementRenderings>
   <render element="title"   as="Title"  iconPath="cimg/AcceptAll16.png">
      <annotation>
         <html xmlns="http://www.w3.org/1999/xhtml">
           <head>
             <title>Documentation for the Title Element</title>
           </head>
             <body>
           <p>A <i>heading</i> or <b>label</b> for the main parts of a topic</p>
             </body>
         </html>
             </annotation>
   </render>
   </elementRenderings>
```

Schema Annotations in Author Mode on page 555

Annotations for XML Elements and Attributes in Content Completion Assistant on page 1467

Annotations for XML Elements and Attributes in Content Completion Assistant

Oxygen XML Editor gathers documentation from the associated schemas (DTD, XML Schema, RelaxNG) and presents it for each element or attribute. For example, if you open the *Content Completion Assistant* for a recognized XML vocabulary, documentation is displayed for each element provided by the associated schema. Similar information is displayed when you hover over tag names presented in the ***Elements*** *view*. If you hover over attributes in the ***Attributes*** *view* you also see information about each attribute, gathered from the same schema.

If you have a *framework configuration* set up for your XML vocabulary, there is a special XML configuration file that can be added to provide additional documentation information or links to specification web pages for certain elements and attributes.

To provide this additional information in the *Content Completion Assistant*, follow these steps:

1. Create a new folder in the configuration directory for the document type.

   Example: `OXYGEN_INSTALL_DIR/frameworks/dita/styleguide`
2. Use the **New** document wizard to create a file using the **Content Completion Styleguide** file template (in the **Oxygen Extensions** section).
3. Save the file in the folder created in step 1, using the fixed name: `contentCompletionElementsMap.xml`.
4. *Open the* ***Preferences*** *dialog box (****Options*** *>* ***Preferences****)*, go to **Document Type Association**, and edit the document type configuration for your XML vocabulary. Now you need to indicate where Oxygen XML Editor will locate your mapping file by doing one of the following:
   - In the **Classpath** tab add a link to the newly created folder.
   - In the **Catalogs** tab *add a new catalog file*. The selected file needs to contain the following:

     ```
     <?xml version="1.0" encoding="UTF-8"?>
     <!DOCTYPE catalog PUBLIC "-//OASIS//DTD XML Catalogs V1.1//EN"
         "http://www.oasis-open.org/committees/entity/release/1.1/catalog.dtd">
     <catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
         <uri name="http://www.oxygenxml.com/{processed_dt_name}/styleguide/
     contentCompletionElementsMap.xml" uri="contentCompletionElementsMap.xml"/>
     </catalog>
     ```

     where *{processed_dt_name}* is the name of the document type in lower case and with spaces replaced by underscores.

     Note: If Oxygen XML Editor finds a mapping file in both locations, the one in the **Catalogs** tab takes precedence.
5. Make the appropriate changes to your custom mapping file.

   Example: You can look at how the DITA mapping file is configured: `OXYGEN_INSTALL_DIR/frameworks/dita/styleguide/contentCompletionElementsMap.xml`

   The associated XML Schema contains additional details about how each element and attribute is used in the mapping file.
6. Re-open the application and open an XML document.

In the *Content Completion Assistant*, you should see the additional annotations for each element.

</xsl:stylesheet>
```

CSS Support in Author Mode

Author editing mode supports most CSS 2.1 selectors, numerous CSS 2.1 properties, and some CSS 3 selectors. Oxygen XML Editor also supports stylesheets coded with the LESS dynamic stylesheet language. Also, some custom functions and properties that extend the W3C CSS specification, and are useful for URL and string manipulation, are available to developers who create **Author** editing *frameworks*.

Configuring and Managing Multiple CSS Styles

Oxygen XML Editor provides a **Styles** drop-down menu on the toolbar that allows you to select one *main (non-alternate) CSS style* and multiple *alternate CSS styles*. This makes it easy to change the look of the document as it appears in **Author** mode and the output without having to continually edit the CSS stylesheets.

An example of a common use case is when content authors want to use custom styling within a document. You can select a *main* CSS stylesheet that styles the whole document and then apply *alternate* styles, as layers, to specific parts of the document.

Managing the CSS Styles

The *main* and *alternate* styles that are listed in the **Styles** drop-down menu can be controlled in the ***Document Type*** *configuration dialog box*. To access it, follow these steps:

1. *Open the* ***Preferences*** *dialog box* .
2. Go to **Document Type Association**.
3. Select the appropriate document type and press the **Edit** button.

   Important: If you do not have access rights to the folder where the *framework* files are stored, you can either elevate read/write permissions on that *framework* folder or you can extend the *framework* and customize the CSS stylesheets in the extension. If you want to share the customized extension with the rest of your team, see *Sharing the Extended Framework* on page 1457.

The CSS styles (CSS files) associated with the particular document type are listed in the ***CSS*** *subtab* of the **Author** tab.

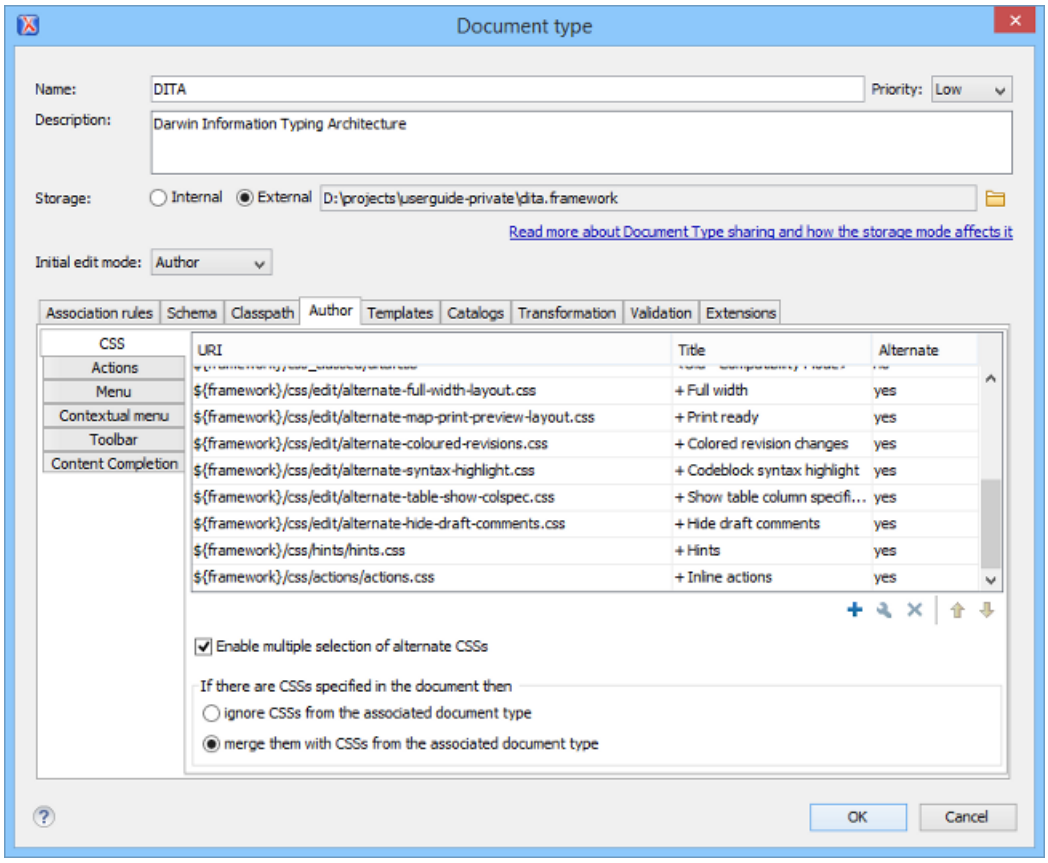

Figure 730: Main and Alternate CSS Styles in the Document Type Configuration Dialog Box

You can **Add**, **Edit**, or **Delete** styles from this dialog box to manage the *main* and *alternate* styles associated to the particular document type. You can also change the order of the styles by using the **Move Up** and **Move Down** buttons. This will also change the order that they appear in the **Styles** drop-down menu. The *alternate* styles are combined with the *main* CSS sequentially, in the order that they appear in this list. Therefore, if the same style rules are included in multiple CSS files, the rules that are defined in the last *alternate* style in this list will take precedence, since it is the last one to be combined (applied as a layer).

The **URI** column shows the path of each CSS file. The names listed in the **Styles** drop-down menu match the values in the **Title** column. The value in the **Alternate** column determines whether it is a *main* or *alternate* CSS. If the value is *no* it is a *main* CSS. If the value is *yes* it is an *alternate* CSS and the style can be combined with a *main* CSS or other *alternate* styles when using the **Styles** drop-down menu.

Note: To group alternate styles into categories (submenus), use a vertical bar character (|) in the **Title** column. You can use multiple vertical bars for multiple submenus. The text before each vertical bar will be rendered as the name of a submenu entry in the **Styles** drop-down menu, while the text after the final vertical bar will be rendered as the name of the style inside the submenu.

Example: Suppose that you want to add two alternate stylesheets in separate submenus, with the **Title** column set to `My Styles|User Assistance|Hints` and `My Styles|User Actions|Inline Actions`, respectively.

URI	Title	Alternate
${framework}/css/hints/hints.css	My Styles|User Assistance| Hints	yes
${framework}/css/actions/actions.css	My Styles|User Actions|Inline actions	yes

Oxygen XML Editor will add a `My Styles` submenu with two submenus (`User Assistance` that contains the `Hints` style, and `User Actions` that contains the `Inline Actions` style) in the **Styles** drop-down menu.

The ***Enable multiple selection of alternate CSSs*** *checkbox* at the bottom of the pane must be selected for the *alternate styles*to be combined. They are applied like layers and you can activate any number of them. If this option is not selected, the *alternate* styles are treated like *main CSS styles* and you can only select one at a time. By default, this option is selected. There are also a few options that allow you to specify how to handle the CSS if there are CSS styles specified in the document. You can choose to *ignore* or *merge* them.

The following rules apply for merging CSS styles:

- CSS files with the same title will be merged.
- CSS files without a title will contribute to all others.
- They are merged sequentially, in the order that they appear in the list.

Using the Styles Drop-Down Menu

You can use the **Styles** drop-down menu to select a *main style* that applies to the whole document and then select one or more *alternate styles* that behave like layers and are merged sequentially with the *main style*. The *main* styles are listed in the top section, while the *alternate styles* are listed in the bottom section. The styles (defined in their respective CSS files) that are selected in this drop-down menu are used to render your documents in **Author** mode and in the output.

Note: If you deselect the ***Enable multiple selection of alternate CSSs*** *option* in the **CSS** subtab of the ***Document Type*** *configuration dialog box*, the *alternate styles* are treated like *main CSS styles* and you can only select one at a time.

The selections from the **Styles** drop-down menu are persistent, meaning that Oxygen XML Editor will remember the selections when subsequent documents are opened.

EXAMPLE: CSS Styles in DITA

Oxygen XML Editor comes with a set of predefined CSS layer stylesheets for DITA documents (as well as some that are specifically for *DITA maps*). In the subsequent figure, a DITA document has the **Century** style selected for the *main CSS style* and the *alternate styles* **Full width**, **Show table column specification**, **Hints**, and **Inline actions** are combined for additive styling to specific parts of the document.

Tip: The **Hints** style displays tooltips throughout DITA documents that offer additional information to help you with the DITA structure. The **Inline actions** style displays possible elements that are allowed to be inserted at various locations throughout DITA documents.

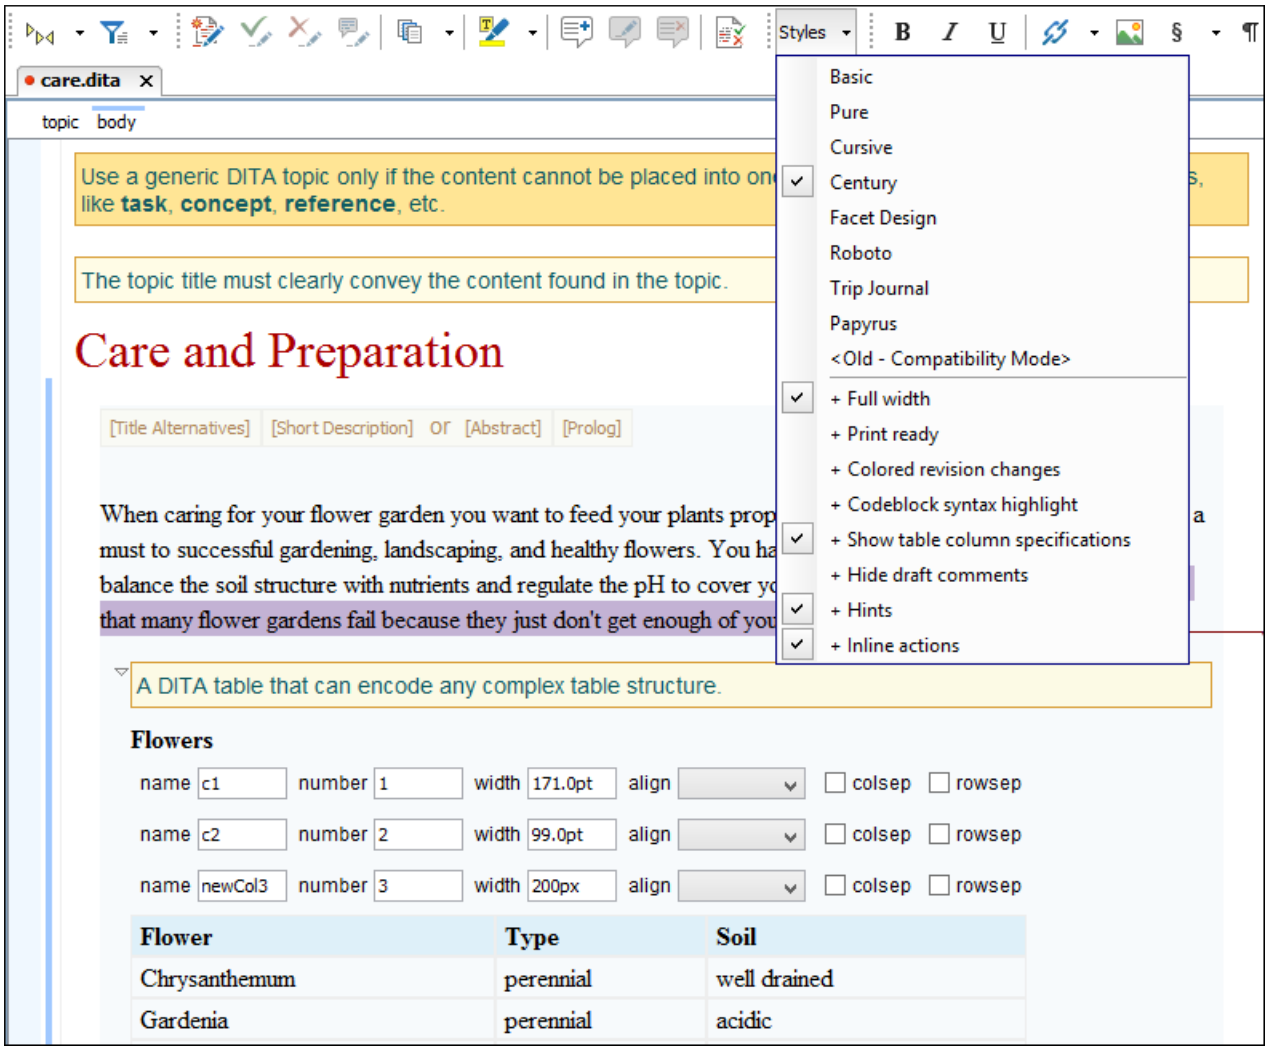

Figure 731: Styles Drop-down Menu in a DITA Document

CSS Subtab on page 62

Customizing the Main CSS of a Framework on page 1454

Handling CSS Imports

When a CSS document contains imports to other CSS documents, the references are also passed through the *XML Catalog* URI mappings to determine an indirect CSS referenced location.

Example: CSS Import

For example, if you can have a CSS import, such as:

```
@import "http://host/path/to/location/custom.css";
```

and then add your own *XML Catalog* file that maps the location to a custom CSS in the ***XML Catalog** preferences page*:

```
<uri name="http://host/path/to/location/custom.css"
      uri="path/to/custom.css"/>
```

Add a Custom Default CSS for Every XML Document

To add a custom CSS that is applied to every XML document, add a mapping in your *XML Catalog* file that looks like this:

```
<uri name="http://www.oxygenxml.com/extensions/author/css/userCustom.css"
      uri="path/to/custom.css"/>
```

This extra mapped CSS location will be parsed every time the application processes the CSS stylesheets used to render the opened XML document in the visual **Author** editing mode. This allows your custom CSS to be used without the need to modify all other CSS stylesheets contributed in the document type configuration.

Editor Variables in CSS Imports

You can use various *editor variables* in CSS imports. When editing an XML document with an associated CSS in **Author** mode, the editor variables will be expanded and resolved.

Example: Editor Variable in a CSS Import

For example, the following editor variable:

```
@import "${framework(DITA)}/custom.css";
```

is resolved in the DITA *framework* folder where the `custom.css` is placed.

oxygen Media Type

The CSS stylesheets can specify how a document is presented on different types of media (on the screen, paper, etc.) You can specify that some of the selectors from your CSS should be taken into account only in the Oxygen XML Editor **Author** mode and ignored in other media types. This can be accomplished by using the oxygen media type.

Example: *oxygen* Media Type

```
b{
 font-weight:bold;
 display:inline;
}

@media oxygen{
 b{
  text-decoration:underline;
 }
}
```

This example results in the text being bold if the document is opened in a web browser that does not recognize `@media oxygen`, while the text is bold and underlined when opened in Oxygen XML Editor **Author** mode.

You can also use the oxygen media type to specify CSS selectors to be applied in certain operating systems or platforms by using the `os` and `platform` properties. For example, you can specify one set of style rules for displaying Oxygen XML Editor in Windows, and another set of style rules for Mac OS. The supported properties are as follows:

- **os** - The possible values are: `win`, `linux`, or `mac`.
- **platform** - The possible values are: `standalone`, `eclipse`, or `webapp`.

Example: *os* and *platform* Properties

```
@media oxygen AND (os:"win") AND (platform:"standalone") {
    p{
        content:"PPP";
    }
}
```

Related Information:

@media Rule on page 1478

CSS At-Rules

Oxygen XML Editor supports some of the standard at-rules specified by CSS Level 2.1 and 3. The `@media` rule also include support for some style rules that are specific to Oxygen XML Editor.

@font-face At-Rule

Oxygen XML Editor allows you to use custom fonts in the **Author** mode by specifying them in the CSS using the `@font-face` media type. Only the `src` and `font-family` CSS properties can be used for this media type.

Example: *@font-face* Rule

```
@font-face{
    font-family:"Baroque Script";
    /*The location of the loaded TTF font must be relative to the CSS*/
    src:url("BaroqueScript.ttf");
}
```

@media Rule

The @media rule allows you to set different style rules for multiple types of media in the same stylesheet. For example, you can set the font size to be different on the screen than on paper. Oxygen XML Editor supports several media types, allowing you to set the style rules for presenting a document on various media (on screen, paper, etc.)

Supported Media Types

- `screen` - The styles marked with this media type are used only for rendering a document on screen.
- `print` - The styles marked with this media type are used only for printing a document.
- `all` - The styles marked with this media type are used for rendering a document in all supported types of media.
- `oxygen` - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode. For more information, see *oxygen Media Type* on page 1477.
- `oxygen-dark-theme` - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode when a dark theme is used (for example, *Graphite*).
- `oxygen-high-contrast-black` - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode on a Windows High Contrast Theme with a black background.
- `oxygen-high-contrast-white` - The styles marked with this media type are used only for rendering a document in the Oxygen XML Editor **Author** mode on a Windows High Contrast Theme with a white background.

Example: *@media* Rule

```
@media oxygen{
 b{
  text-decoration:underline;
 }
}
@media oxygen-high-contrast-white{
 b{
  font-weight:bold;
 }
}
```

Supported Properties

Oxygen XML Editor also supports a few properties to set specific style rules that depend upon the size of the visible area in **Author** mode. These supported properties are as follows:

- `min-width` - The styles selected in this property are applied if the visible area in **Author** mode is equal to or greater than the specified value.
- `max-width` - The styles selected in this property are applied if the visible area in **Author** mode is less than or equal to the specified value.

Example: *min-width* and *max-width* Properties

```
@media (min-width:500px){
 p{
    content:'XXX';
 }
}
@media (max-width:700px){
 p:after{
    content:'yyy';
 }
}
```

oxygen Media Type on page 1477

Standard W3C CSS Supported Features

Oxygen XML Editor supports most of the CSS Level 3 selectors and most of the CSS Level 2.1 properties

Supported CSS Selectors

The following table lists the CSS selectors that are supported in Oxygen XML Editor:

Expression	Name	CSS Level	Description / Example
`*`	Universal selector	CSS Level 2	Matches any element
`E`	Type selector	CSS Level 2	Matches any E element (i. e. an element with the local name E)
`E F`	Descendant selector	CSS Level 2	Matches any F element that is a descendant of an E element.
`E > F`	Child selectors	CSS Level 2	Matches any F element that is a child of an element E.
`E:lang(c)`	Language pseudo-class	CSS Level 2	Matches element of type E if it is in (human) language c (the document language specifies how language is determined).
`E + F`	Adjacent selector	CSS Level 2	Matches any F element immediately preceded by a sibling element E.
`E ~ F`	General sibling selector	CSS Level 3	Matches any F element preceded by a sibling element E.
`E[foo]`	Attribute selector	CSS Level 2	Matches any E element with the `"foo"` attribute set (whatever the value).
`E[foo="warning"]`	Attribute selector with value	CSS Level 2	Matches any E element whose `"foo"` attribute value is exactly equal to `"warning"`.
`E[foo~="warning"]`	Attribute selector containing value	CSS Level 2	Matches any E element whose `"foo"` attribute value is a list of space-separated values, one of which is exactly equal to `"warning"`.
`E[lang|="en"]`	Attribute selector containing hyphen separated values	CSS Level 2	Matches any E element whose `"lang"` attribute has a hyphen-separated list of values beginning (from the left) with `"en"`.
`E:before` and `E:after`	Pseudo elements	CSS Level 2	The `':before'` and `':after'` pseudo-elements can be used to

Expression	Name	CSS Level	Description / Example
			insert generated content before or after an element's content.
`E:before(n)` and `E:after(n)`	Pseudo elements	CSS Level 3	Multiple '`:before(n)`' and '`:after(n)`' pseudo-elements can be used to insert content before or after the content of an element (or other pseudo-element). For more information, see *the W3C CSS3 pseudo elements site*.
`E:first-child`	The first-child pseudo-class	CSS Level 2	Matches element E when E is the first child of its parent.
`E:not(s)`	Negation pseudo-class	CSS Level 2	An E element that does not match simple selector s.
`E:has`	Relational pseudo-class	CSS Level 4	The `:has()` relational pseudo-class is a functional pseudo-class that takes a relative selector as an argument. For more information, see *:has Relational Pseudo-Class* on page 1483.
`E:hover`	The hover pseudo-class	CSS Level 2	The `:hover` pseudo-class applies while the user designates an element with a pointing device, but does not necessarily activate it. When moving the pointing device over an element, all the parent elements up to the root are taken into account.
`E:focus`	The focus pseudo-class	CSS Level 2	The `:focus` pseudo-class applies while an element has the focus (accepts keyboard input).
`E:focus-within`	The generalized input focus pseudo-class	CSS Level 4	The `:focus-within` pseudo-class applies to elements for which the `:focus` pseudo-class applies. Additionally, the ancestors of an element that matches `:focus-within` also match.
`E#myid`	The ID selector	CSS Level 2	Matches any E element with ID equal to "myid". **Important:** Limitation: In Oxygen XML Editor the match is performed only taking into account the attributes with the exact name: *"id"*.
`E[att^="val"]`	Substring matching attribute selector	CSS Level 3	An E element whose `att` attribute value begins exactly with the string `val`.
`E[att$="val"]`	Substring matching attribute selector	CSS Level 3	An E element whose `att` attribute value ends exactly with the string `val`.

Expression	Name	CSS Level	Description / Example
`E[att*="val"]`	Substring matching attribute selector	CSS Level 3	An E element whose `att` attribute value contains the substring `val`.
`E:root`	Root pseudo-class	CSS Level 3	Matches the root element of the document. In HTML, the root element is always the HTML element.
`E:empty`	Empty pseudo-class	CSS Level 3	An E element that has no text or child elements.
`E:nth-child(n)`	The nth-child pseudo-class	CSS Level 3	An E element, the nth child of its parent.
`E:nth-last-child(n)`	The nth-last-child pseudo-class	CSS Level 3	An E element, the nth child of its parent, counting from the last one.
`E:nth-of-type(n)`	The nth-of-type pseudo-class	CSS Level 3	An E element, the nth sibling of its type.
`E:nth-last-of-type(n)`	The nth-last-of-type pseudo-class	CSS Level 3	An E element, the nth sibling of its type, counting from the last one.
`E:last-child`	The last-child pseudo-class	CSS Level 3	An E element, last child of its parent.
`E:first-of-type`	The first-of-type pseudo-class	CSS Level 3	An E element, first sibling of its type.
`E:last-of-type`	The last-of-type pseudo-class	CSS Level 3	An E element, last sibling of its type.
`E:only-child`	The only-child pseudo-class	CSS Level 3	An E element, only child of its parent.
`E:only-of-type`	The only-of-type pseudo-class	CSS Level 3	An E element, only sibling of its type.
`ns|E`	Element namespace selector	CSS Level 3	An element that has the local name E and the namespace given by the prefix `ns`. The namespace prefix can be bound to a URI by the at-rule: `@namespace ns "http://some_namespace_uri";` See *Namespace Selector* on page 1481.
`E!>F`	The subject selector	CSS Level 4 (experimental)	An element that has the local name E and has a child F. See *Subject Selector* on page 1483.

Namespace Selector

In the CSS 2.1 standard, the element selectors ignore the namespaces of the elements they are matching. Only the local name of the elements are considered in the selector matching process.

Oxygen XML Editor uses a different approach that is similar to the CSS Level 3 specification. If the element name from the CSS selector is not preceded by a namespace prefix it is considered to match an element with the same local name as the selector value and ANY namespace. Otherwise, the element must match both the local name and the namespace.

In CSS up to version 2.1 the name tokens from selectors are matching all elements from ANY namespace that have the same local name. Example:

```
<x:b xmlns:x="ns_x"/>
<y:b xmlns:y="ns_y"/>
```

Are both matched by the rule:

```
b {font-weight:bold}
```

Starting with CSS Level 3 you can create selectors that are namespace aware.

Example: Defining both prefixed namespaces and the default namespace

Given the namespace declarations:

```
@namespace sync "http://sync.example.org";
@namespace "http://example.com/foo";
```

In a context where the default namespace applies:

sync|A

represents the name A in the `http://sync.example.org` namespace.

|B

represents the name B that belongs to NO NAMESPACE.

***|C**

represents the name C in ANY namespace, including NO NAMESPACE.

D

represents the name D in the `http://example.com/foo` namespace.

Example: Defining only prefixed namespaces

Given the namespace declaration:

```
@namespace sync "http://sync.example.org";
```

Then:

sync|A

represents the name A in the `http://sync.example.org` namespace.

|B

represents the name B that belongs to NO NAMESPACE.

***|C**

represents the name C in ANY namespace, including NO NAMESPACE.

D

represents the name D in ANY namespace, including NO NAMESPACE.

Example: Defining prefixed namespaces combined with pseudo-elements

To match the `def` element its namespace will be declared, bind it to the *abs* prefix, and then write a CSS rule:

```
@namespace abs "http://www.oxygenxml.com/sample/documentation/abstracts";
```

Then:

abs|def

represents the name "def" in the `http://www.oxygenxml.com/sample/documentation/abstracts` namespace.

abs|def:before

represents the :before pseudo-element of the "def" element from the `http://www.oxygenxml.com/sample/documentation/abstracts` namespace.

Subject Selector

Oxygen XML Editor supports the subject selector described in CSS Level 4 (currently a working draft at W3C *http://www.w3.org/TR/selectors4/*). This selector matches a structure of the document, but unlike a compound selector, the styling properties are applied to the subject element (the one marked with "!") instead of the last element from the path.

The subject of the selector can be explicitly identified by appending an exclamation mark (!) to one of the compound selectors in a selector. Although the element structure that the selector represents is the same with or without the exclamation mark, indicating the subject in this way can change which compound selector represents the subject in that structure.

Example:

```
table! > caption {
  border: 1px solid red;
}
```

A border will be drawn to the table elements that contain a caption, as direct child.

This is different from:

```
table > caption {
  border: 1px solid red;
}
```

This draws a border around the caption.

Taking Processing Instructions into Account in CSS Subject Selectors

You can test for the existence of specific processing instructions (PI) in the child hierarchy of a subject selector.

For example:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";

chapter! > oxy|processing-instruction[important][level="high"]{
  color:red;
}
```

This would change the color of a DocBook chapter to red if it contains the `important` processing instruction:

```
<chapter>
   <title>A title</title>
   <?important level='high'?>
</chapter>
```

Descendant Selectors Limitation

Important: The current implementation has a known limitation. The general descendant selectors are taken into account as direct child selectors. For example, the following two CSS selectors are considered equivalent:

```
a! b c
```

and:

```
a! > b > c
```

Related Information:

:has Relational Pseudo-Class on page 1483

:has Relational Pseudo-Class

Oxygen XML Editor supports the CSS Level 4 subject selector (currently a working draft at W3C *http://www.w3.org/TR/selectors4/*), as described in *Subject Selector* on page 1483. Oxygen XML Editor also supports

the :has relational pseudo-class that has similar functionality and it can match an element by taking its child elements into account. For more information, see *https://drafts.csswg.org/selectors-4/#relational*.

You can create conditions that take into account the structure of the matching element.

Example: *has* Pseudo Class

```
table:has( tbody > thead){
 border: 1px solid red;
}
```

This example will result in a border being drawn for the table elements that contain at least a thead element in the tbody element.

Taking Processing Instructions into Account in CSS Subject Selectors

You can test for the existence of specific processing instructions (PI) in the child hierarchy of a subject selector.

For example:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";

chapter! > oxy|processing-instruction[important][level="high"]{
  color:red;
}
```

This would change the color of a DocBook chapter to red if it contains the important processing instruction:

```
<chapter>
   <title>A title</title>
   <?important level='high'?>
</chapter>
```

Descendant Selectors Limitation

Important: The current implementation has a known limitation. The general descendant selectors are taken into account as direct child selectors. For example, the following two CSS selectors are considered equivalent:

```
a! b c
```

and:

```
a! > b > c
```

Supported CSS Properties

Oxygen XML Editor validates all CSS 2.1 properties, but does not render *aural* and *paged* categories properties in **Author** mode, as well as some of the values of the *visual* category that are listed below under the **Ignored Values** column. For the Oxygen XML Editor-specific (extension) CSS properties, see *Oxygen XML Editor CSS Extensions* on page 1491.

Name	Rendered Values	Ignored Values
'background-attachment'	NONE	
'background-color'	<color> | inherit	transparent
'background-image'	<uri> | none | inherit	
'background-position'	top | right | bottom | left | center	<percentage> | *<length>*
'background-repeat'	repeat | repeat-x | repeat-y | no-repeat | inherit	
'background'	background-color | background-image | background-position | background-repeat	

Name	Rendered Values	Ignored Values
'border-collapse'	NONE	
'border-color'	<color> | inherit	transparent
'border-spacing'	NONE	
'border-style'	<border-style> | inherit	
'border-top' 'border-right' 'border-bottom' 'border-left'	[<border-width> || <border-style> || <border-color>] | inherit	
'border-top-color' 'border-right-color' 'border-bottom-color' 'border-left-color'	<color> | inherit	transparent
'border-top-style' 'border-right-style' 'border-bottom-style' 'border-left-style'	<border-style> | inherit	
'border-top-width' 'border-right-width' 'border-bottom-width' 'border-left-width'	<border-width> | inherit	
'border-width'	<border-width> | inherit	
'border'	[<border-width> || <border-style> || <border-color>] | inherit

'list-style'	['list-style-type'] | inherit	'list-style-position' || 'list-style-image'
'margin-right' 'margin-left'	<margin-width> | inherit | auto	

Name	Rendered Values	Ignored Values
'margin-top' 'margin-bottom'	<margin-width> | inherit	
'margin'	<margin-width> | inherit | auto	
'max-height'	NONE	
'max-width'	*<length>* | <percentage> | none | inherit - supported for *inline*, *block-level*, and replaced elements (such as images, tables, table cells)	
'min-height'	Absolute values, such as 230px, 1in, 7pt, 12em.	Values proportional to the parent element height, such as 30%
'min-width'	*<length>* | <percentage> | inherit - supported for *inline*, *block-level*, and replaced elements (such as images, tables, table cells)	
'outline-color'	[<color> | invert | inherit	
'outline-style'	[<border-style> | inherit	
'outline-width'	[<border-width> | inherit	
'outline'	[<outline-width> || <outline-style> || <outline-color>] | inherit	
'overflow'	NONE	
'padding-top' 'padding-right' 'padding-bottom' 'padding-left'	<padding-width> | inherit	
'padding'	<padding-width> | inherit	
'position'	absolute | fixed - supported for block display elements, relative - supported for *block* and *inline* display elements	absolute | fixed not supported for *inline* display elements
'quotes'	NONE	
'right'	*<length>* | <percentage> | inherit	auto
'table-layout'	auto	fixed | inherit
'text-align'	left | right | center | inherit	justify
'text-decoration'	none | [underline || overline || line-through] | inherit	blink
'text-decoration-style'	solid | double | dotted | dashed | wavy | inherit	

Name	Rendered Values	Ignored Values
'text-indent'	*<length>* | <percentage> | inherit	
'text-transform'	none | capitalize | uppercase | lowercase | inherit	
'top'	*<length>* | <percentage> | inherit	auto
'unicode-bidi'	bidi-override| normal| embed| inherit	
'vertical-align'	baseline | sub | super | top | text-top | middle | bottom | text-bottom | inherit	<percentage> | *<length>*
'visibility'	visible | hidden | inherit | -oxy-collapse-text	collapse
'white-space'	normal | pre | nowrap | pre-wrap | pre-line	
'width'	*<length>* | <percentage> | auto | inherit - supported for *inline*, *block-level*, and replaced elements (such as images, tables, table cells)	
'word-spacing'	NONE	
'z-index'	NONE	

<length> - Refers to distance measurements and is expressed in units such as `mm`, `cm`, `in`, `em`, `rem`, `ex`, `pc`, `pt`, `px`. For more information, see *the W3 CSS Level 3 length type specifications*.

Transparent Colors

CSS3 supports RGBA colors. The RGBA declaration allows you to set opacity (via the Alpha channel) as part of the color value. A value of `0` corresponds to a completely transparent color, while a value of 1 corresponds to a completely opaque color. To specify a value, you can use either a *real* number between `0` and 1, or a percent.

Example: RGBA Color

```
personnel:before {
    display:block;
    padding: 1em;
    font-size: 1.8em;
    content: "Employees";
    font-weight: bold;
    color:#EEEEEE;
    background-color: rgba(50, 50, 50, 0.6);
}
```

`attr()` Function: Properties Values Collected from the Edited Document

In CSS Level 2.1 you may collect attribute values and use them as content *only* for the pseudo-elements. For instance, the :before pseudo-element can be used to insert some content before an element. This is valid in CSS 2.1:

```
title:before{
  content: "[Audience Level: " attr(audience) "]";
```

```
}
```

If the `title` element from the XML document is:

```
<title audience="Expert">Changing the Timing Belt</title>
```

Then the title will be displayed as:

[Audience Level: Expert] Changing the Timimg Belt

In Oxygen XML Editor, the use of `attr()` function is available not only for the `content` property, but also for any other property. This is similar to the CSS Level 3 working draft: *http://www.w3.org/TR/2006/WD-css3-values-20060919/#functional*. The arguments of the function are:

`attr ( attribute_name , attribute_type , default_value )`

`attribute_name`

The attribute name. This argument is required.

`attribute_type`

The attribute type. This argument is optional. If it is missing, argument's type is considered `string`. This argument indicates what is the meaning of the attribute value and helps to perform conversions of this value. Oxygen XML Editor accepts one of the following types:

`color`

The value represents a color. The attribute may specify a color in various formats. Oxygen XML Editor supports colors specified either by name (`red`, `blue`, `green`, etc.) or as an RGB hexadecimal value #FFEEFF.

`url`

The value is a URL pointing to a media object. Oxygen XML Editor supports only images. The attribute value can be a complete URL, or a relative one to the XML document. Note that this URL is also resolved through the catalog resolver.

`integer`

The value must be interpreted as an integer.

`number`

The value must be interpreted as a float number.

`length`

The value must be interpreted as an integer.

`percentage`

The value must be interpreted relative to another value (length, size) expressed in percents.

`em`

The value must be interpreted as a size. 1 em is equal to the *font-size* of the relevant font.

`ex`

The value must be interpreted as a size. 1 ex is equal to the *height* of the **x** character of the relevant font.

`px`

The value must be interpreted as a size expressed in pixels relative to the viewing device.

`mm`

The value must be interpreted as a size expressed in millimeters.

`cm`

The value must be interpreted as a size expressed in centimeters.

`in`

The value must be interpreted as a size expressed in inches. 1 inch is equal to 2.54 centimeters.

`pt`

The value must be interpreted as a size expressed in points. The points used by CSS2 are equal to 1/72th of an inch.

`pc`

The value must be interpreted as a size expressed in picas. 1 pica is equal to 12 points.

`default_value`

This argument specifies a value that is used by default if the attribute value is missing. This argument is optional.

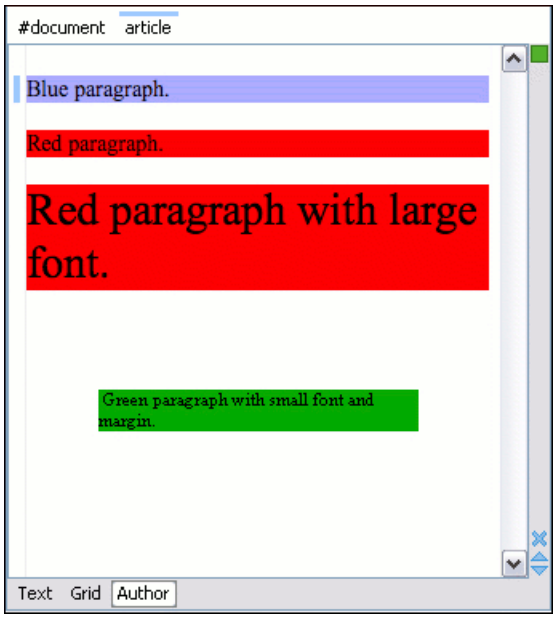
Example: *attr* Function

Consider the following XML instance:

```
<sample>
   <para bg_color="#AAAAFF">Blue paragraph.</para>
   <para bg_color="red">Red paragraph.</para>
   <para bg_color="red" font_size="2">Red paragraph with large font.</para>
   <para bg_color="#00AA00" font_size="0.8" space="4">
         Green paragraph with small font and margin.</para>
</sample>
```

The `para` elements have `bg_color` attributes with RGB color values (such as #AAAAFF). You can use the `attr()` function to change the elements appearance in the editor based on the value of this attribute:

```
background-color:attr(bg_color, color);
```



The attribute `font_size` represents the font size in *em* units. You can use this value to change the style of the element:

```
font-size:attr(font_size, em);
```

The complete CSS rule is:

```
para{
 display:block;
 background-color:attr(bg_color, color);
 font-size:attr(font_size, em);
 margin:attr(space, em);
}
```

The document is rendered as:

Oxygen XML Editor CSS Extensions

CSS stylesheets provide support for displaying documents. When editing non-standard documents, Oxygen XML Editor CSS extensions are useful.

Examples of how they can be used:

- Property for marking *foldable elements* in large files.
- Enforcing a display mode for the XML tags, regardless of the current mode selected by the user.
- Constructing a URL from a relative path location.
- String processing functions.

Built-in CSS Selectors

When Oxygen XML Editor renders content in the **Author** mode, it adds built-in CSS selectors (in addition to the CSS stylesheets linked in the XML or specified in the document type associated to the XML document). These built-in CSS selectors are processed before all other CSS content, but they can be overwritten if the CSS developer wants to modify a default behavior.

    background-color: transparent !important;
    color:blue !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 2px !important;
}

@media oxygen-high-contrast-black, oxygen-dark-theme{
    oxy|doctype {
        color:#D0E2F4 !important;
    }
}

oxy|error {
    display:-oxy-morph !important;
    -oxy-editable:false !important;
    white-space:pre !important;
    font-weight:bold !important;
    color: rgb(178, 0, 0) !important;
    -oxy-display-tags: none;
}

oxy|error:before {
    content:url(../images/ReferenceError.png) "[" !important;
    color: rgb(178, 0, 0) !important;
}
oxy|error[level='warn']:before {
    content:url(../images/ReferenceWarn.png) "[" !important;
    color: rgb(200, 185, 0) !important;
}

oxy|error[level='warn'] {
    color: rgb(200, 185, 0) !important;
}

oxy|error:after {
    content:"]" !important;
}

*[xlink|href]:before {
    content:url(../images/link.png);
    link: attr(xlink|href) !important;
}

/*No direct display of the MathML and SVG images.*/
svg|svg{
 display:inline !important;
    white-space: -oxy-trim-when-ws-only !important;
}

svg|svg * {
    display:none !important;
    white-space:normal !important;
}

mml|math{
 display:inline !important;
    white-space: -oxy-trim-when-ws-only !important;
}
mml|math mml|*{
    display:none !important;
    white-space: normal !important;
}

/*Text direction attributes*/
*[dir='rtl'] { direction:rtl; unicode-bidi:embed; }
*[dir='rlo'] { direction:rtl; unicode-bidi:bidi-override; }

*[dir='ltr'] { direction:ltr; unicode-bidi:embed; }
*[dir='lro'] { direction:ltr; unicode-bidi:bidi-override; }

@media oxygen-high-contrast-black, oxygen-dark-theme{
    xi|include:before,
    xi|include:after{
```

```
        color:#808080 !important;
    }
}
```

Example:

To show all entities in the **Author** mode as transparent, without a gray background, first define in your CSS after all imports the namespace:

```
@namespace oxy "http://www.oxygenxml.com/extensions/author";
```

and then add the following selector:

```
oxy|entity {
    background-color: inherit !important;
}
```

Additional CSS Selectors

Oxygen XML Editor provides support for selecting additional types of nodes. These custom selectors apply to: *document*, *doctype sections*, *processing-instructions*, *comments*, *CDATA sections*, *reference sections*, and *entities*. *Processing-instructions* are not displayed by default. To display them, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Author**, and select **Show processing instructions**.

Note: The custom selectors are presented in the default CSS for **Author** mode and all of their properties are marked with an *!important* flag. For this reason, you have to set the *!important* flag on each property of the custom selectors from your CSS to be applicable.

For the custom selectors to work in your CSS stylesheets, declare the **Author** mode extensions namespace at the beginning of the stylesheet documents:

```
@namespace oxy url('http://www.oxygenxml.com/extensions/author');
```

- The `oxy|document` selector matches the entire document:

  ```
  oxy|document {
      display:block !important;
  }
  ```

- The following example changes the rendering of doctype sections:

  ```
  oxy|doctype {
      display:block !important;
      color:blue !important;
      background-color:transparent !important;
  }
  ```

- To match the processing instructions, you can use the `oxy|processing-instruction` selector:

  ```
  oxy|processing-instruction {
      display:block !important;
      color:purple !important;
      background-color:transparent !important;
  }
  ```

  A processing instruction usually has a target and one or more pseudo attributes:

  ```
  <?target_name data="b"?>
  ```

  You can match a processing instruction with a particular target from the CSS using the construct:

  ```
  oxy|processing-instruction[target_name]
  ```

  You can also match the processing instructions having a certain target and pseudo attribute value, such as:

  ```
  oxy|processing-instruction[target_name][data="b"]
  ```

- The XML comments display in **Author** mode can be changed using the `oxy|comment` selector:

  ```
  oxy|comment {
      display:block !important;
      color:green !important;
      background-color:transparent !important;
  ```

```
}
```

- The `oxy|cdata` selector matches CDATA sections:

```
oxy|cdata{
    display:block !important;
    color:gray !important;
    background-color:transparent !important;
}
```

- The `oxy|entity` selector matches the entities content:

```
oxy|entity {
    display:morph !important;
    editable:false !important;
    color:orange !important;
    background-color:transparent !important;
}
```

  To match particular entities, use the `oxy|entity` selector in expressions such as:

```
oxy|entity[name='amp'],
oxy|entity[name='lt'],
oxy|entity[name='gt'],
oxy|entity[name='quot'],
oxy|entity[name='apos'],
oxy|entity[name^='#']{
    -oxy-display-tags: none;
}
```

- The *references to entities*, *XInclude*, and *DITA conrefs* and *conkeyrefs* are expanded by default in **Author** mode and the referenced content is displayed. The referenced resources are displayed inside the element or entity that refers to them.
  - You can use the `reference` property to customize the way these references are rendered in **Author** mode:

```
oxy|reference {
  border:1px solid gray !important;
}
```

  In the **Author** mode, content is highlighted when text contains *comments* and changes (if *Track Changes* was active when the content was modified).

  If this content is referenced, the **Author** mode does not display the highlighted areas in the new context. If you want to mark the existence of this comments and changes you can use the `oxy|reference[comments]`, `oxy|reference[changeTracking]`, and `oxy|reference[changeTracking][comments]` selectors.

  Note: Two artificial attributes (`comments` and `changeTracking`) are set on the reference node, containing information about the number of comments and tracked changes in the content.

  - The following example represents the customization of the reference fragments that contain comments:

```
oxy|reference[comments]:before {
  content: "Comments: " attr(comments) !important;
}
```

  - To match reference fragments based on the fact that they contain tracked changes inside, use the `oxy|reference[changeTracking]` selector.

```
oxy|reference[changeTracking]:before {
  content: "Change tracking: " attr(changeTracking) !important;
}
```

  - Here is an example of how you can set a custom color to the reference containing both tracked changes and comments:

```
oxy|reference[changeTracking][comments]:before {
  content: "Change tracking: " attr(changeTracking)
           " and comments: " attr(comments) !important;
}
```

Figure 732: Example: A Document Rendered Using these Rules

Additional CSS Properties

Oxygen XML Editor offers an extension of the standard CSS properties suited for content editing.

Folding Elements: -oxy-foldable

Oxygen XML Editor allows you to declare some elements to be *foldable*. This is especially useful when working with large documents organized in logical blocks, editing a large DocBook article or book, for instance. Oxygen XML Editor marks the *foldable* content with a small blue triangle. When you hover with your mouse pointer over this marker, a dotted line borders the collapsible content. The following actions are available in the **Folding** submenu of the contextual menu:

Toggle Fold
Toggles the state of the current fold.

Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))
Folds all the elements except the current element.

Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))
Folds the elements indented with one level inside the current element.

Expand Child Folds
Unfolds all child elements of the currently selected element.

Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))
Unfolds all elements in the current document.

To define the element whose content can be *folded* by the user, you must use the property: `-oxy-foldable:true;`. To define the elements that are *folded* by default, use the `-oxy-folded:true` property.

Note: The `-oxy-folded` property works in conjunction with the `-oxy-foldable` property. Thus, the `folded` property is ignored if the `-oxy-foldable` property is not set on the same element.

When collapsing an element, it is useful to keep some of its content visible (for example, a short description of the collapsed region). The property `-oxy-not-foldable-child` is used to identify the child element that is kept visible. It accepts as value an element name or a list of comma separated element names. The first child element from the XML document that appears in the list of element names will be identified as the not *foldable* child and displayed. If the element is marked as *foldable* (`-oxy-foldable:true;`) but it doesn't have the property `-oxy-not-foldable-child` or none of the specified *non-foldable* children exists, then the element is still *foldable*. In this case the element kept visible when *folded* will be the `before` pseudo-element.

Note: Deprecated properties `foldable`, `not-foldable-child`, and `folded` are also supported.

Example: Folding DocBook Elements

All the elements below can have a `title` child element and are considered to be logical sections. You mark them as being *foldable* leaving the `title` element visible.

```
set,
book,
part,
reference,
chapter,
preface,
article,
sect1,
sect2,
sect3,
sect4,
section,
appendix,
figure,
example,
table {
    -oxy-foldable:true;
    -oxy-not-foldable-child: title;
}
```

Placeholders for Empty Elements: -oxy-placeholder-content

Oxygen XML Editor displays the element name as pseudo-content for empty elements if the ***Show placeholders for empty elements*** *option* is selected in the **Author** preferences page and there is no *before* or *after* content set in the CSS for this type of element. There are two CSS properties that can be used to control the placeholders (`-oxy-placeholder-content` and `-oxy-show-placeholder`).

`-oxy-placeholder-content` CSS Property

To control the displayed pseudo-content for empty elements, you can use the `-oxy-placeholder-content` CSS property.

The following example would change the `keyword` element to be displayed as `key`:

```
keyword{
    -oxy-placeholder-content:"key";
}
```

Note: This CSS property accepts the ***${i18n(key)}*** localization editor variable, as in the following example:

```
-oxy-placeholder-content:"${i18n(id)}";
```

`-oxy-show-placeholder` CSS Property

The `-oxy-show-placeholder` property allows you to decide whether or not the placeholder will be shown. The possible values are:

- `always` - Always display placeholders.
- `default` - Always display placeholders if *before* or *after* content are not set is CSS.
- `inherit` - The placeholders are displayed according to the ***Show placeholders for empty elements*** *option* (if `before` and `after` content is not declared).
- no - Never display placeholders.

Note: Deprecated properties `show-placeholder` and `placeholder-content` are also supported.

Read-only Elements: `-oxy-editable` property

If you want to inhibit editing a certain element content, you can set the `-oxy-editable` (deprecated property `editable` is also supported) CSS property to `false`.

Display Elements: `-oxy-morph` Value

Oxygen XML Editor allows you to specify that an element has an `-oxy-morph` display type (deprecated `morph` property is also supported), meaning that the element is *inline* if all its children are *inline*.

Example: *-oxy-morph* Property Value

Suppose you have a **wrapper** XML element that allows users to set a number of attributes on all sub-elements. This element should have an *inline* or *block* behavior, depending on the behavior of its child elements:

```
wrapper{
 display:-oxy-morph;
}
```

Whitespace Property: `-oxy-trim-when-ws-only` Value

Oxygen XML Editor allows you to set the `white-space` property to `-oxy-trim-when-ws-only`, meaning that the leading and trailing whitespaces are removed.

Visibility Property: -oxy-collapse-text Value

Oxygen XML Editor allows you to set the value of the `visibility` property to `-oxy-collapse-text`, meaning that the text content of that element is not rendered. If an element is marked as `-oxy-collapse-text` you are not able to position the cursor inside it and edit it. The purpose of `-oxy-collapse-text` is to make the text value of an element editable only through a form control.

Example: *visibility* Property

The text value of an XML element will be edited using a text field form control. In this case, we want the text content not to be directly present in the **Author** visual editing mode:

```
title{
 content: oxy_textfield(edit, '#text', columns, 40);
 visibility:-oxy-collapse-text;
}
```

Cyrillic Counters: -oxy-lower-cyrillic

Oxygen XML Editor allows you to set the value of the `list-style-type` property to Cyrillic counters. For example, `-oxy-lower-cyrillic-ru`, `-oxy-lower-cyrillic-uk`, `-oxy-upper-cyrillic-ru` or `-oxy-upper-cyrillic-uk`, meaning that you can have Russian and Ukrainian counters.

Example: Cyrillic Counters

Counting list items with Cyrillic symbols:

```
li{
  display:list-item;
  list-style-type:-oxy-lower-cyrillic-ru;
}
```

Link Property: -oxy-link

Oxygen XML Editor allows you to declare some elements to be *links*. This is especially useful when working with many documents that reference each other. The links allow for an easy way to get from one document to another. Clicking the link marker will open the referenced resource in an editor.

To define the element that should be considered a link, you must use the `link` property on the `before` or `after` pseudo element. The value of the property indicates the location of the linked resource. Since links are usually indicated by the value of an attribute in most cases it will have a value similar to `attr(href)`

Example: DocBook Link Elements

The following elements are defined to be links on the `before` pseudo element and their values are defined by the value of an attribute.

```
*[href]:before{
```

```
    -oxy-link:attr(href);
    content: "Click " attr(href) " for opening" ;
}

ulink[url]:before{
    -oxy-link:attr(url);
    content: "Click to open: " attr(url);
}

olink[targetdoc]:before{
    -oxy-link: attr(targetdoc);
    content: "Click to open: " attr(targetdoc);
}
```

Display Tag Markers: -oxy-display-tags

Oxygen XML Editor allows you to choose whether tag markers of an element should never be presented or the current display mode should be respected. This is especially useful when working with `:before` and `:after` pseudo-elements, in which case the element range is already visually defined so the tag markers are redundant.

The property is named `-oxy-display-tags`, with the following possible values:

- *none* - Tags markers must not be presented regardless of the current *display mode.*.
- *default* - The tag markers will be created depending on the current *display mode.*.
- *inherit* - The value of the property is inherited from an ancestor element.

```
-oxy-display-tags
    Value: none | default | inherit
    Initial: default
    Applies to: all nodes(comments, elements, CDATA, etc.)
    Inherited: false
    Media: all
```

Example: *-oxy-display-tags* Property

In this example, the **para** element from DocBook uses a `:before` and `:after` element and its tag markers will not be visible.

```
para:before{
    content: "{";
}

para:after{
    content: "}";
}

para{
    -oxy-display-tags: none;
    display:block;
    margin: 0.5em 0;
}
```

Append Content Properties: `-oxy-append-content` / `-oxy-prepend-content`

`-oxy-append-content` Property

This property appends the specified content to the content generated by other matching CSS rules of lesser specificity. Unlike the `content` property, where only the value from the rule with the greatest specificity is taken into account, the `-oxy-append-content` property adds content to that generated by the lesser specificity rules into a new compound content.

Example:

```
element:before{
    content: "Hello";
}
element:before{
    -oxy-append-content: " World!";
}
```

The content shown before the `element` will be `Hello World!`.

`-oxy-prepend-content` Property

Prepends the specified content to the content generated by other matching CSS rules of lesser specificity. Unlike the `content` property, where only the value from the rule with the greatest specificity is taken into account, the -

`oxy-prepend-content` prepends content to that generated by the lesser specificity rules into a new compound content.

Example:

```
element:before{
    content: "Hello!";
}
element:before{
    -oxy-prepend-content: "said: ";
}
element:before{
    -oxy-prepend-content: "I ";
}
```

The content shown before the `element` will be `I said: Hello!`.

Custom Colors for Element Tags: -oxy-tags-color

By default, Oxygen XML Editor does not display element tags. You can use the **Partial Tags** button from the **Author** toolbar to control the amount of *displayed markup.*

To configure the default background and foreground colors of the tags, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Edit modes** > **Author**, and set the desired colors in the ***Tags background color*** and ***Tags foreground color*** options.

If you want to be more specific and configure the colors using your CSS, the `-oxy-tags-background-color` and `-oxy-tags-color` properties allow you to control the background and foreground colors for any particular XML element.

Example:

```
para {
    -oxy-tags-color:white;
    -oxy-tags-background-color:green;
}
title {
    -oxy-tags-color:yellow;
    -oxy-tags-background-color:black;
}
```

Style Element Property: -oxy-style

Oxygen XML Editor allows you to specify the style for an XML element. This is helpful if you want to embed CSS styling to XML elements directly in the XML file you are editing without having to edit the CSS files that are normally attached to the XML files. The property should have an XPath function for the value.

Example: *-oxy-style* Property

The following code snippet should be added in the CSS file that renders the files for your framework customization:

```
*{
   -oxy-style:attr(style);
}
```

Suppose you want to display the `title` elements in your XML document in the color red. You could add the following snippet directly in the XML document:

```
<title style="color:red;">My Memoirs</title>
```

Tip: The `style` attribute is supported by default in HTML5 documents.

Custom CSS Functions

The visual **Author** editing mode supports also a wide range of custom CSS extension functions.

`oxy_local-name()` Function
This function evaluates the local name of the current node.

It does not have any arguments.

Example: *oxy_local-name* Function

To insert the local name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_local-name() ": ";
}
```

`oxy_name()` Function

This function evaluates the qualified name of the current node.

It does not have any arguments.

Example: *oxy_name* Function

To insert a qualified name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_name() ": ";
}
```

`oxy_url()` Function

This function extends the standard CSS **url()** function by allowing you to specify additional relative path components (parameters **loc_1** to **loc_n**).

Oxygen XML Editor uses all these parameters to construct an absolute location. Note that any of the parameters that are passed to the function can be either relative or absolute locations. These locations can be expressed as String objects, functions, or *editor variables* (built-in or custom).

`oxy_url ( base_location , loc_1 , loc_2 )`

base_location

String representing the base location. If not absolute, will be solved relative to the CSS file URL.

loc_1 ... loc_n (optional)

Strings representing relative location path components.

Examples: *oxy_url* Function

The following function receives String objects as input parameters:

```
oxy_url('http://www.oxygenxml.com/css/test.css', '../dir1/',
        'dir2/dir3/', '../../dir4/dir5/test.xml')
```

and returns:

```
'http://www.oxygenxml.com/dir1/dir4/dir5/test.xml'
```

The following function receives the result of the evaluation of two other functions as parameters (for instance, this is useful if you have image references and you want to see thumbnail images stored in the same folder):

```
image[href]{
 content:oxy_url(oxy_base-uri(), oxy_replace(attr(href),
    '.jpeg', 'Thumbnail.jpeg'));
}
```

The following function uses an *editor variable* as the first parameter to point to the Oxygen XML Editor installation location:

```
image[href] {
    content: oxy_url('${oxygenHome}', 'logo.png');
}
```

Related Information:

Editor Variables on page 173

`oxy_base-uri()` Function

This function evaluates the base URL in the context of the current node.

It does not have any arguments and takes into account the `xml:base` context of the current node. See the *XML Base specification* for more details.

Example: *oxy_base-uri* Function

Suppose you have some image references but you want to see other thumbnail images that reside in the same folder (in **Author** mode):

```
image[href]{
 content:oxy_url(oxy_base-uri(), oxy_replace(attr(href),
    '.jpeg', 'Thumbnail.jpeg'));
}
```

`oxy_parent-url()` Function

This function evaluates the parent URL of a URL received as string.

`oxy_parent-url` (`URL`)

URL

The URL as string.

`oxy_capitalize()` Function

This function capitalizes the first letter of the text received as argument.

`oxy_capitalize` (`text`)

text

The text in which the first letter will be capitalized.

Example: *oxy_capitalize* Function

```
*:before{
  content: oxy_capitalize(oxy_name()) ": ";
}
```

This would insert the capitalized qualified name as static text content before the element.

`oxy_uppercase()` Function

This function transforms to upper case the text received as argument.

`oxy_uppercase` (`text`)

text

The text to be capitalized.

Example: *oxy_uppercase* Function

To insert the upper-cased qualified name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_uppercase(oxy_name()) ": ";
}
```

`oxy_lowercase()` Function

This function transforms to lower case the text received as argument.

`oxy_lowercase` (`text`)

text

The text to be lower cased.

Example: *oxy_lowercase* Function

To insert a lower-cased qualified name as static text content before the element, use this CSS selector:

```
*:before{
  content: oxy_lowercase(oxy_name()) ": ";
}
```

`oxy_concat()` Function

This function concatenates the received string arguments.

`oxy_concat` (`str_1` , `str_2`)

str_1 … str_n

The string arguments to be concatenated.

Example: *oxy_concat* Function

If an XML element has an attribute called **padding-left**:

```
 <p padding-left="20">...
```

and you want to add a padding before it with that specific amount specified in the attribute value:

```
*[padding-left]{
 padding-left:oxy_concat(attr(padding-left), "px");
}
```

`oxy_replace()` Function

This function is used to replace a string of text.

The `oxy_replace()` function has two signatures:

- `oxy_replace ( text , target , replacement )`

  This function replaces each substring of the text that matches the literal target string with the specified literal replacement string.

  text

  The text in which the replace will occur.

  target

  The target string to be replaced.

  replacement

  The string replacement.

  EXAMPLE: Suppose that you have image references but you want to see other thumbnail images that reside in the same folder in the visual **Author** editing mode:

  ```
  image[href]{
   content:oxy_url(oxy_base-uri(), oxy_replace(attr(href),
      '.jpeg', 'Thumbnail.jpeg'));
  }
  ```

- `oxy_replace ( text , target , replacement , isRegExp )`

  This function replaces each substring of the text that matches the target string with the specified replacement string.

  text

  The text in which the replace will occur.

  target

  The target string to be replaced.

  replacement

  The string replacement.

  isRegExp

  If *true* the target and replacement arguments are considered regular expressions, if *false* they are considered literal strings.

  EXAMPLE: Suppose that you want to use a regular expression to replace all space sequences with an underscore:

  ```
  image[title]{
   content:oxy_replace(attr(title), "\\s+", "_", true)
  }
  ```

`oxy_unparsed-entity-uri()` Function

This function returns the URI value of an unparsed entity name.

`oxy_unparsed-entity-uri ( unparsedEntityName )`

unparsedEntityName

The name of an unparsed entity defined in the DTD.

This function can be useful to display images that are referenced with unparsed entity names.

Example: *oxy_unparsed-entity-uri* Function

CSS for displaying the image in Author for an *imagedata* with *entityref* to an unparsed entity:

```
imagedata[entityref]{
content: oxy_url(oxy_unparsed-entity-uri(attr(entityref)));
}
```

oxy_attributes() Function

This function concatenates the attributes for an element and returns the serialization.

`oxy_attributes ( )`

Example: *oxy_attributes* Function

```
element{
  content:oxy_attributes();
}
```

For instance, if you have the following XML fragment: `<element att1="x" xmlns:a="2" x="""/>`, the CSS function will display:

```
att1="x" xmlns:a="2" x="""
```

oxy_substring() Function

This function is used to return a string of text.

The `oxy_substring()` function has two signatures:

- `oxy_substring ( text , startOffset )`

  Returns a new string that is a substring of the original **text** string. It begins with the character at the specified index and extends to the end of **text** string.

  text

  The original string.

  startOffset

  The beginning index, inclusive

- `substring ( text , startOffset , endOffset )`

  Returns a new string that is a substring of the original **text** string. The substring begins at the specified **startOffset** and extends to the character at index **endOffset** - 1.

  text

  The original string.

  startOffset

  The beginning index, inclusive.

  endOffset

  The ending index, exclusive.

Example: *oxy_substring* Function

`oxy_substring('abcd', 1)` returns the string `'bcd'`.

`oxy_substring('abcd', 4)` returns an empty string.

`oxy_substring('abcd', 1, 3)` returns the string `'bc'`.

If you only want to display part of an attribute value, for instance the part that comes before an **Appendix** string:

```
image[longdesc]{
 content: oxy_substring(attr(longdesc), 0,
          oxy_indexof(attr(longdesc), "Appendix"));
}
```

`oxy_getSomeText(text, length)` Function

This function allows you to truncate a long string and to set a maximum number of displayed characters.

The following properties are supported:

- **text** - Displays the actual text.
- **length** - Sets the maximum number of characters that are displayed.
- **endsWithPoints** - Specifies if the truncated text ends with ellipsis.

Example: *oxy_getSomeText* Function

If an attribute value is very large, you can trim its content before it is displayed as static content:

```
*[longdesc]:before{
  content: oxy_getSomeText(attr(longdesc), 200);
}
```

`oxy_indexof()` Function

This function is used to define searches.

The `oxy_indexof()` function has two signatures:

- `oxy_indexof ( text , toFind )`

  Returns the index within **text** string of the first occurrence of the **toFind** substring.

  text

  Text to search in.

  toFind

  The searched substring.

- `oxy_indexof ( text , toFind , fromOffset )`

  Returns the index within **text** string of the first occurrence of the **toFind** substring. The search starts from **fromOffset** index.

  text

  Text to search in.

  toFind

  The searched substring.

  fromOffset

  The index to start the search from.

Example: *oxy_indexof* Function

`oxy_indexof('abcd', 'bc')` returns 1.

`oxy_indexof('abcdbc', 'bc', 2)` returns 4.

If you only want to display part of an attribute value, for instance the part that comes before an **Appendix** string:

```
image[longdesc]{
 content: oxy_substring(attr(longdesc), 0,
          oxy_indexof(attr(longdesc), "Appendix"));
}
```

`oxy_lastindexof()` Function

This function is used to define last occurrence searches.

The `oxy_lastindexof()` function has two signatures:

- `oxy_lastindexof ( text , toFind )`

  Returns the index within **text** string of the rightmost occurrence of the **toFind** substring.

  text

  Text to search in.

toFind

The searched substring.

- `oxy_lastindexof ( text , toFind , fromOffset )`

  The search starts from **fromOffset** index. Returns the index within **text** string of the last occurrence of the **toFind** substring, searching backwards starting from the **fromOffset** index.

  text

  Text to search in.

  toFind

  The searched substring.

  fromOffset

  The index to start the search backwards from.

Example: *oxy_lastindexof* Function

`oxy_lastindexof('abcdbc', 'bc')` returns 4.

`oxy_lastindexof('abcdbccdbc', 'bc', 2)` returns 1.

If you only want to display part of an attribute value, for instance the part that comes before an **Appendix** string:

```
image[longdesc]{
 content: oxy_substring(attr(longdesc), 0,
          oxy_lastindexof(attr(longdesc), "Appendix"));
}
```

`oxy_xpath()` Function

This function is used to evaluate XPath expressions.

The `oxy_xpath()` function has the following signature:

- `oxy_xpath ( XPathExpression [, processChangeMarkers , value ] [, evaluate , value ])`

  It evaluates the given XPath 2.0 expression using Saxon 9 and returns the result. XPath expressions that depend on the cursor location can be successfully evaluated only when the cursor is located in the actual XML content. Evaluation fails when the current editing context is inside a referenced **xi:include** section or inside artificially referenced content (for example, DITA `conref` or `topicref` references).

  The parameters of the function are as follows:

  - A required expression parameter, which is the XPath expression to be evaluated.
  - An optional `processChangeMarkers` parameter, followed by its value, which can be either `true` or `false` (default value). When you set the parameter to `true`, the function returns the resulting text with all the change markers accepted (*delete* changes are removed and *insert* changes are preserved).
  - An optional `evaluate` parameter, followed by its value, which can be one of the following:
    - `dynamic` - Evaluates the XPath each time there are changes in the document.
    - `dynamic-once` - Separately evaluates the XPath for each node that matches the CSS selector. It will not re-evaluate the expression when changes are made to other nodes in the document. This will lead to improved performance, but the displayed content may not be updated to reflect the actual document content.
    - `static` - If the same XPath is evaluated on several nodes, the result for the first evaluation will be used for all other matches. Use this only if the XPath does not contain a relationship with the node on which the CSS property is evaluated. This will lead to improved performance, but the static displayed content may not be updated to reflect the actual document content.

Note: When XPath expressions are evaluated, the entities and `xi:include` elements are replaced with the actual content that is referenced. For example, consider the following code snippet:

```
<article>
  <xi:include href="section1.xml" xmlns:xi="http://www.w3.org/2001/XInclude"/>
</article>
```

where `section1.xml` contains the following content:

```
<section>
  <p>Referenced content</p>
</section>
```

The latter will be the actual content in which the XPath expression is executed.

Example: *oxy_xpath* Function

The following example counts the number of words from a paragraph (including *tracked changes*) and displays the result in front of it:

```
para:before{
  content:
   concat("|Number of words:",
    oxy_xpath(
        "count(tokenize(normalize-space(string-join(text(), '')), ' '))",
        processChangeMarkers,
       true),
    "| ");
}
```

Note: The `oxy_xpath()` function supports *editor variables*, as in the following example:

```
* {
    content:
    oxy_concat("Result: ",
        oxy_xpath('count(collection("${cfdu}/?select=*.xml"))')
    );
}
```

`oxy_action()` Function

This function allows you to define actions directly in the CSS, rather than referencing them from the associated framework.

The `oxy_action()` function is frequently used from the *oxy_button() function*.

The arguments received by the `oxy_action()` function are a list of properties that define an action. The following properties are supported:

- `name` - The name of the action. It will be displayed as the label for the button or menu item.
- `description` (optional) - A short description with details about the result of the action.
- `icon` (optional) - A path relative to the CSS pointing to an image (the icon for the action). The path can point to resources that are packed in Oxygen XML Editor (`oxygen.jar`) by starting its value with `/` (for example, `/images/Remove16.png`). It can also be expressed as an *editor variable*.
- `operation` - The name of the Java class implementing the *ro.sync.ecss.extensions.api.AuthorOperation* interface. There is also a variety of *predefined operations* that can be used.

  Note: If the name of the operation specified in the CSS is not qualified (has no Java package name), then it is considered to be one of the built-in Oxygen XML Editor operations from `ro.sync.ecss.extensions.commons.operations` package. If the class is not found in this package, then it will be loaded using the specified name.
- `arg-<string>` - All arguments with the `arg-` prefix are passed to the operation (the string that follows the `arg-` prefix is passed).
- `ID` - (optional) - The ID of the action from the *framework*. If this is specified, all others parameters are disregarded.

Example: *oxy_action* function inside an *oxy_button form control*:

```
oxy_button(
   action, oxy_action(
             name, 'Insert',
             description, 'Insert an element after the current one',
             icon, url('insert.png'),
             operation,
              'InsertFragmentOperation',
             arg-fragment, '<element>${caret}</element>',
             arg-insertLocation, '.',
             arg-insertPosition, 'After'),
             showIcon, true)
```

Example: *oxy_action* Function

You can also create a button form control directly from an `oxy_action` function:

```
oxy_action(
            name, 'Insert',
            description, 'Insert an element after the current one',
            operation, 'InsertFragmentOperation',
            arg-fragment, '<element>${caret}</element>',
            arg-insertLocation, '.',
            arg-insertPosition, 'After')
```

Tip: A code template is available to make it easy to add the `oxy_action` function with the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_action` code template.

Related Information:

Button Form Control on page 1514

The `oxy_button` built-in form control is used for graphical user interface objects that invoke a custom **Author** mode action (defined in the associated Document Type) referencing it by its ID, or directly in the CSS.

`oxy_action_list()` Function

This function allows you to define a sequential list of actions directly in the CSS, rather than referencing them from the associated framework.

The `oxy_action_list()` function is used from the *oxy_buttonGroup() function* or the *oxy_button() function*.

The arguments received by the `oxy_action_list()` function are a list of actions (executed sequentially) that are defined with the *oxy_action() function*. The following properties are supported in the `oxy_action_list()` function:

- `name` - The name of the action. The name of the first defined action will be displayed as the label for the button or menu item.
- `description` (optional) - A short description with details about the result of the action. The description of the first defined action will be displayed in a tooltip.
- `icon` (optional) - A path relative to the CSS pointing to an image (the icon for the action). The path can point to resources that are packed in Oxygen XML Editor (`oxygen.jar`) by starting its value with `/` (for example, `/images/Remove16.png`). It can also be expressed as an *editor variable*.
- `operation` - The name of the Java class implementing the *ro.sync.ecss.extensions.api.AuthorOperation* interface. There is also a variety of *predefined operations* that can be used.

  Note: If the name of the operation specified in the CSS is not qualified (has no Java package name), then it is considered to be one of the built-in Oxygen XML Editor operations from `ro.sync.ecss.extensions.commons.operations` package. If the class is not found in this package, then it will be loaded using the specified name.
- `arg-<string>` - All arguments with the `arg-` prefix are passed to the operation (the string that follows the `arg-` prefix is passed).
- `ID` - (optional) - The ID of the action from the *framework*. If this is specified, all others parameters are disregarded.

Example: *oxy_action_list* Function

```
oxy_action_list(
  oxy_action(
    name, 'Insert',
    description,
        'Insert an element after the current one',
    operation, InsertFragmentOperation,
    arg-fragment, '<element></element>',
    arg-insertLocation, '.',
    arg-insertPosition, 'After'
  ),
  oxy_action(
    name, 'Delete',
    description, 'Deletes the current element',
    operation, DeleteElementOperation
  )
)
```

Tip: A code template is available to make it easy to add the `oxy_action_list` function with the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_action_list` code template.

Related Information:

oxy_action() Function on page 1507
This function allows you to define actions directly in the CSS, rather than referencing them from the associated framework.

Button Group Form Control on page 1516
The `oxy_buttonGroup` built-in form control is used for a graphical user interface group of buttons that invokes one of several custom **Author** mode actions (defined in the associated Document Type) referencing it by its ID, or directly in the CSS.

`oxy_label()` Function

This function can be used in conjunction with the CSS `content` property to change the style of generated text.

The arguments of the function are *property name* - *property value* pairs. The following properties are supported:

- `text` - This property specifies the built-in form control you are using.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `background-color` - Specifies the background color of the form control. If the value of the `background-color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `styles` - Specifies styles for the form control. The values of this property are a set of CSS properties:
  - `font-weight`, `font-size`, `font-style`, `font`
  - `text-align`, `text-decoration`
  - `width`
  - `color`, `background-color`
  - `link` - For more information about this property see the *link property section*.

```
element{
    content: oxy_label(text, "Label Text", styles,
      "font-size:2em;color:red;link:attr(href);");
}
```

Instead of using the values of the `styles` property individually, you can define them in a CSS file as in the following example:

```
* {
    width: 40%;
    text-align:center;
}
```

Then refer that file with an `@import` directive, as follows:

```
elem {
  content: oxy_label(text, 'my_label', styles, "@import 'labels.css';")
}
```

CAUTION: Extensive use of the `styles` property may lead to performance issues.

If the text from an `oxy_label()` function contains new lines, for example `oxy_label(text, 'LINE1\A LINE2', width, 100px)`, the text is split in two. Each of the two new lines has the specified width of 100 pixels.

Note: The text is split after `\A`, which represents a new line character.

You can use the `oxy_label()` function together with a *built-in form control* function to create a form control based layouts.

Example: *oxy_label* Function

An example of a use case is if you have multiple attributes on a single element and you want use form controls on separate lines and style them differently. Consider the following CSS rule:

```
person:before {
```

```
  content: "Name:*" oxy_textfield(edit, '@name', columns, 20)
    "\A Address:" oxy_textfield(edit, '@address', columns, 20)
}
```

Suppose you only want the **Name** label to be set to **bold**, while you want both labels aligned to look like a table (the first column with labels and the second with a text field). To achieve this, you can use the `oxy_label()` to style each label differently.

```
person:before {
 content: oxy_label(text, "Name:*", styles, "font-weight:bold;width:200px")
          oxy_textfield(edit, '@name', columns, 20) "\A "
          oxy_label(text, "Address:", styles, "width:200px")
          oxy_textfield(edit, '@address', columns, 20)
}
```

Tip: A code template is available to make it easy to add the `oxy_label` function with the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_label` code template..

`oxy_link-text()` Function

You can use this function on the CSS `content` property to obtain a text description from the source of a reference.

By default, the `oxy_link-text()` function resolves DITA and DocBook references. For further details about how you can also extend this functionality to other *frameworks*, go to *Configuring an Extensions Bundle*.

DITA Support

For DITA, the `oxy_link-text()` function resolves the `xref` element and the elements that have a `keyref` attribute. The text description is the same as the one presented in the final output for those elements. If you use this function for a `topicref` element that has the `navtitle` and `locktitle` attributes set, the function returns the value of the `navtitle` attribute.

DocBook Support

For DocBook, the `oxy_link-text()` function resolves the `xref` element that defines a link in the same document. The text description is the same as the one presented in the final output for those elements.

Example: *oxy_link-text* Function

For the following XML and associated CSS fragments the `oxy_link-text()` function is resolved to the value of the `xreflabel` attribute.

```
<para><code id="para.id" xreflabel="The reference label">my code</code>
      </para>
<para><xref linkend="para.id"/></para>
```

```
xref {
    content: oxy_link-text();
}
```

If the text from the target cannot extracted (for instance, if the `href` is not valid), you can use an optional argument to display fallback text.

```
*[class~="map/topicref"]:before{
    content: oxy_link-text("Cannot find the topic reference");
    link:attr(href);
}
```

`oxy_unescapeURLValue(string)` Function

This function returns the unescaped value of a URL-like string given as a parameter.

For example, if the value contains `%20` it will be converted to a simple space character.

Example: *oxy_unescapeURLValue* Function

`oxy_unescapeURLValue("http://www.example.com/a%20simple%20example.html")` returns the following value:

```
http://www.example.com/a simple example.html
```

Arithmetic Functions
Arithmetic Functions that are supported.

You can use any of the arithmetic functions implemented in the *java.lang.Math* class (*http://download.oracle.com/javase/6/docs/api/java/lang/Math.html*).

In addition, the following functions are available:

Syntax	Details
oxy_add (*param1*, ... , *paramN*, *'returnType'*)	Adds the values of all parameters from *param1* to *paramN*.
oxy_subtract (*param1*, *param2*, ... , *paramN*, *'returnType'*)	Subtracts the values of parameters *param2* to *paramN* from *param1*.
oxy_multiply (*param1*, ... , *paramN*, *'returnType'*)	Multiplies the values of parameters from *param1* to *paramN*.
oxy_divide (*param1*, *param2*, *'returnType'*)	Performs the division of *param1* to *param2*.
oxy_modulo (*param1*, *param2*, *'returnType'*)	Returns the reminder of the division of *param1* to *param2*.

Note: The *returnType* can be *'integer'*, *'number'*, or any of the supported CSS measuring types.

Example: *oxy_multiply* Function

If you have an image with **width** and **height** specified on it, this will compute the number of pixels on it:

```
image:before{
 content: "Number of pixels: " oxy_multiply(attr(width), attr(height), "px");
}
```

Form Controls

Oxygen XML Editor provides a variety of built-in form controls that allow users to interact with documents with familiar user interface objects. For customization purposes, Oxygen XML Editor also supports *custom form controls in Java*.

For more information about form controls, watch our video demonstration:

Related Information:
Dynamically Add Form Controls Using a Styles Filter on page 1544

Audio File Player Form Control
The `oxy_audio` built-in form control is used for providing a mechanism to play audio clips.

The `oxy_audio` form control supports the following properties:

- `href` - The absolute or relative location of a resource. This property is mandatory. Relative values are resolved relative to the CSS. If you have media resources relative to the XML document, you can specify their paths like this:

  ```
  oxy_audio(href, oxy_url(oxy_base-uri(), 'ex.mp3')), width, 400px)
  ```

- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units.

Example: *oxy_audio* Form Control

```
object {
    content:
        oxy_audio(
            href, 'resources/audio.mp3',
            width, 200px),
}
```

Tip: To insert a sample of the `oxy_audio` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_audio` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Browser Form Control
The `oxy_browser` built-in form control is used for providing a mechanism to integrate HTML frames or interact with SVG documents directly in the **Author** mode editor. It can also be used to load HTML that executes JavaScript and from that JavaScript you can access the Oxygen XML Editor workspace. For example, you could use this method to change the value of an attribute, insert XML fragments, or open a new editor.

The `oxy_browser` form control supports the following properties:

- `href` - The absolute or relative location of a resource. This property is mandatory. Relative values are resolved relative to the CSS. If you have media resources relative to the XML document, you can specify their paths like this:

  ```
  oxy_browser(href, oxy_url(oxy_base-uri(), 'ex.svg')), width, 50%, height, 50%)
  ```
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units.
- `height` - Specifies the height of the form control area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units.

Example: *oxy_browser* Form Control

```
object {
  content:
    oxy_browser(
      href, 'http://example.page',
      width, 600px,
      height, 400px),
}
```

Tip: To insert a sample of the `oxy_browser` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_browser` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

Interacting with the Oxygen XML Editor Workspace

The `oxy_browser` form control also provides the possibility of creating custom form control without having to use the Java-based API. You can use the `oxy_browser` form control to load HTML that executes JavaScript. In the JavaScript, you can use some predefined global variables that provide a gateway between the JavaScript and the Oxygen XML Editor Java API. This allows you to perform changes in the document, open resources, and more, solely from the JavaScript.

Important: This will only work if the loaded HTML is located inside a *framework or plugin directory*, such as: *[OXYGEN_INSTALL_DIR]*`/frameworks/` or *[OXYGEN_INSTALL_DIR]*`/plugins/`.

The following global variables can be used:

- **authorAccess** - This object is an instance of *ro.sync.ecss.extensions.api.AuthorAccess*.
- **contextElement** - An instance of *ro.sync.ecss.extensions.api.node.AuthorNode*. The form control is added over this node.
- **pluginWorkspace** - An instance of *ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace*.
- **fcArguments** - A `java.util.Map` implementation with the properties (name and value pairs) passed on the form control function.
- **apiHelper** - A helper object for creating Java objects. It allows you to create Java objects from within the JavaScript code. These objects can then be passed to the Java methods as in the following example:

  ```
  var newAttrValue = apiHelper.newInstance(
            "ro.sync.ecss.extensions.api.node.AttrValue",
            ["normalizedValue", "rawValue", true]);
  authorAccess.getDocumentController().setAttribute(
          "counter", newAttrValue, contextElement);
  ```

```
...
```

You can also specify the constructor signature:

```
var newAttrValue = apiHelper.newInstance(
        "ro.sync.ecss.extensions.api.node.AttrValue
        (java.lang.String, java.lang.String, boolean)",
        ["normalizedValue", "rawValue", true]);
authorAccess.getDocumentController().setAttribute(
        "counter", newAttrValue, contextElement);
...
```

For more information, open the `form-controls.xml` file in the ***[OXYGEN_INSTALL_DIR]*/samples/form-controls** directory and go to section **11.1 - Interacting with the Oxygen Workspace**.

Warning: On Mac OS X, you need to use asynchronous calls to our API, due to the following JDK bug: *https://bugs.openjdk.java.net/browse/JDK-8087465*. By default, the API is called synchronously, but you can change this behavior for each API object by calling two methods: **sync()** and **async()**.

```
// By default, the methods are invoke synchronously.
var ctrl = authorAccess.getDocumentController();
try {
  // On Mac, methods that change the document must be executed asynchronously.
  ctrl.async();
  ctrl.setAttribute("counter", newAttrValue, contextElement);
} finally {
  ctrl.sync();
}
```

Listening for Changes in the Document

If the form control presents some information from the document (for example, the value of an attribute), then it needs to be notified on changes in the document so that it can update that information. To do this, follow these steps:

1. In the JavaScript, the **bridgeReady()** method is invoked as soon as the form control is loaded and our API bridge is installed. This is where you can add a listener:

```
function bridgeReady () {
  // We declare a member function for each method of the
  // ro.sync.ecss.extensions.api.AuthorListener interface (same function signature)
  var handler = {
    attributeChanged : function(event) {
      var node = event.getOwnerAuthorNode();
      var attrName = event.getAttributeName();

      if (node.equals(contextElement) && attrName === "counter") {
        init();
      }
    },
    contentDeleted : function(event) {},
    contentInserted : function(event) {}
  };

  // We create a proxy over an ro.sync.ecss.extensions.api.AuthorListener that will
  // delegate its methods to the JS object's functions.
  // We assign the listener to a global variable so that we can remove it later on,
  // on the dispose() method.
  authorDocumentListener = apiHelper.createProxyListener(
      "ro.sync.ecss.extensions.api.AuthorListener", handler);

  var ctrl = authorAccess.getDocumentController();

  // Add the proxy listener.
  ctrl.addAuthorListener(authorDocumentListener);
}
```

2. Since a listener was added on the document, it is important to remove it once the form control is not used anymore. When a form control is discarded, you can call the **dispose()** method from the JavaScript. This is where the previously created listener can be removed:

```
/**
 * The form control will not be used anymore. Clean up.
 */
function dispose() {
  // Dispose all added listeners.
  var ctrl = authorAccess.getDocumentController();
  ctrl.removeAuthorListener(authorDocumentListener);
}
```

Debugging JavaScript Used for Custom Form Controls

If you encounter unexpected results when using the *method described above*, you can debug the script by using the following guidelines:

- Calls to `alert("message.to.present")` or `console.log("message.to.present")` will be presented in the *Results panel*.
- You can install the ***Firebug*** *extension* by executing the following script:

```
{code:javascript}
function installFB() {
  if (!document.getElementById('FirebugLite')) {
    E = document['createElement' + 'NS'] && document.documentElement.namespaceURI;
    E = E ? document['createElement' + 'NS'](E, 'script')
          : document['createElement']('script');
    E['setAttribute']('id', 'FirebugLite');
    E['setAttribute']('src',
                      'https://getfirebug.com/' + 'firebug-lite.js' + '#startOpened');
    E['setAttribute']('FirebugLite', '4');
    (document['getElementsByTagName']('head')[0]
          || document['getElementsByTagName']('body')[0]).appendChild(E);
    E = new Image;
    E['setAttribute']('src', 'https://getfirebug.com/' + '#startOpened');
  }
}
{code}
```

Note: To force the *Browser Form Control* to reload after making changes to the JavaScript file, you need to use the **Reload page** action from the form control's contextual menu.

For more information about form controls, watch our video demonstration:

Button Form Control
The `oxy_button` built-in form control is used for graphical user interface objects that invoke a custom **Author** mode action (defined in the associated Document Type) referencing it by its ID, or directly in the CSS.

The `oxy_button` form control supports the following properties:

- `actionContext` - Specifies the context in which the action associated with the form control is executed. Its possible values are `element` (default value) and `caret`. If you select the `element` value, the context is the element that holds the form control. If you select the `caret` value, the action is invoked at the cursor location. If the cursor is not inside the element that holds the form control, the `element` value is selected automatically.
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `actionID` - The ID of the action, specified in the *document type association*, that is invoked when you click the button.

  Note: The element that contains the form control represents the context where the action is invoked.
- `action` - Defines an action directly, rather than using the `actionID` parameter to reference an action from the *document type association*. This property is defined using the *oxy_action function*.

  ```
  oxy_button(action, oxy_action(
            name, 'Insert',
            description, 'Insert an element after the current one',
            icon, url('insert.png'),
            operation, 'InsertFragmentOperation',
            arg-fragment, '<element>${caret}</element>',
            arg-insertLocation, '.',
            arg-insertPosition, 'After'
  ))
  ```

  Tip: You can also create a button form control *directly from an oxy_action function*.
- `action_list` - Defines a sequential list of actions directly, rather than using the `actionID` parameter to reference actions from the *document type association*. This property is defined using the *oxy_action_list function*.

  ```
  oxy_button(
      actionContext, caret,
  ```

```
          actions,
          oxy_action_list(
             oxy_action(
             name, 'SB',
             description, 'Surround fragment with multiple tags b -> i',
             operation, 'SurroundWithFragmentOperation',
             arg-fragment, '<b></b>'
),
           oxy_action(
             name, 'SI',
             operation, 'SurroundWithFragmentOperation',
             arg-fragment, '<i></i>'
          )
       )
)
```

Tip: When using the *oxy_action_list function*, the name and description of the first defined action will be what is displayed for the button. A *code template* is available to make it easy to add the *`oxy_action_list` function*.

- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- `transparent` - Flattens the aspect of the button form control, removing its border and background. The values of this property can be `true` or `false` (default value).
- `showText` - Specifies if the action text should be displayed on the button form control. If this property is missing then the button displays the icon only if it is available, or the text if the icon is not available. The values of this property can be `true` or `false`.

```
element {
  content: oxy_button(actionID, 'remove.attribute', showText, true);
}
```

- `showIcon` - Specifies if the action icon should be displayed on the button form control. If this property is missing then the button displays the icon only if it is available, or the text if the icon is not available. The values of this property can be `true` or `false`.

```
element {
  content: oxy_button(actionID, 'remove.attribute', showIcon, true);
}
```

- `enableInReadOnlyContext` - To enable *button form controls* or *groups of buttons form controls* this property needs to be set to `true`. This property can be used to specify areas as *read-only* (by setting the `oxy-editable` property to `false`). This is useful when you want to use an action that does not modify the context.
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_button(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_button* Form Control

```
button:before {
  content: "Label:"
     oxy_button(
         /* This action is declared in the document type
            associated with the XML document. */
         actionID, "insert.popupWithMultipleSelection");
}
```

Tip: To insert a sample of the `oxy_button` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_button` code template. Also, an `oxy_button_in_place_action` code template is available that inserts an `oxy_button` function that includes an `action` parameter.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Button Group Form Control
The `oxy_buttonGroup` built-in form control is used for a graphical user interface group of buttons that invokes one of several custom **Author** mode actions (defined in the associated Document Type) referencing it by its ID, or directly in the CSS.

The `oxy_buttonGroup` form control supports the following properties:

- `actionIDs` - The IDs of the actions that will be presented in the group of buttons.
- `actionID` - The ID of the action, specified in the *document type association*, that is invoked when you click the button.

  Note: The element that contains the form control represents the context where the action is invoked.
- `action_list` - Defines a sequential list of actions directly, rather than using the `actionID` parameter to reference actions from the *document type association*. This property is defined using the *oxy_action_list function*.

```
oxy_buttonGroup(
    label, 'A group of actions',
    icon, url('http://www.oxygenxml.com/img/icn_oxy20.png'),
    actions,
      oxy_action_list(
          oxy_action(
                name, 'Insert',
                description, 'Insert an element after the current one',
                operation, 'InsertFragmentOperation',
                arg-fragment, '<element></element>',
                arg-insertLocation, '.',
                arg-insertPosition, 'After'
          ),
          oxy_action(
                name, 'Delete',
                description, 'Deletes the current element',
                operation, 'DeleteElementOperation'
          )
      )
  )
```

  Tip: A *code template* is available to make it easy to add the *`oxy_action_list` function*.
- `label` - Specifies the label to be displayed on the button. This label can be translated using the *${i18n()} editor variable*.
- `icon` - The path to the icon to be displayed on the button.
- `actionContext` - Specifies the context in which the action associated with the form control is executed. Its possible values are `element` (default value) and `caret`. If you select the `element` value, the context is the element that holds the form control. If you select the `caret` value, the action is invoked at the cursor location. If the cursor is not inside the element that holds the form control, the `element` value is selected automatically.
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- `actionStyle` - Specifies what to display for an action in the form control. The values of this property can be `text` (default value), `icon`, or `both`.
- `tooltip` - Specifies a tooltip to be displayed when you hover over the form control.
- `transparent` - Makes the button transparent without any borders or background colors. The values of this property can be `true` or `false`.
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- `enableInReadOnlyContext` - To enable *button form controls* or *groups of buttons form controls* this property needs to be set to `true`. This property can be used to specify areas as *read-only* (by setting the `-oxy-editable` property to `false`). This is useful when you want to use an action that does not modify the context.
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_buttonGroup(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
```

```
  border: 1px solid red;
}
```

Example: *oxy_buttonGroup* Form Control

```
buttongroup:before {
  content:
    oxy_label(text, "Button Group:", width, 150px, text-align, left)
    oxy_buttonGroup(
       label, 'A group of actions',
       /* The action IDs are declared in the document type
          associated with the XML document. */
       actionIDs,
          "insert.popupWithMultipleSelection,insert.popupWithSingleSelection",
       actionStyle, "both");
}
```

Tip: To insert a sample of the `oxy_buttonGroup` form control in a CSS file (or LESS file)„ invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_buttonGroup` code template. Also, an `oxy_buttonGroup_in_place_action` code template is available that inserts an `oxy_buttonGroup` function that includes an `oxy_action_list` function.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*`/samples/form-controls`**.

For more information about form controls, watch our video demonstration:

Checkbox Form Control
The `oxy_checkbox` built-in form control is used for a graphical user interface box that you can click to enable or disable an option. A single checkbox or multiple checkboxes can be used to present and edit the value on an attribute or element.

The `oxy_checkbox` form control supports the following properties:

- `edit` - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note: You can set the value of the `visibility` property to `-oxy-collapse-text` to render the text only in the form control that the `oxy_editor` function specifies.
- `resultSeparator` - If multiple check-boxes are used, the separator is used to compose the final result. If not specified, the *space* character is used.
- `tooltips` - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable.
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- `values` - Specifies the values that are committed when the check-boxes are selected. If these values are not specified in the CSS, they are collected from the associated XML Schema.

  Note: Typically, when you use a comma in the values of a form control, the content that follows a comma is considered a new value. If you want to include a comma in the values, precede the comma with two backslashes. For example, `(values, '1\\, 2\\, 3, 4, edit, false)` will display a form control that has **1, 2, 3** for the first value and **4** for the second value.
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`..
- `uncheckedValues` - Specifies the values that are committed when check-boxes are not selected.
- `labels` - This property must have the same number of items as the `values` property. Each item provides a literal description of the items listed in the `values` property. These labels can be translated using the *${i18n()} editor variable*.. If this property is not specified, the `values` property is used as the label.
- `columns` - Controls the layout of the form control. The check boxes will be grouped in a number of columns equal to the given value.

- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_checkbox(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: Single *oxy_checkbox* Form Control

```
checkBox[attribute]:before {
    content: "A check box editor that edits a two valued attribute (On/Off)
              The values are specified in the CSS:"
        oxy_checkbox(
        edit, "@attribute",
        values, "On",
        uncheckedValues, "Off",
        labels, "On/Off");
}
```

Example: Multiple *oxy_checkbox* Form Controls

```
multipleCheckBox[attribute]:before {
    content: "Multiple checkboxes editor that edits an attribute value.
              Depending whether the check-box is selected,
              a different value is committed:"
        oxy_checkbox(
        edit, "@attribute",
        values, "true, yes, on",
        uncheckedValues, "false, no, off",
        resultSeparator, ","
        labels, "Present, Working, Started");
}
```

Tip: To insert a sample of the `oxy_checkbox` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_checkbox` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Combo Box Form Control
The `oxy_combobox` built-in form control is used for providing a graphical user interface object that is a drop-down menu of proposed values. This form control can also be used for a combination of a drop-down menu and an editable single-line text field.

The `oxy_combobox` form control supports the following properties:

- `edit` - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note: You can set the value of the `visibility` property to `-oxy-collapse-text` to render the text only in the form control that the `oxy_editor` function specifies.
- `columns` - Controls the width of the form control. The unit size is the width of the **w** character.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.

- `editable` - This property accepts the **true** and **false** values. In addition to a drop-down menu, the **true** value also generates an editable text field box that allows you to insert other values than the proposed ones. The **false** value generates a drop-down menu that only accepts the proposed values.
- `tooltips` - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable.
- `values` - Specifies the values that populate the list of proposals. If these values are not specified in the CSS, they are collected from the associated XML Schema..

  Note: Typically, when you use a comma in the values of a form control, the content that follows a comma is considered a new value. If you want to include a comma in the values, precede the comma with two backslashes. For example, `(values, '1\\, 2\\, 3, 4, edit, false)` will display a form control that has **1, 2, 3** for the first value and **4** for the second value.
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- `labels` - This property must have the same number of items as the `values` property. Each item provides a literal description of the items listed in the `values` property. These labels can be translated using the *${i18n()} editor variable*.

  Note: This property is only available for read-only combo boxes (the `editable` property is set to `false`).
- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

  ```
  p:before {
    content: oxy_combobox(hoverPseudoclassName, 'showBorder')
  }
  p:showBorder {
    border: 1px solid red;
  }
  ```
- `canRemoveValue` - If the value is set to `true` and the combo box is not editable, then a new `<Empty>` value is added in that combo box. This clears or removes the value being edited, depending on if it edits an element or attribute.
- onChange - Can be used to invoke an action when the value of the combo box changes. The action can be created in the CSS using the *`oxy_action()` function* or referenced from the *framework* by its ID. After the action is executed, the cursor remains in the combo box.

Example: *oxy_combobox* Form Control

```
comboBox:before {
    content: "A combo box that edits an attribute value.
              The possible values are provided from CSS:"
        oxy_combobox(
            edit, "@attribute",
            editable, false,
            values, "value1, value2, value3",
            labels, "Value no1, Value no2, Value no3",
            onChange, oxy_action(
                name, 'Insert',
                operation, 'XQueryUpdateOperation',
                arg-script, 'insert node <product>{xs:string(@attribute)}</product>
                          as last into .'));
}
```

Tip: To insert a sample of the `oxy_combobox` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_combobox` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Date Picker Form Control
The `oxy_datePicker` built-in form control is used for offering a text field with a calendar browser that allows the user to choose a certain date in a specified format.

The `oxy_datePicker` form control supports the following properties:

- `edit` - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note: You can set the value of the `visibility` property to `-oxy-collapse-text` to render the text only in the form control that the `oxy_editor` function specifies.
- `columns` - Controls the width of the form control. The unit size is the width of the **w** character.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- `format` - This property specifies the format of the inserted date. The pattern value must be a valid Java date (or date-time) format. If missing, the type of the date is determined from the associated schema.
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- `validateInput` - Specifies if the form control is validated. If you introduce a date that does not respect the format, the `datePicker` form control is rendered with a red foreground. By default, the input is validated. To disable the validation, set this property to `false`.
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_datePicker(edit, "@attribute", hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_datePicker* Form Control

```
date {
    content:
        oxy_label(text, "Date time attribute with
                  format defined in CSS: ", width, 300px)
        oxy_datePicker(
            columns, 16,
            edit, "@attribute",
            format, "yyyy-MM-dd");
}
```

Tip: To insert a sample of the `oxy_datePicker` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_datePicker` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

HTML Content Form Control
The `oxy_htmlContent` built-in form control is used for rendering HTML content. This HTML content is displayed as a graphical element shaped as a box. The shape of the box is determined by a given width and the height is computed based upon the length of the text.

The `oxy_htmlContent` form control supports the following properties:

- `href` - The absolute or relative location of a resource. The resource needs to be a well-formed HTML file.
- `id` - The unique identifier of an item. This is a `div` element that has a unique `id` and is a child of the `body` element. The `div` element is the container of the HTML content to be rendered by the form control.
- `content` - An alternative to the `href` and `id` pair of elements. It provides the HTML content that will be displayed in the form control.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_htmlContent(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

You can customize the style of the content using CSS that is either referenced by the file identified by the `href` property or is defined inline. If you change the HTML content or CSS and you want your changes to be reflected in the XML that renders the form control, then you need to refresh the XML file. If the HTML does not have an associated style, then a default text and background color will be applied.

Example: *oxy_htmlContent* Form Control

In the following example, the form control collects the content from the `p_description` `div` element found in the `descriptions.html` file. The box is 400 pixels wide and is displayed before a paragraph identified by the `intro_id` attribute value.

```
p#intro_id:before {
    content:
        oxy_htmlContent(
            href, "descriptions.html",
            id, "p_description",
            width, 400px);
}
```

An alternative example, using the `content` property:

```
p#intro_id:before {
    content:
        oxy_htmlContent(
            content, "<div style='font-weight:bold;'>My content</div>",
            width, 400px);
}
```

Tip: To insert a sample of the `oxy_htmlContent` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_htmlContent` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Pop-up Form Control
The `oxy_popup` built-in form control is used to offer a contextual menu that provides quick access to various actions. A pop-up form control can display single or multiple selections.

The `oxy_popup` form control supports the following properties:

- `edit` - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note: You can set the value of the `visibility` property to `-oxy-collapse-text` to render the text only in the form control that the `oxy_editor` function specifies.
- `rows` - This property specifies the number of rows that the form control presents.

  Note: If the value of the **rows** property is not specified, the default value of **12** is used.
- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.

  Note: This property is used for rendering in the **Author** mode.
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- `tooltips` - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable.

  Example:

  ```
  link:before{
   content: oxy_popup(
           edit, '@href',
           values, "Spring, Summer, Autumn, Winter",
           tooltips, "Iris${comma}Snowdrop, Gardenia${comma}Liliac,
               Chrysanthemum${comma}Salvia, Gerbera",
          selectionMode, single);
  }
  ```
- `values` - Specifies the values that populate the list of proposals. If these values are not specified in the CSS, they are collected from the associated XML Schema.

  Note: Typically, when you use a comma in the values of a form control, the content that follows a comma is considered a new value. If you want to include a comma in the values, precede the comma with two backslashes. For example, `(values, '1\\, 2\\, 3, 4, edit, false)` will display a form control that has **1, 2, 3** for the first value and **4** for the second value.
- `resultSeparator` - If multiple check-boxes are used, the separator is used to compose the final result. If not specified, the *space* character is used.

  Note: The value of the `resultSeparator` property cannot exceed one character.
- `selectionMode` - Specifies whether the form control allows the selection of a single value or multiple values. The predefined values of this property are `single` (default value) and `multiple`.
- `labels` - Specifies the label associated with each entry used for presentation. If this property is not specified, the **values** property is used instead.
- `columns` - Controls the width of the form control. The unit size is the width of the **w** character. This property is used for the visual representation of the form control.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `rendererSort` - Allows you to sort the values rendered on the form control label. The possible values of this property are `ascending` and `descending`.
- `editorSort` - Allows you to sort the values rendered on the form control. The possible values of this property are `ascending` and `descending`.
- `rendererSeparator` - Defines a separator used when multiple values are rendered. If not specified, the value of the `resultSeparator` property is used.
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.

- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_popup(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_popup* Form Control

```
popupWithMultipleSelection:before {
    content: " This editor edits an attribute value.
               The possible values are specified
    inside the CSS: "
        oxy_popup(
            edit, "@attribute",
            values, "value1, value2, value3, value4, value5",
            labels, "Value no1, Value no2, Value no3, Value no4, Value no5",
            resultSeparator, "|",
            columns, 10,
            selectionMode, "multiple",
            color, "blue",
            fontInherit, true);
    font-size:30px;
}
```

Tip: To insert a sample of the `oxy_popup` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_popup` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Text Area Form Control
The `oxy_textArea` built-in form control is used for entering multiple lines of text in a graphical user interface box. A text area may include optional syntax highlight capabilities to present the form control.

The `oxy_textArea` form control supports the following properties:

- `edit` - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note: You can set the value of the `visibility` property to `-oxy-collapse-text` to render the text only in the form control that the `oxy_editor` function specifies.
  - **#content** - This parameter is useful when an element has mixed or element-only content and you want to edit its content inside a text area form control.

    For example, if you have the following XML content:

    ```
    <codeblock outputclass="language-xml">START_TEXT<ph>phase</ph>
              <apiname><text>API</text></apiname></codeblock>
    ```

    and your CSS includes the following snippet:

    ```
    codeblock:before{
    content:
        oxy_textArea(
          edit, '#content',
          contentType, 'text/xml');
    }
    ```

    then the text area form control will edit the following fragment:

    ```
    START_TEXT<ph>phase</ph><apiname><text>API</text></apiname>
    ```

Note: When the value of the `edit` property is `#content`, the text area form control will also offer content completion proposals.

- **#content** - This parameter is useful when an element has mixed or element-only content and you want to edit its content inside a text area form control.

  For example, if you have the following XML content:

  ```
  <codeblock outputclass="language-xml">START_TEXT<ph>phase</ph>
            <apiname><text>API</text></apiname></codeblock>
  ```

  and your CSS includes the following snippet:

  ```
  codeblock:before{
  content:
      oxy_textArea(
        edit, '#content',
        contentType, 'text/xml');
  }
  ```

  then the text area form control will edit the following fragment:

  ```
  START_TEXT<ph>phase</ph><apiname><text>API</text></apiname>
  ```

  Note: When the value of the `edit` property is `#content`, the text area form control will also offer content completion proposals.
- `columns` - Controls the width of the form control. The unit size is the width of the **w** character.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- `rows` - This property specifies the number of rows that the form control presents. If the form control has more lines, you can scroll and see them all.
- `contentType` - Specifies the type of content for which the form control offers syntax highlighting. The following values are supported: `text/css; text/shell; text/cc; text/xquery; text/xml; text/python; text/xsd; text/c; text/xpath; text/javascript; text/xsl; text/wsdl; text/html; text/xproc; text/properties; text/sql; text/rng; text/sch; text/json; text/perl; text/php; text/java; text/batch; text/rnc; text/dtd; text/nvdl; text/plain.`
- `indentOnTab` - Specifies the behavior of the **Tab** key. If the value of this property is set to `true` (default value), the **Tab** key inserts characters. If it is set to `false`, **Tab** is used for navigation, jumping to the next editable position in the document.
- The `white-space` CSS property influences the value that you edit, as well as the from control size:
  - `pre` - The whitespaces and new lines of the value are preserved and edited. If the `rows` and `columns` properties are not specifies, the form control calculates its size on its own so that all the text is visible.
  - `pre-wrap` - The long lines are wrapped to avoid horizontal scrolling.

    Note: The `rows` and `columns` properties must be specified. If these are not specified, the form control considers the value to be `pre`.
  - `normal` - The white spaces and new lines are normalized.
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

  ```
  p:before {
    content: oxy_textArea(hoverPseudoclassName, 'showBorder')
  }
  p:showBorder {
    border: 1px solid red;
  }
  ```

Example: *oxy_textArea* Form Control

The following example presents a text area with CSS syntax highlighting that calculates its own dimension, and a second one with XML syntax highlighting with defined dimension.

```
textArea {
    visibility: -oxy-collapse-text;
    white-space: pre;
}

textArea[language="CSS"]:before {
    content: oxy_textArea(
      edit, '#text',
      contentType, 'text/css');
}

textArea[language="XML"]:before {
    content: oxy_textArea(
      edit, '#text',
      contentType, 'text/xml',
      rows, 10,
      columns, 30);
}
```

Tip: To insert a sample of the `oxy_textArea` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_textArea` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Text Field Form Control
The `oxy_textfield` built-in form control is used for entering a single line of text in a graphical user interface box. A text field may include optional content completion capabilities, used to present and edit the value of an attribute or an element.

The `oxy_textfield` form control supports the following properties:

- `edit` - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note: You can set the value of the `visibility` property to `-oxy-collapse-text` to render the text only in the form control that the `oxy_editor` function specifies.
- `columns` - Controls the width of the form control. The unit size is the width of the **w** character.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.
- `values` - Specifies the values that populate the list of proposals. If these values are not specified in the CSS, they are collected from the associated XML Schema.
- `tooltips` - Associates tooltips to each value in the `values` property. The value of this property is a list of tooltip messages separated by commas. If you want the tooltip to display a comma, use the `${comma}` variable.
- `tooltip` - Specifies a tooltip to be displayed when you hover over the form control.
- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `hasMultipleValues` - Specifies if the text field allows multiple values separated by spaces or just a single value.

Note: If the value is `false`, the *Content Completion Assistant* considers the entire text as the prefix for its proposals. If the value is `true` (the default value), the space is the delimiter for the values and thus it is not included in the prefix (the prefix will be whatever comes after the space).

For example, suppose the possible values for your text field are: `value a`, `value b`, and `other values`. If the `hasMultipleValues` property is set to `true` and the user enters `"value "` (notice the space character after 'value') in the text field, the *Content Completion Assistant* will suggest all three values because the prefix is whatever comes after the space, and in this case the user did not enter anything after the space. If the `hasMultipleValues` property was set to `false` for our example, the *Content Completion Assistant* would only suggest `value a` and `value b` because the space is considered part of the prefix.

- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_textfield(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_textfield* Form Control

```
element {
    content: "Label: "
        oxy_textfield(
            edit, "@my_attr",
            values, "value1, value2",
            color, "red",
            columns, 40);
}
```

Tip: To insert a sample of the `oxy_textfield` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_textfield` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

URL Chooser Form Control
The `oxy_urlChooser` built-in form control is used for a dialog box that allows you to select the location of local or remote resources. The inserted reference is made relative to the URL of the currently opened editor.

The `oxy_urlChooser` editor supports the following properties:

- `edit` - Lets you edit the value of an attribute, the text content of an element, or Processing Instructions (PI). This property can have the following values:
  - **@attribute_name** - The name of the attribute whose value is being edited. If the attribute is in a namespace, the value of the property must be a *QName* and the CSS must have a namespace declaration for the prefix.
  - **#text** - Specifies that the presented/edited value is the simple text value of an element.

    Note: You can set the value of the `visibility` property to `-oxy-collapse-text` to render the text only in the form control that the `oxy_editor` function specifies.
- `columns` - Controls the width of the form control. The unit size is the width of the **w** character.
- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the `%` character) length units. The `width` property takes precedence over the `columns` property (if the two are used together).
- `color` - Specifies the foreground color of the form control. If the value of the `color` property is `inherit`, the form control has the same color as the element in which it is inserted.
- `visible` - Specifies whether or not the form control is visible. The possible values of this property are `true` (default value) and `false`.

- `fontInherit` - This value specifies whether or not the form control inherits its font from its parent element. The values of this property can be `true` or `false` (default value). To make the form control inherit its font from its parent element, set the `fontInherit` property to `true`.
- `fileFilter` - string value that holds comma-separated file extensions. The URL chooser uses these extensions to filter the displayed files. A value such as `"jpg,png,gif"` is mapped to a single filter that will display all `jpg`, `png`, and `gif` files.
- `hoverPseudoclassName` - Allows you to change the way an element is rendered when you hover over a form control. The value is the name of a CSS pseudo-class. When you hover over the form control, the specified pseudo-class will be set on the element that contains the form control.

```
p:before {
  content: oxy_urlChooser(hoverPseudoclassName, 'showBorder')
}
p:showBorder {
  border: 1px solid red;
}
```

Example: *oxy_urlChooser* Form Control

```
urlChooser[file]:before {
    content: "A URL chooser editor that allows browsing for a URL.
          The selected URL is made relative to the currently edited file:"
        oxy_urlChooser(
        edit, "@file",
        columns 25);
}
```

Tip: To insert a sample of the `oxy_urlChooser` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_urlChooser` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Video Player Form Control
The `oxy_video` built-in form control is used for providing a mechanism to play videos.

The `oxy_video` form control supports the following properties:

- `href` - The absolute or relative location of a resource. This property is mandatory. Relative values are resolved relative to the CSS. If you have media resources relative to the XML document, you can specify their paths like this:

```
oxy_video(href, oxy_url(oxy_base-uri(), 'ex.mp4')), width, 400px, height, 300px)
```

- `width` - Specifies the width of the content area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units.
- `height` - Specifies the height of the form control area using relative (`em`, `ex`), absolute (`in`, `cm`, `mm`, `pt`, `pc`, `px`), and percentage (followed by the % character) length units.

Example: *oxy_video* Form Control

```
object {
    content:
        oxy_video(
            href, 'resources/video.mp4',
            width, 400px,
            height, 300px),
}
```

Tip: To insert a sample of the `oxy_video` form control in a CSS file (or LESS file), invoke the *Content Completion Assistant* by pressing **Ctrl + Space (Command + Space on OS X)** and select the `oxy_video` code template.

To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*/samples/form-controls**.

For more information about form controls, watch our video demonstration:

Implementing Custom Form Controls
If the built-in form controls are not sufficient for your needs, you can implement custom form controls in Java.

Custom Form Controls Implementation

You can specify custom form controls using the following properties:

- **rendererClassName** - The name of the class that draws the edited value. It must be an implementation of *ro.sync.ecss.extensions.api.editor.InplaceRenderer*. The renderer has to be a **SWING** implementation and can be used both in the standalone and Eclipse distributions.
- **swingEditorClassName** - You can use this property for the standalone (**Swing**-based) distribution to specify the name of the class used for editing. It is a **Swing** implementation of *ro.sync.ecss.extensions.api.editor.InplaceEditor*.
- **swtEditorClassName** - You can use this property for the Eclipse plugin distribution to specify the name of the class used for editing. It is a **SWT** implementation of the *ro.sync.ecss.extensions.api.editor.InplaceEditor*.

  Note: If the custom form control is intended to work in the Oxygen XML Editor standalone distribution, the declaration of **swtEditorClassName** is not required. The **renderer** (the class that draws the value) has different properties from the **editor** (the class that edits the value) because you can present a value in one way and edit it in another.
- **classpath** - You can use this property to specify the location of the classes used for a custom form control. The value of the **classpath** property is an enumeration of URLs separated by comma.
- **edit** - If your form control edits the value of an attribute or the text value of an element, you can use the `@attribute_name` and `#text` predefined values and Oxygen XML Editor will perform the commit logic by itself. You can use the `custom` value to perform the commit logic yourself.
- **saHeavyFormControlClassName** - This type of form control is effectively present at all times at its allocated bounds. This is useful if you need a form controls that renders dynamic or interactive SVG documents (for example, if you have an SVG document that displays tooltips when hovering over certain areas). It is also helpful if you want to use JavaFX, since JavaFX-based form controls are not compatible with the classic form control architecture.

  The value of this property is a class name that must implement the *ro.sync.ecss.extensions.api.editor.InplaceHeavyEditor* method. The *JAR* that contains this implementation can either be added in the ***Classpath** tab in the **Document Type Configuration** dialog box* for your particular *framework* or specified with the *classpath property*.

Example: Java Code

The following is a sample Java code for implementing a custom combo box form control that inserts an XML element in the content when the editing stops:

```
public class ComboBoxEditor  extends AbstractInplaceEditor {
  /**
   * @see ro.sync.ecss.extensions.api.editor.InplaceEditor#stopEditing()
   */
  @Override
   public void stopEditing() {
     Runnable customCommit =  new Runnable() {
      @Override
       public void run() {
        AuthorDocumentController documentController =
            context.getAuthorAccess().getDocumentController();
        documentController.insertXMLFragment( "<custom/>", offset);
       }
    };
    EditingEvent event =  new EditingEvent(customCommit,  true);
    fireEditingStopped(event);
  }
```

The custom form controls can use any of the predefined properties of the *built-in form controls*, as well as specified custom properties.

Example: CSS

The following is an example of how to specify a custom form control in the CSS:

```
myElement {
```

```
    content: oxy_editor(
        rendererClassName, "com.custom.editors.CustomRenderer",
        swingEditorClassName, "com.custom.editors.SwingCustomEditor",
        swtEditorClassName, "com.custom.editors.SwtCustomEditor",
        edit, "@my_attr",
        customProperty1, "customValue1",
        customProperty2, "customValue2"
    )
}
```

How to Implement Custom Form Controls

To implement a custom form control, follow these steps:

1. Download the Oxygen XML Editor SDK at *https://www.oxygenxml.com/oxygen_sdk.html*.
2. Implement the custom form control by extending *ro.sync.ecss.extensions.api.editor.InplaceEditorRendererAdapter*. You could also use *ro.sync.ecss.extensions.api.editor.AbstractInplaceEditor*, which offers some default implementations and listeners management.
3. Pack the previous implementation in a Java *JAR* library.
4. Copy the *JAR* library to the *[OXYGEN_INSTALL_DIR]*`/frameworks/[FRAMEWORK_DIR]` directory.
5. In Oxygen XML Editor, *open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Document Type Association**, edit the appropriate *framework*, and add the *JAR* library in the **Classpath** tab.
6. Specify the custom form control in your CSS, as described above.

Tip: To see more detailed examples and more information about how form controls work in Oxygen XML Editor, see the sample files in the following directory: ***[OXYGEN_INSTALL_DIR]*`/samples/form-controls`**.

For more information about form controls, watch our video demonstration:

Editing Processing Instructions Using Form Controls
Oxygen XML Editor allows you to edit *processing instructions*, *comments*, and *CDATA* by using the built-in editors.

Oxygen XML Editor allows you to edit *processing instructions*, *comments*, and *CDATA* by using the built-in editors.

Note: You can edit both the content and the attribute value from a *processing instruction*.

Example: Editing an Attribute from a Processing Instruction

PI content:

```
<?pi_target attr="val"?>
```

CSS:

```
oxy|processing-instruction:before {
    display:inline;
    content:
        "EDIT attribute: " oxy_textfield(edit, '@attr', columns, 15);
    visibility:visible;
}
oxy|processing-instruction{
    visibility:-oxy-collapse-text;
}
```

Custom CSS Pseudo-classes

You can set your custom CSS pseudo-classes on the nodes from the *AuthorDocument* model. These are similar to the normal XML attributes, with the important difference that they are not serialized, and by changing them the document does not create undo and redo edits - the document is considered unmodified. You can use custom pseudo-classes for changing the style of an element (and its children) without altering the document.

In Oxygen XML Editor they are used to hide/show the `colspec` elements from CALS tables. To take a look at the implementation, see:

1. *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/css/cals_table.css` (Search for `-oxy-visible-colspecs`)
2. The definition of action `table.toggle.colspec` from the DocBook *framework* makes use of the pre-defined *TogglePseudoClassOperation* **Author** mode operation.

Here are some examples:

Example: Controlling the visibility of a section using a pseudo-class

You can use a non standard (custom) pseudo-class to impose a style change on a specific element. For instance, you can have CSS styles matching the custom pseudo-class `access-control-user`, like the one below:

```
section {
  display:none;
}

section:access-control-user {
  display:block;
}
```

By setting the pseudo-class `access-control-user`, the element section will become visible by matching the second CSS selector.

Example: Coloring the elements at the current cursor location

You could create an *AuthorCaretListener* that sets the `caret-visited` pseudo-class to the element at the cursor location. The effect will be that all the elements traversed by the cursor become red.

```
*:caret-visited {
  color:red;
}
```

The API that you can use from the *CaretListener*:

ro.sync.ecss.extensions.api.AuthorDocumentController#setPseudoClass(java.lang.String, ro.sync.ecss.extensions.api.node.AuthorElement)

ro.sync.ecss.extensions.api.AuthorDocumentController#removePseudoClass(java.lang.String, ro.sync.ecss.extensions.api.node.AuthorElement)

Predefined Pseudo-Class Author Mode Operations

Pre-defined ***Author*** *mode operations* can be used directly in your *framework* to work with custom pseudo-classes:

1. *TogglePseudoClassOperation*
2. *SetPseudoClassOperation*
3. *RemovePseudoClassOperation*

Debugging CSS Stylesheets

To assist you with debugging and customizing CSS stylesheets the **Author** mode includes a ***CSS Inspector*** *view* to examine the CSS rules that match the currently selected element.

This tool is similar to the Inspect Element development tool that is found in most browsers. The **CSS Inspector** view allows you to see how the CSS rules are applied and the properties defined. Each rule that is displayed in this view includes a link to the line in the CSS file that defines the styles for the element that matches the rule. You can use the link to open the appropriate CSS file and edit the style rules. Once you have found the rule you want to edit, you can click the link in the top-right corner of that rule to open the CSS file in the editor.

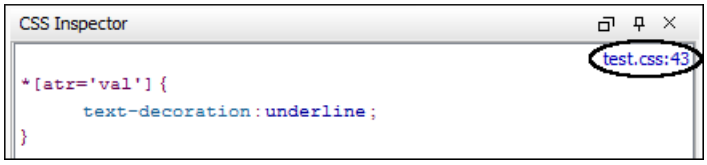

Figure 733: CSS Inspector View

There are two ways to open the CSS Inspector view:

1. Select **CSS Inspector** from the **Window** > **Show View** menu.
2. Select the **Inspect Styles** action from the contextual menu in **Author** mode.

Related Information:

CSS Inspector View on page 276

Creating and Running Automated Tests

If you have developed complex custom *plugin* or *framework* (document types), the best way to test your implementation and ensure that further changes will not interfere with the current behavior is to make automated tests for your customization.

An Oxygen XML Editor standalone installation includes a main `oxygen.jar` library located in the *[OXYGEN_INSTALL_DIR]*. That *JAR* library contains a base class for testing developer customizations named: *ro.sync.exml.workspace.api.PluginWorkspaceTCBase*.

To develop *JUnit* tests for your customizations using the **Eclipse** workbench, follow these steps:

1. Create a new Eclipse Java project and copy to it the entire contents of the *[OXYGEN_INSTALL_DIR]*.
2. Add all *JAR* libraries present in the *[OXYGEN_INSTALL_DIR]*`/lib` directory to the **Java Build Path**->**Libraries** tab. Make sure that the main *JAR* library `oxygen.jar` or `oxygenAuthor.jar` is the first one in the Java classpath by moving it up in the **Order and Export** tab.
3. Click **Add Library** and add the *JUnit* and *JFCUnit* libraries.
4. Create a new Java class that extends *ro.sync.exml.workspace.api.PluginWorkspaceTCBase*.
5. Pass the following parameters on to the constructor of the super class:
   - `File installationFolder` - The file path to the main application installation directory. If not specified, it defaults to the folder where the test is started.
   - `File frameworksFolder` - The file path to the `frameworks` directory. It can point to a custom *framework* directory where it resides.
   - `File pluginsFolder` - The file path to the `plugins` directory. It can point to a custom *plugin* directory where it resides.
   - `File optionsFolder` - The folder that contains the application options. If not specified, the application will auto-detect the location based on the started product ID.
   - `String licenseKey` - The license key used to license the test class.
   - `int productID` - The ID of the product and should be one of the following: `PluginWorkspaceTCBase.XML_AUTHOR_PRODUCT`, `PluginWorkspaceTCBase.XML_EDITOR_PRODUCT`, or `PluginWorkspaceTCBase.XML_DEVELOPER_PRODUCT`.
6. Create test methods that use the API in the base class to open XML files and perform various actions on them. Your test class could look something like this:

```
public class MyTestClass extends PluginWorkspaceTCBase {

/**
 * Constructor.
 */
public MyTestClass() throws Exception {
 super(null, new File("frameworks"), new File("plugins"), null,
"------START-LICENSE-KEY------\n" +
 "\n" +

 "\n" +
 "Company=\n" +
 "\n" +
 "Category=Enterprise\n" +
 "\n" +
 "Component=XML-Editor, XSLT-Debugger, Saxon-SA\n" +
 "\n" +
 "Version=14\n" +
 "\n" +
 "Number_of_Licenses=1\n" +
 "\n" +
 "Date=09-04-2012\n" +
 "\n" +
 "Trial=31\n" +
 "\n" +
 "SGN=MCwCFGNoEGJSeiC3XCYIyalvjzHhGhhqAhRNRDpEu8RIWb8icCJO7HqfVP4++A\\=\\=\n" +
 "\n" +
"-------END-LICENSE-KEY-------",
 PluginWorkspaceTCBase.XML_AUTHOR_PRODUCT);
 }

 /**
   * <p><b>Description:</b> TC for opening a file and using a bold operation</p>
   * <p><b>Bug ID:</b> EXM-20417</p>
   *
   * @author radu_coravu
```

```
   *
   * @throws Exception
   */
public void testOpenFileAndBoldEXM_20417() throws Exception {
      WSEditor ed = open(new File
("D:/projects/eXml/test/authorExtensions/dita/sampleSmall.xml").toURL());
     //Move caret
     moveCaretRelativeTo("Context", 1, false);

     //Insert <b>
     invokeAuthorExtensionActionForID("bold");
     assertEquals("<?xml version=\"1.0\" encoding=\"utf-8\"?>\n" +
       "<!DOCTYPE task PUBLIC \"-//OASIS//DTD DITA Task//EN\"

       "<task id=\"taskId\">\n" +
       "    <title>Task <b>title</b></title>\n" +
       "    <prolog/>\n" +
       "    <taskbody>\n" +
       "        <context>\n" +
       "            <p>Context for the current task</p>\n" +
       "        </context>\n" +
       "        <steps>\n" +
       "            <step>\n" +
       "                <cmd>Task step.</cmd>\n" +
       "            </step>\n" +
       "        </steps>\n" +
       "    </taskbody>\n" +
       "</task>\n" +
       "", getCurrentEditorXMLContent());
   }
}
```

API Frequently Asked Questions (API FAQ)

This section contains answers to common questions regarding the Oxygen XML Editor customizations using the *Oxygen SDK*, *Author Component*, or *Plugins*.

For additional questions, *contact us*. The preferred approach is via email because API questions must be analyzed thoroughly. We also provide code snippets, if they are required.

To stay up-to-date with the latest API changes, discuss issues and ask for solutions from other developers working with the *Oxygen SDK*, register on the *Oxygen-SDK mailing list*.

Add Custom Actions to the Contextual Menu?

Question

How do I add my own custom actions to the contextual menu using an API?

Answer

The API methods *WSAuthorEditorPageBase.addPopUpMenuCustomizer* and *WSTextEditorPage.addPopUpMenuCustomizer* allow you to customize the contextual menu shown either in the **Author** or **Text** modes. The API is available both in the standalone application and in the Eclipse plugin.

Here is an elegant way to add actions to the **Author** page from your Eclipse plugin extension:

1. Create a pop-up menu customizer implementation:

```
import org.eclipse.jface.action.ContributionManager;
import org.eclipse.ui.PlatformUI;
import org.eclipse.ui.menus.IMenuService;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.structure.AuthorPopupMenuCustomizer;
/**
* This class is used to create the possibility to attach certain
* menuContributions to the {@link ContributionManager}, which is used for the
* popup menu in the Author Page of the Oxygen Editor.<br />
* You just need to use the org.eclipse.ui.menus extension and add a
* menuContribution with the locationURI: <b>menu:oxygen.authorpage</b>
*/
public class OxygenAuthorPagePopupMenuCustomizer implements
        AuthorPopupMenuCustomizer {

    @Override
    public void customizePopUpMenu(Object menuManagerObj,
            AuthorAccess authoraccess) {
        if (menuManagerObj instanceof ContributionManager) {
 ContributionManager contributionManager = (ContributionManager) menuManagerObj;
```

```
            IMenuService menuService = (IMenuService) PlatformUI.getWorkbench()
                    .getActiveWorkbenchWindow().getService(IMenuService.class);

            menuService.populateContributionManager(contributionManager,
                    "menu:oxygen.authorpage");
            contributionManager.update(true);
        }
    }
}
```

2. Add a workbench listener and add the pop-up customizer when an editor is opened in the **Author** page:

```
Workbench.getInstance().getActiveWorkbenchWindow().getPartService()
.addPartListener(
    new IPartListener() {
      @Override
      public void partOpened(IWorkbenchPart part) {
        if(part instanceof ro.sync.exml.workspace.api.editor.WSEditor) {
          WSEditorPage currentPage = ((WSEditor)part).getCurrentPage();
          if(currentPage instanceof WSAuthorEditorPage) {
            ((WSAuthorEditorPage)currentPage).addPopUpMenuCustomizer
(new OxygenAuthorPagePopupMenuCustomizer());
          }
        }
      }
      ........
    });
```

3. Implement the extension point in your `plugin.xml` file:

```
<extension
       point="org.eclipse.ui.menus">
    <menuContribution
          allPopups="false"
          locationURI="menu:oxygen.authorpage">
       <command
             commandId="eu.doccenter.kgu.client.tagging.removeTaggingFromOxygen"
             style="push">
       </command>
    </menuContribution>
</extension>
```

Add Custom Callouts

Question

I want to highlight validation errors, instead of underlining them (for example, changing the text background color to light red or yellow). Also, I want to let Oxygen XML Editor write a note about the error type into the **Author** mode directly at the error position (for example, " [value "text" not allowed for attribute "type"] "). Is this possible using the API?

Answer

The Plugins API allows you to set a *ValidationProblemsFilter* that gets notified when automatic validation errors are available. Then you can map each of the problems to an offset range in the **Author** mode using the API *WSTextBasedEditorPage.getStartEndOffsets(DocumentPositionedInfo)*. For each of those offsets, you can add either persistent or non-persistent highlights. If you add persistent highlights, you can also customize callouts to appear for each of them. The downside is that they need to be removed before the document gets saved. The result would look something like this:

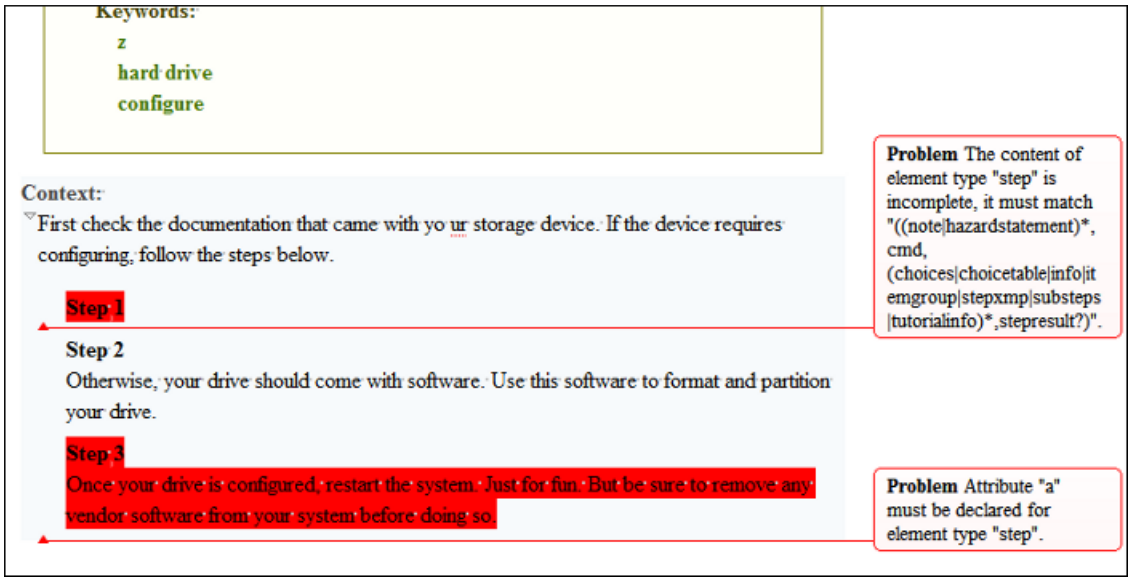

Figure 734: Custom Callouts with Persistent Highlights

Here is a working example:

```
/**
* Plugin extension - workspace access extension.
*/
public class CustomWorkspaceAccessPluginExtension
                    implements WorkspaceAccessPluginExtension {

/**
* @see ro.sync.exml.plugin.workspace.WorkspaceAccessPluginExtension
   #applicationStarted(
ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace)
*/
    public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
       pluginWorkspaceAccess.addEditorChangeListener
(new WSEditorChangeListener() {
          /**
           * @see WSEditorChangeListener#editorOpened(java.net.URL)
           */
          @Override
          public void editorOpened(URL editorLocation) {
            final WSEditor currentEditor = pluginWorkspaceAccess.getEditorAccess
(editorLocation, StandalonePluginWorkspace.MAIN_EDITING_AREA);
            WSEditorPage currentPage = currentEditor.getCurrentPage();
            if(currentPage instanceof WSAuthorEditorPage) {
              final WSAuthorEditorPage currentAuthorPage =
(WSAuthorEditorPage)currentPage;
              currentAuthorPage.getPersistentHighlighter().setHighlightRenderer
(new PersistentHighlightRenderer() {
                @Override
                public String getTooltip(AuthorPersistentHighlight highlight) {
                  return highlight.getClonedProperties().get("message");
                }
                @Override
                public HighlightPainter getHighlightPainter
(AuthorPersistentHighlight highlight) {
                  //Depending on severity could have different color.
                  ColorHighlightPainter painter = new ColorHighlightPainter
(Color.COLOR_RED, -1, -1);
                  painter.setBgColor(Color.COLOR_RED);
                  return painter;
                }
              });
        currentAuthorPage.getReviewController()
        .getAuthorCalloutsController().setCalloutsRenderingInformationProvider(
              new CalloutsRenderingInformationProvider() {
              @Override
    public boolean shouldRenderAsCallout(AuthorPersistentHighlight highlight) {
                //All custom highlights are ours
                return true;
              }
              @Override
    public AuthorCalloutRenderingInformation getCalloutRenderingInformation(
                  final AuthorPersistentHighlight highlight) {
                return new AuthorCalloutRenderingInformation() {
                  @Override
                  public long getTimestamp() {
                    //Not interesting
                    return -1;
                  }
```

```
                    @Override
                    public String getContentFromTarget(int limit) {
                      return "";
                    }
                    @Override
                    public String getComment(int limit) {
                      return highlight.getClonedProperties().get("message");
                    }
                    @Override
                    public Color getColor() {
                      return Color.COLOR_RED;
                    }
                    @Override
                    public String getCalloutType() {
                      return "Problem";
                    }
                    @Override
                    public String getAuthor() {
                      return "";
                    }
                    @Override
                    public Map<String, String> getAdditionalData() {
                      return null;
                    }
                  };
                }
              });
 currentEditor.addValidationProblemsFilter(new ValidationProblemsFilter() {

       */
      public boolean applicationClosing() {
        return true;
      }
    }
```

Add Custom Highlights to Content

Question

How can we add custom highlights to the document content in **Author** mode?

Answer

There are two types of highlights you can add:

1. **Non-Persistent Highlights** - Such highlights are removed when the document is closed and then re-opened.

   You can use the following API method:

   `ro.sync.exml.workspace.api.editor.page.author.WSAuthorEditorPageBase.getHighlighter()`

   to obtain an *AuthorHighlighter* that allows you to add a highlight between certain offsets with a specified painter.

   For example, you can use this support to implement your own spell checker with a custom highlight for the unrecognized words.
2. **Persistent Highlights** - Such highlights are saved in the XML content as processing instructions.

You can use the following API method:

`ro.sync.exml.workspace.api.editor.page.author.WSAuthorEditorPageBase.getPersistentHighlig`

to obtain an *AuthorPersistentHighlighter* class that allows you to add a persistent highlight between certain offsets, set new properties for a specific highlight, and render it with a specified painter.

For example, you can use this support to implement your own way of adding review comments.

Adding Custom Persistent Highlights on page 1454

Auto-Generate an ID When a Document is Opened or Created

Question

Is it possible to configure how the application generates ids? For project compliance we need ids having a certain format for each created topic.

Answer

This could be done implementing a *plugin* for Oxygen XML Editor using the Plugins SDK:

https://www.oxygenxml.com/oxygen_sdk.html#Developer_Plugins

There is a type of *plugin* called "Workspace Access" that can be used to add a listener to be notified when an editor is opened.

The implemented *plugin* would intercept the opened editor and editor page change events (which occur when a new editor is created) and generate a new ID attribute value on the root element.

The Java code would look like this:

```
pluginWorkspaceAccess.addEditorChangeListener(new WSEditorChangeListener() {
/**
* @see WSEditorChangeListener#editorOpened(java.net.URL)
*/
@Override
public void editorOpened(URL editorLocation) {
    WSEditor ed = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
        generateID(ed);
}
/**
* @see WSEditorChangeListener#editorPageChanged(java.net.URL)
*/
@Override
public void editorPageChanged(URL editorLocation) {
    WSEditor ed = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
        generateID(ed);
}

private void generateID(WSEditor ed) {
 if(ed.getCurrentPage() instanceof WSAuthorEditorPage) {
  WSAuthorEditorPage authorEditPage = (WSAuthorEditorPage) ed.getCurrentPage();
  AuthorDocumentController ctrl = authorEditPage.getDocumentController();
  AuthorElement root = ctrl.getAuthorDocumentNode().getRootElement();
   if(root.getAttribute("id") == null ||
!root.getAttribute("id").getValue().startsWith("generated_")) {
    ctrl.setAttribute("id", new AttrValue("generated_" + Math.random()), root);
        }
      }
    }

    }, PluginWorkspace.MAIN_EDITING_AREA);
```

Change the Default Track Changes (Review) Author Name

Question

How can we change the default author name used for *Tracked Changes* in the *Author Component*?

Answer

The *Track Changes* (Review) author name is determined in the following order:

1. **API** - The review user name can be imposed through the following API:

```
ro.sync.ecss.extensions.api.AuthorReviewController.setReviewerAuthorName(String)
```

2. **Options** - If the author name was not imposed from the API, it is determined from the ***Author*** *option set in the* ***Review*** *preferences page*.
3. **System properties** - If the author name was not imposed from the API or from the application options then the following system property is used:

```
System.getProperty("user.name")
```

So, to impose the *Track Changes* author, use one of the following approaches:

1. Use the API to impose the reviewer author name. Here is the online Javadoc of this method: *https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/AuthorReviewController.html#setReviewerAuthorName(java.lang.String)*
2. Customize the default options and set a specific value for the ***Author*** *name option set in the* ***Review*** *preferences page*.
3. Set the value of `user.name` system property when the applet is initializing and before any document is loaded.

Change the DOCTYPE of an Opened XML Document

Question

How to change the DOCTYPE of a document opened in the **Author** mode?

Answer

The following API:

`ro.sync.ecss.extensions.api.AuthorDocumentController.getDoctype()`

allows you to get the DOCTYPE of the current XML file opened in the **Author** mode.

There is also an API method available that would allow you to set the DOCTYPE back to the XML:

`ro.sync.ecss.extensions.api.AuthorDocumentController.setDoctype(AuthorDocumentType)`

Here is an example of how this solution would work:

```
AuthorDocumentType
dt = new AuthorDocumentType("article", "testSystemID", "testPublicID",
           "<!DOCTYPE article PUBLIC \"testPublicID\" \"testSystemID\">");
docController.setDoctype(dt);
```

Basically, you could take the entire content from the existing DOCTYPE,

`ro.sync.ecss.extensions.api.AuthorDocumentType.getContent()`

modify it to your needs, and create another `AuthorDocumentType` object with the new content and with the same public, system IDs.

For example, you could use this API is you want to add unparsed entities in the XML DOCTYPE.

Control XML Serialization in the Oxygen XML Author Component

Question

How can I force the Oxygen XML Author Component to save the XML with zero indent size and not to break the line inside *block elements*?

Answer

Usually, in a standalone version of Oxygen XML Editor, the **Editor** > **Format** and **Editor** > **Format** > **XML** preferences pages allow you to control the way the XML is saved on the disk after you edit it in the **Author** mode.

In the editor application (Standalone or Eclipse-based), you can either bundle a *default set of options* or use the `PluginWorkspace.setGlobalObjectProperty(String, Object)` API:

```
//For not breaking the line
//Long line
pluginWorkspace.setObjectProperty("editor.line.width", new Integer(100000));
//Do not break before inline elements
pluginWorkspace.setObjectProperty("editor.format.indent.inline.elements", false)
;

//For forcing zero indent
//Force indent settings to be controlled by us
pluginWorkspace.setObjectProperty("editor.detect.indent.on.open", false);
//Zero indent size
pluginWorkspace.setObjectProperty("editor.indent.size.v9.2", 0);
```

In the Oxygen XML Author Component, you can either bundle a *fixed set of options*, or use our Java API to set properties that overwrite the default options:

```
    //For not breaking the line
    //Long line
    AuthorComponentFactory.getInstance().setObjectProperty
("editor.line.width", new Integer(100000));
    //Do not break before inline elements
    AuthorComponentFactory.getInstance().setObjectProperty
("editor.format.indent.inline.elements", false);

    //For forcing zero indent
    //Force indent settings to be controlled by us
    AuthorComponentFactory.getInstance().setObjectProperty
("editor.detect.indent.on.open", false);
    //Zero indent size
    AuthorComponentFactory.getInstance().setObjectProperty
("editor.indent.size.v9.2", 0);
```

Customize the Default Icons for Toolbars/Menus

Question

How can we change the default icons used for the application built-in actions?

Answer

If you look inside the main *JAR* library *[OXYGEN_INSTALL_DIR]*`\lib\oxygen.jar` or *[OXYGEN_INSTALL_DIR]*`\lib\author.jar`, it contains an `images` folder that contains all the images that we use for our buttons, menus, and toolbars.

To overwrite them with your own creations, follow these steps:

1. In the *[OXYGEN_INSTALL_DIR]*`\lib` directory create a folder called `endorsed`.
2. In the `endorsed` folder create another folder called `images`.
3. Add your own images in the `images` folder.

You can use this mechanism to overwrite any kind of resource located in the main *Oxygen JAR library*. The folder structure in the endorsed directory and in the main *Oxygen JAR* must be identical.

Customize the Outline View in Text Mode?

Question

How do I customize the ***Outline*** *view* in **Text** mode?

Answer

Suppose that you have the following XML document:

```
<doc startnumber="15">
```

```
    <sec counter="no">
        <info/>
        <title>Introduction</title>
      </sec>
    <sec>
        <title>Section title</title>
      <para>Content</para>
        <sec>
            <title>Section title</title>
                <para>Content</para>
        </sec>
    </sec>
    <sec>
            <title>Section title</title>
        <para>Content</para>
      </sec>
</doc>
```

and you want to display the XML content in a simplified Outline view like this:

```
doc "15"
sec Introduction
sec 15 Section title
sec 15.1 Section title
sec 16 Section title
```

Usually an Outline should have the following characteristics:

1. Double clicking in the Outline the corresponding XML content would get selected.
2. When the cursor moves in the opened XML document the Outline would select the proper entry.
3. When modifications occur in the document, the Outline would refresh.

A simple implementation using a Workspace Access plugin type could be something like this:

```
/**
 * Simple Outline for Text mode based on executing XPaths over the text content.
 */
 public class CustomWorkspaceAccessPluginExtension implements
WorkspaceAccessPluginExtension {
  /**
   * The custom outline list.
   */
  private JList customOutlineList;

  /**
   * Maps outline nodes to ranges in document
   */
  private WSXMLTextNodeRange[] currentOutlineRanges;

  /**
   * The current text page
   */
  private WSXMLTextEditorPage currentTextPage;

  /**
   * Disable CaretListener when we select from the CaretListener.
   */
  private boolean enableCaretListener = true;

  /**
   * @see WorkspaceAccessPluginExtension#applicationStarted
(ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace)
   */
  @Override
  public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
    pluginWorkspaceAccess.addViewComponentCustomizer
(new ViewComponentCustomizer() {
      /**
       * @see ViewComponentCustomizer#customizeView
(ro.sync.exml.workspace.api.standalone.ViewInfo)
       */
      @Override
      public void customizeView(ViewInfo viewInfo) {
        if(
            //The view ID defined in the "plugin.xml"
            "SampleWorkspaceAccessID".equals(viewInfo.getViewID())) {
          customOutlineList = new JList();
          //Render the content in the Outline.
          customOutlineList.setCellRenderer(new DefaultListCellRenderer() {
       /**
        * @see javax.swing.DefaultListCellRenderer#getListCellRendererComponent
(javax.swing.JList, java.lang.Object, int, boolean, boolean)
        */
      @Override
      public Component getListCellRendererComponent
(JList<?> list, Object value, int index,
          boolean isSelected, boolean cellHasFocus) {
        JLabel label = (JLabel) super.getListCellRendererComponent
```

```
(list, value, index, isSelected, cellHasFocus);
        String val = null;
        if(value instanceof Element) {
          Element element = ((Element)value);
          val = element.getNodeName();
          if(!"".equals(element.getAttribute("startnumber"))) {
            val += " " + "'" + element.getAttribute("startnumber") + "'";
          }
          NodeList titles = element.getElementsByTagName("title");
          if(titles.getLength() > 0) {
            val += " \"" + titles.item(0).getTextContent() + "\"";
         }
       }
        label.setText(val);
        return label;
      }
    });
    //When we click a node, select it in the text page.
    customOutlineList.addMouseListener(new MouseAdapter() {
     @Override
     public void mouseClicked(MouseEvent e) {
       if(SwingUtilities.isLeftMouseButton(e) && e.getClickCount() == 2) {
          int sel = customOutlineList.getSelectedIndex();
          enableCaretListener = false;
         try {
          currentTextPage.select(currentTextPage.getOffsetOfLineStart
(currentOutlineRanges[sel].getStartLine()) +
currentOutlineRanges[sel].getStartColumn() - 1,
            currentTextPage.getOffsetOfLineStart
(currentOutlineRanges[sel].getEndLine()) +
currentOutlineRanges[sel].getEndColumn());
          } catch (BadLocationException e1) {
           e1.printStackTrace();
         }
          enableCaretListener = true;
        }
      }
    });
     viewInfo.setComponent(new JScrollPane(customOutlineList));
     viewInfo.setTitle("Custom Outline");
  }
 }
});

pluginWorkspaceAccess.addEditorChangeListener(new WSEditorChangeListener() {
  /**
  * @see WSEditorChangeListener#editorOpened(java.net.URL)
  */
  @Override
  public void editorOpened(URL editorLocation) {
   //An editor was opened
   WSEditor editorAccess = pluginWorkspaceAccess.getEditorAccess
(editorLocation, StandalonePluginWorkspace.MAIN_EDITING_AREA);
        if(editorAccess != null) {
          WSEditorPage currentPage = editorAccess.getCurrentPage();
          if(currentPage instanceof WSXMLTextEditorPage) {
            //User editing in Text mode an opened XML document.
            final WSXMLTextEditorPage xmlTP = (WSXMLTextEditorPage) currentPage;
            //Reconfigure outline on each change.
            xmlTP.getDocument().addDocumentListener(new DocumentListener() {
              @Override
              public void removeUpdate(DocumentEvent e) {
                reconfigureOutline(xmlTP);
              }
              @Override
              public void insertUpdate(DocumentEvent e) {
                reconfigureOutline(xmlTP);
              }
              @Override
              public void changedUpdate(DocumentEvent e) {
                reconfigureOutline(xmlTP);
              }
            });
            JTextArea textComponent = (JTextArea) xmlTP.getTextComponent();
            textComponent.addCaretListener(new CaretListener() {
              @Override
              public void caretUpdate(CaretEvent e) {
              if(currentOutlineRanges != null && currentTextPage != null &&
enableCaretListener) {
                  enableCaretListener = false;
                  //Find the node to select in the outline.
                  try {
                    int line = xmlTP.getLineOfOffset(e.getDot());
                    for (int i = currentOutlineRanges.length - 1; i >= 0; i--) {
              if(line > currentOutlineRanges[i].getStartLine() &&
line < currentOutlineRanges[i].getEndLine()) {
                       customOutlineList.setSelectedIndex(i);
                       break;
                     }
                    }
                  } catch (BadLocationException e1) {
                    e1.printStackTrace();
                  }
                  enableCaretListener = true;
                }
```

```
              }
            });
          }
        }
      }
      /**
       * @see WSEditorChangeListener#editorActivated(java.net.URL)
       */

   */
  @Override
  public boolean applicationClosing() {
    return true;
  }
}
```

Difference Between a Framework (Document Type) and a Plugin Extension

Question

What is the difference between a *Framework* and a *Plugin* Extension?

Answer

Two ways of customizing the application are possible:

1. Implement a *plugin*.

   A *plugin* serves a general purpose and influences any type of XML file that you open in Oxygen XML Editor.

   For the Oxygen XML Editor Plugins API, Javadoc, samples, and documentation, go to *https://www.oxygenxml.com/oxygen_sdk.html#Developer_Plugins*
2. *Create or modify the document type* that is associated to your specific XML vocabulary.

   This document type can be used, for instance, to provide custom actions for your type of XML files and to mount them on the toolbar, menus, and contextual menus.

   For example, if the end users are editing DITA documents, all the toolbar actions that are specific for DITA are provided by the DITA *framework*. If you look in the ***Document Type Association*** *preferences page* there is a *DITA* document type. If you edit that document type you will see that it has an **Author** tab in the ***Document***

***Type Configuration** dialog box*. The subtabs in this tab can be used to define custom DITA actions and add them to the toolbars, main menus, or contextual menus.

For information about developing your own document types (*frameworks*), see the *Advanced Framework Customization* on page 1385 section.

If you look on disk in the *[OXYGEN_INSTALL_DIR]*`\frameworks\dita` folder, there is a file called `dita.framework`. That file gets updated when you edit a document type from the ***Document Type Association** preferences page*. Then you can share that updated file with all users.

The same folder contains some *JAR* libraries. These libraries contain custom Java operations that are called when the user presses certain toolbar actions.

We have an *Oxygen SDK* that contains the Java sources from all the DITA Java customizations:

https://www.oxygenxml.com/oxygen_sdk.html#XML_Editor_Authoring_SDK

Important: It is possible for a *plugin* to share the same classes with a *framework*. For further details, go to *How to Share the Classloader Between a Framework and a Plugin*.

Add a Custom Operation to an Existing Framework on page 1412

Disable Context-Sensitive Menu Items for Custom Author Actions

Question

Is there a way to disable menu items for custom **Author** mode actions depending on the cursor context?

Answer

By default, Oxygen XML Editor does not toggle the enabled/disabled states for actions based on whether or not the activation XPath expressions for that certain **Author** mode action are fulfilled. This is done because the actions can be many and evaluating XPath expression on each cursor move can lead to performance problems. However, if you have your own *ro.sync.ecss.extensions.api.ExtensionsBundle* implementation you can overwrite the method:

`ro.sync.ecss.extensions.api.ExtensionsBundle.createAuthorExtensionStateListener()`

and when the extension state listener gets activated, you can use the API like this:

```
    /**
     * @see ro.sync.ecss.extensions.api.AuthorExtensionStateListener#activated
(ro.sync.ecss.extensions.api.AuthorAccess)
     */
    public void activated(final AuthorAccess authorAccess) {

      //Add a caret listener to enable/disable extension actions:
authorAccess.getEditorAccess().addAuthorCaretListener(new AuthorCaretListener()
{
    @Override
    public void caretMoved(AuthorCaretEvent caretEvent) {
      try {
        Map<String, Object> authorExtensionActions =
authorAccess.getEditorAccess().getActionsProvider().getAuthorExtensionActions();
        //Get the action used to insert a paragraph. It's ID is "paragraph"
        AbstractAction insertParagraph = (
AbstractAction) authorExtensionActions.get("paragraph");
        //Evaluate an XPath expression in context of the current node
     Object[] evaluateXPath = authorAccess.getDocumentController().evaluateXPath
(".[ancestor-or-self::p]", false, false, false, false);
        if(evaluateXPath != null && evaluateXPath.length > 0 &&
evaluateXPath[0] != null) {
          //We are inside a paragraph, disable the action.
          insertParagraph.setEnabled(false);
        } else {
          //Enable the action
          insertParagraph.setEnabled(true);
        }
      } catch (AuthorOperationException e) {
        e.printStackTrace();
      }
    }
  });
```

When the extension is deactivated, you should remove the *CaretListener* to avoid adding multiple listeners that perform the same functionality.

Dynamically Add Form Controls Using a Styles Filter

Question

How do I add form controls using an API?

Answer

Usually, a form control is added from the CSS using one of the *built-in form controls*. However, in some cases you do not have all the information you need to properly initialize the form control at CSS level. In these cases you can add the form controls by using the API, more specifically *ro.sync.ecss.extensions.api.StylesFilter*.

For instance, if you want a combo box form control and the values to populate the combo are specified inside a file (or they come from a database). Here is how to add the form control from the API:

```
public class SDFStylesFilter implements StylesFilter {

 public Styles filter(Styles styles, AuthorNode authorNode) {
  if(authorNode.getType() == AuthorNode.NODE_TYPE_PSEUDO_ELEMENT
      && "before".equals(authorNode.getName())) {
    authorNode = authorNode.getParent();
   if ("country".equals(authorNode.getName())) {
    // This is the BEFORE pseudo element of the "country" element.
    // Read the supported countries from the configuration file.
    Map<String, Object> formControlArgs = new HashMap<String, Object>();
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_EDIT, "#text");
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_TYPE,
          InplaceEditorArgumentKeys.TYPE_COMBOBOX);
    // This will be a comma separated enumeration: France, Spain, Great Britain
    String countries = readCountriesFromFile();
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_VALUES, countries);
    formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_EDITABLE, "false");

    // We also add a label in form of the form control.
    Map<String, Object> labelProps = new HashMap<String, Object>();
    labelProps.put("text", "Country: ");
    labelProps.put("styles", "* {width: 100px; color: gray;}");
    StaticContent[] mixedContent = new StaticContent[]
           {new LabelContent(labelProps),new EditorContent(formControlArgs)};
    styles.setProperty(Styles.KEY_MIXED_CONTENT, mixedContent);
     }
    }

    // The added form control is the only way the element can be edited.
    if ("country".equals(authorNode.getName())) {
      styles.setProperty(Styles.KEY_VISIBITY, "-oxy-collapse-text");
    }

    return styles;
  }
}
```

If the execution of the `formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_VALUES, countries);` line consumes too much execution time (for example, if it connects to a database or if it needs to extract data from a very large file), you can choose to delay it until the values are actually needed by the form control. This approach is called *lazy evaluation* and can be implemented as follows:

```
formControlArgs.put(InplaceEditorArgumentKeys.PROPERTY_VALUES,
           new LazyValue<List<CIValue>>() {
  public java.util.List<CIValue> get() {
    // We avoid reading the possible values until they are actually requested.
    // This will be a List with CIValues created over countries:
           France, Spain, Great Britain
    return readCountriesFromFile();
  }
});
```

The lazy evaluation approach can be used for the following form controls properties:

- `InplaceEditorArgumentKeys.PROPERTY_VALUES`
- `InplaceEditorArgumentKeys.PROPERTY_LABELS`
- `InplaceEditorArgumentKeys.PROPERTY_TOOLTIPS`

The full source code for this example is available inside the *Oxygen SDK*.

Dynamically Modify the Content Inserted by the Author

Question

Is there a way to insert typographic quotation marks instead of double quotes?

Answer

By using the API you can set a document filter to change the text that is inserted in the document in **Author** mode. You can use this method to change the insertion of double quotes with the typographic quotes.

Here is some sample code:

```
    authorAccess.getDocumentController().setDocumentFilter
(new AuthorDocumentFilter() {
    /**
     * @see ro.sync.ecss.extensions.api.AuthorDocumentFilter#insertText
(ro.sync.ecss.extensions.api.AuthorDocumentFilterBypass, int, java.lang.String)
     */
    @Override
    public void insertText(AuthorDocumentFilterBypass filterBypass,
int offset, String toInsert) {
      if(toInsert.length() == 1 && "\"".equals(toInsert)) {
        //User typed a quote but he actually needs a smart quote.
        //So we either have to add \u201E (start smart quote)
        //Or we add \u201C (end smart quote)
        //Depending on whether there's already a start smart quote inserted
in the current paragraph.

      try {
        AuthorNode currentNode =
authorAccess.getDocumentController().getNodeAtOffset(offset);
        int startofTextInCurrentNode = currentNode.getStartOffset();
        if(offset > startofTextInCurrentNode) {
          Segment seg = new Segment();
        authorAccess.getDocumentController().getChars(startofTextInCurrentNode,
offset - startofTextInCurrentNode, seg);
          String previosTextInNode = seg.toString();
          boolean insertStartQuote = true;
          for (int i = previosTextInNode.length() - 1; i >= 0; i--) {
            char ch = previosTextInNode.charAt(i);
            if('\u201C' == ch) {
              //Found end of smart quote, so yes, we should insert a start one
              break;
            } else if('\u201E' == ch) {
              //Found start quote, so we should insert an end one.
              insertStartQuote = false;
              break;
            }
          }

          if(insertStartQuote) {
            toInsert = "\u201E";
          } else {
            toInsert = "\u201C";
          }
        }
      } catch (BadLocationException e) {
        e.printStackTrace();
      }
    }
    System.err.println("INSERT TEXT |" + toInsert + "|");
    super.insertText(filterBypass, offset, toInsert);
  }
});
```

You can find the online Javadoc for `AuthorDocumentFilter` API here: *https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/AuthorDocumentFilter.html*

An alternative to using a document filtering is the use of a *ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandlerAdapter*, which has clear callbacks indicating the source from where the API is called (Paste, Drag and Drop, Typing).

Dynamically Open File in Oxygen XML Editor Distributed via JavaWebStart

Question

How can we dynamically open a file in an Oxygen XML Editor distributed via JWS?

Answer

The JWS packager Ant build file that is included with Oxygen XML Editor signs by default the JNLP file (this means that a copy of it is included in the main *JAR* library) in this step:

```
<copy file="${outputDir}/${packageName}/${productName}.jnlp" tofile="${home}/JNLP-INF/APPLICATION.JNLP"/>
```

Signing the JNLP file is required by newer Java versions and means that it is impossible to automatically generate a JNLP file containing some dynamic arguments. The solution is to use the signed JNLP template feature of Java 7, bundle inside the *JAR* library a signed `APPLICATION_TEMPLATE.JNLP` instead of an `APPLICATION.JNLP` with a wildcard command line argument:

```
<application-desc main-class="ro.sync.jws.JwsDeployer">
   <argument>*</argument>
</application-desc>
```

Then you can replace the wildcard in the external placed JNLP to the actual, dynamic command line arguments value.

A different, more complicated approach would be to have the JNLP file signed and always referenced as a URL argument a location like this:

```
http://path/to/server/redirectEditedURL.php
```

When the URL gets clicked on the client side you would also call a PHP script on the server side that would update the redirect location for `redirectEditedURL.php` to point to the clicked XML resource. Then the opened Oxygen XML Editor would try to connect to the redirect PHP and be redirected to open the XML.

Extend the Java Functionality of an Existing Framework (Document Type)

Question

How can I change the way a DocBook 4 `xref` displays in **Author** mode based on what element is at the `linkend`?

Answer

Follow these steps:

1. Create a Maven Java project and add a dependency on the Oxygen XML Editor classes:

   ```
   <dependency>
       <groupId>com.oxygenxml</groupId>
       <artifactId>oxygen-sdk</artifactId>
       <version>${oxygen.version}</version>
   </dependency>
   ```

   where `${oxygen.version}` is the version of Oxygen XML Editor.

   Alternatively, if the project does not use Maven, all the transitive dependencies of the above Maven artifact need to be added to the classpath of the project.
2. Also add the *`[OXYGEN_INSTALL_DIR]`*`\frameworks\docbook\docbook.jar` to the class path of the project.
3. Create a class that extends *ro.sync.ecss.extensions.docbook.DocBook4ExtensionsBundle* and overwrites the method: *ro.sync.ecss.extensions.api.ExtensionsBundle#createLinkTextResolver()*
4. For your custom resolver implementation you can start from the Java sources of the *ro.sync.ecss.extensions.docbook.link.DocbookLinkTextResolver* (the Java code for the entire DocBook customization is present in a subfolder in the *Oxygen SDK*).
5. Pack your extension classes in a *JAR* file. Copy the *JAR* to: *`[OXYGEN_INSTALL_DIR]`*`\frameworks\docbook\custom.jar`.
6. Start Oxygen XML Editor.
7. *Open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Document Type Association**. Edit the DocBook 4 document type. In the **Classpath** list add the path to the new *JAR*. In the extensions list select your custom extension instead of the regular DocBook one.

8. You can rename the document type and the `docbook` *framework* folder to something else (such as `custom_docbook`) and share it with others. A document type can also be installed using our *add-on support*.

Impose Custom Options for Authors

Question

How to enable *Track Changes* at startup?

Answer

There are two ways to enable *Track Changes* for every document that you open:

1. You could *customize the default options* that are used by your authors and set the ***Track Changes - Initial State option*** to **Always On**.
2. Use an API to toggle the *Track Changes* state after a document is opened in **Author** mode:

```
// Check the current state of Track Changes
boolean trackChangesOn = authorAccess.getReviewController().isTrackingChanges();
if (!trackChangesOn) {
  // Set Track Changes state to On
  authorAccess.getReviewController().toggleTrackChanges();
}
```

Insert an Element with all the Required Content

Question

I am inserting a DITA `image` XML element using the API that points to a certain resource and has required content. Can the required content be automatically inserted by the application?

Answer

The API *`ro.sync.ecss.extensions.api.AuthorSchemaManager`* can propose valid elements that can be inserted at the specific offset. Using the method `AuthorSchemaManager.createAuthorDocumentFragment(CIElement)`, you can convert the proposed elements to *document fragments* (which have all the required content filled in) that can then be inserted in the document.

```
    AuthorSchemaManager schemaManager =
this.authorAccess.getDocumentController().getAuthorSchemaManager();

    WhatElementsCanGoHereContext context =
schemaManager.createWhatElementsCanGoHereContext
(this.authorAccess.getEditorAccess().getCaretOffset());

    List<CIElement> possibleElementsAtCaretPosition =
schemaManager.whatElementsCanGoHere(context);
    loop: for (int i = 0; i < possibleElementsAtCaretPosition.size(); i++) {
      CIElement possibleElement = possibleElementsAtCaretPosition.get(i);
      List<CIAttribute> attrs = possibleElement.getAttributes();
      if(attrs != null) {
        for (int j = 0; j < attrs.size(); j++) {
          CIAttribute ciAttribute = attrs.get(j);
          if (ciAttribute.getName().equals("class")) {
            if (ciAttribute.getDefaultValue() != null
                && ciAttribute.getDefaultValue().contains("  topic/image ")) {
              //Found a CIElement for image
   //Create a fragment that contains all required child elements already built.
              AuthorDocumentFragment frag =
schemaManager.createAuthorDocumentFragment(possibleElement);
              //Now set the @href to it.
              //Ask the user and obtain a value for the @href
              //Then:

          String href = "test.png";
          List<AuthorNode> nodes = frag.getContentNodes();
          if(!nodes.isEmpty()) {
            AuthorElement imageEl = (AuthorElement) nodes.get(0);
            imageEl.setAttribute("href", new AttrValue(href));
          }
          //And insert the fragment.
          this.authorAccess.getDocumentController().insertFragment
(this.authorAccess.getEditorAccess().getCaretOffset(), frag);
          break loop;
        }
```

```
      }
    }
  }
}
```

AuthorDocumentFragment Class

Modify the XML Content on Open

Question

I have a bunch of DITA documents that have a fixed path the image `src` attributes. These paths are not valid and I am trying to move away from this practice by converting it in to relative paths. When an XML document is opened, can I trigger the Java API to change the fixed path to a relative path?

Answer

The Plugins SDK: *https://www.oxygenxml.com/oxygen_sdk.html#Developer_Plugins* contains a sample plugin type called **WorkspaceAccess**. Such a plugin is notified when the application starts and it can do what you want in a couple of ways:

1. Add a listener that notifies you when the user opens an XML document. Then if the XML document is opened in the **Author** visual editing mode you can use our *Author API* to change attributes:

```
   pluginWorkspaceAccess.addEditorChangeListener(new  WSEditorChangeListener() {
      /**
       * @see WSEditorChangeListener#editorOpened(java.net.URL)
       */
      @Override
      public void editorOpened(URL editorLocation) {
        WSEditor openedEditor = pluginWorkspaceAccess.getCurrentEditorAccess
(StandalonePluginWorkspace.MAIN_EDITING_AREA);
        if(openedEditor.getCurrentPage() instanceof WSAuthorEditorPage) {
        WSAuthorEditorPage authPage = (WSAuthorEditorPage)
openedEditor.getCurrentPage();
        AuthorDocumentController docController =
authPage.getDocumentController();
        try {
         //All changes will be undone by pressing Undo once.
         docController.beginCompoundEdit();
         fixupImageRefs(docController,
          docController.getAuthorDocumentNode());
        } finally {
           docController.endCompoundEdit();
         }
        }
      }

      private void fixupImageRefs
(AuthorDocumentController docController, AuthorNode authorNode) {
          if(authorNode instanceof AuthorParentNode) {
            //Recurse
            List<AuthorNode> contentNodes =
((AuthorParentNode)authorNode).getContentNodes();
            if(contentNodes != null) {
               for (int i = 0; i < contentNodes.size(); i++) {
                 fixupImageRefs(docController, contentNodes.get(i));
               }
             }
          }
          if(authorNode.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
            AuthorElement elem = (AuthorElement) authorNode;
            if("image".equals(elem.getLocalName())) {
               if(elem.getAttribute("href") != null) {
                 String originalHref = elem.getAttribute("href").getValue();
    URL currentLocation = docController.getAuthorDocumentNode().getXMLBaseURL();
                //TODO here you compute the new href.
                String newHref = null;
              docController.setAttribute("href", new AttrValue(newHref), elem);
             }
          }
        }
      }
    },
  StandalonePluginWorkspace.MAIN_EDITING_AREA);
```

2. An API to open XML documents in the application:

```
ro.sync.exml.workspace.api.Workspace.open(URL)
```

So you can create up a plugin that automatically opens one by one XML documents from a certain folder in the application, makes modifications to them, saves the content by calling:

```
ro.sync.exml.workspace.api.editor.WSEditorBase.save()
```

and then closes the editor:

```
ro.sync.exml.workspace.api.Workspace.close(URL)
```

Modify the XML Content on Save

Question

Is it possible to get Oxygen XML Editor to update the revised date on a DITA document when it's saved?

Answer

The Plugins SDK: *https://www.oxygenxml.com/oxygen_sdk.html#Developer_Plugins* contains a sample plugin type called **WorkspaceAccess**.Such a plugin is notified when the application starts.

You can add a listener that notifies you before the user saves an XML document. Then if the XML document is opened in the **Author** visual editing mode you can use our *Author API* to change attributes before the save takes place:

```
      @Override
      public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
       pluginWorkspaceAccess.addEditorChangeListener
(new WSEditorChangeListener(){
         //An editor was opened
        @Override
        public void editorOpened(URL editorLocation) {
          final WSEditor editorAccess = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
          if(editorAccess != null){
            editorAccess.addEditorListener
(new ro.sync.exml.workspace.api.listeners.WSEditorListener(){
              //Editor is about to be saved
              @Override
              public boolean editorAboutToBeSavedVeto(int operationType) {
                if(EditorPageConstants.PAGE_AUTHOR.equals
(editorAccess.getCurrentPageID())){
                  WSAuthorEditorPage authorPage =
(WSAuthorEditorPage) editorAccess.getCurrentPage();
                  AuthorDocumentController controller =
authorPage.getDocumentController();
                  try {
                    //Find the revised element
                    AuthorNode[] nodes = controller.findNodesByXPath
("//revised", true, true, true);
                    if(nodes != null && nodes.length > 0){
                      AuthorElement revised = (AuthorElement) nodes[0];
                      //Set the modified attribute to it...
                      controller.setAttribute("modified",
new AttrValue(new Date().toString()), revised);
                    }
                  } catch (AuthorOperationException e) {
                    e.printStackTrace();
                  }
                }
                //And let the save continue..
                return true;
              }
            });
          }
        }
       }, PluginWorkspace.MAIN_EDITING_AREA);
      }
```

Multiple Rendering Modes for the Same Document in Author Mode

Question

How can we add multiple buttons, each showing a different visualization mode of the same document in **Author** mode?

Answer

In the toolbar of the **Author** mode there is a **Styles** drop-down menu that contains *alternate CSS styles* for the same document. To add an *alternate* CSS stylesheet, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Document Type Association**, select the document type associated with your documents and press **Edit**. In the ***Document Type** configuration dialog box* that appears, go to the **Author** tab, and in the **CSS** subtab add references to *alternate* CSS stylesheets.

For example, one of the alternate CSS stylesheets that we offer for the DITA document type is located here:

```
[OXYGEN_INSTALL_DIR]/frameworks/dita/css_classed/hideColspec.css
```

If you open it, you will see that it imports the *main CSS* and then adds selectors of its own.

Obtain a DOM Element from *AuthorNode* or *AuthorElement*

Question

Can a DOM Element be obtained from an `AuthorNode` or an `AuthorElement`?

Answer

No, a DOM Element cannot be obtained from an `AuthorNode` or an `AuthorElement`. The `AuthorNode` structure is also hierarchical but the difference is that all the text content is kept in a single text buffer instead of having individual text nodes.

We have an image in the Javadoc documentation that explains this situation: *https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/node/AuthorDocumentFragment.html*

Obtain the Currently Selected Element Using the Author API

Question

In **Author** mode, if an element is fully selected, I want to perform an action on it. If not, I want to perform an action on the node that is located at the cursor position. Is this possible via the API?

Answer

When an element is fully selected by the user the selection start and end offsets are actually outside of the node's offset bounds. So using *AuthorDocumentController.getNodeAtOffset* will actually return the parent of the selected node. We have some special API that makes it easier for you to determine this situation: *WSAuthorEditorPageBase.getFullySelectedNode()*.

```
AuthorDocumentController controller = authorPageAccess.getDocumentController();
AuthorAccess authorAccess = authorPageAccess.getAuthorAccess();
int caretOffset = authorAccess.getEditorAccess().getCaretOffset();

    AuthorElement nodeAtCaret =
(AuthorElement) authorAccess.getEditorAccess().getFullySelectedNode();
    if (nodeAtCaret == null) {
     //We have no fully selected node. We can look at the cursor offset.
     nodeAtCaret = (AuthorElement)
authorAccess.getDocumentController().getNodeAtOffset(caretOffset);
    //Or we could look at the selection start and end, see which node is
the parent of each offset and get the closest common ancestor.
}
```

Run XSLT or XQuery Transformations

Question

Can I run XSL 2.0 / 3.0 transformation with Saxon EE using the *Oxygen SDK*?

Answer

The API class *ro.sync.exml.workspace.api.util.XMLUtilAccess* allows you to create an XSLT Transformer that implements the JAXP interface *javax.xml.transform.Transformer*. Then this type of transformer can be used to transform XML. Here's just an example of transforming when you have an *AuthorAccess* API available:

```
     InputSource is = new org.xml.sax.InputSource
(URLUtil.correct(new File("test/personal.xsl")).toString());
     xslSrc = new SAXSource(is);
     javax.xml.transform.Transformer transformer =
authorAccess.getXMLUtilAccess().createXSLTTransformer
(xslSrc, null, AuthorXMLUtilAccess.TRANSFORMER_SAXON_ENTERPRISE_EDITION);
     transformer.transform(new StreamSource(new File("test/personal.xml")),
new StreamResult(new File("test/personal.html")));
```

If you want to create the transformer from the *plugin* side, you can use this method instead: *ro.sync.exml.workspace.api.PluginWorkspace.getXMLUtilAccess()*.

Save a New Document with a Predefined File Name Pattern

Question

Is it possible to get Oxygen XML Editor to automatically generate a file name comprising a UUID plus file extension using the SDK?

Answer

This could be done implementing a *plugin* for Oxygen XML Editor using the Plugins SDK:

https://www.oxygenxml.com/oxygen_sdk.html#Developer_Plugins

There is a type of *plugin* called *Workspace Access* that can be used to add a listener to be notified before an opened editor is saved. The implemented *plugin* would intercept the save events when a newly created document is untitled and display an alternative chooser dialog box, then save the topic with the proper name.

The Java code would look like this:

```
  private static class CustomEdListener extends WSEditorListener{
    private final WSEditor editor;
    private final StandalonePluginWorkspace
        pluginWorkspaceAccess;
    private boolean saving = false;
    public CustomEdListener
(StandalonePluginWorkspace pluginWorkspaceAccess, WSEditor editor) {
            this.pluginWorkspaceAccess = pluginWorkspaceAccess;
            this.editor = editor;
    }
    @Override
    public boolean editorAboutToBeSavedVeto(int operationType) {
      if(! saving &&
        editor.getEditorLocation().toString().contains("Untitled")) {
        File chosenDir = pluginWorkspaceAccess.chooseDirectory();
        if(chosenDir != null) {
          final File chosenFile =
new File(chosenDir, UUID.randomUUID().toString() + ".dita");
        SwingUtilities.invokeLater(new Runnable() {
            @Override
              public void run() {
              try {
                saving = true;
                editor.saveAs(new URL(chosenFile.toURI().toASCIIString()));
              } catch (MalformedURLException e) {
                e.printStackTrace();
              } finally {
                saving = false;
              }
            }
          });
        }

        //Reject the original save request.
        return false;
      }
      return true;
    }
  }

    @Override
    public void applicationStarted
(final StandalonePluginWorkspace pluginWorkspaceAccess) {
    pluginWorkspaceAccess.addEditorChangeListener(new WSEditorChangeListener() {
```

```
      @Override
      public void editorOpened(URL editorLocation) {
        final WSEditor editor = pluginWorkspaceAccess.getEditorAccess
(editorLocation, PluginWorkspace.MAIN_EDITING_AREA);
      if(editor !=
null && editor.getEditorLocation().toString().contains("Untitled")) {

        //Untitled editor
 editor.addEditorListener(new CustomEdListener(pluginWorkspaceAccess, editor));
        }
      }
     },
  PluginWorkspace.MAIN_EDITING_AREA);
.............................................
```

Split Paragraph on Enter (Instead of Showing Content Completion List)

Question

Is it possible to split the paragraph on **Enter** instead of showing the content completion list?

Answer

Yes, it is possible by creating your own custom operation.

To obtain this behavior, follow this procedure:

1. Create a *custom **Author** mode operation* that handles the split. You can use the *`AuthorDocumentController.split` API* to achieve this.
2. Create a JAR library that contains its compiled version.
3. *Open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Document Types Association**, and select your *framework*.
4. Click **Edit** and in the ***Document Type** configuration dialog box*, go to the ***Classpath** tab* and add a reference to the JAR library for your custom operation.
5. Go to the **Author** tab, then go to the **Actions** subtab.
6. Click the **New** button and use the ***Action** dialog box* to create your own paragraph split action.
7. Make sure you assign **Enter** as the **Shortcut Key** and specify your custom operation in the **Operations** section.

Result: Now, when you press **Enter**, your Java operation will be invoked to split the paragraph instead of opening the *Content Completion Assistant*.

Tip: The *Content Completion Assistant* can still be invoked by using the **Ctrl+Space** keyboard shortcut.

Use Custom Rendering Styles for Entity References, Comments, or PIs

Problem

Is there a way to display entity references in the **Author** mode without the distinct gray background and tag markers?

Solution

There is a built-in CSS stylesheet in the Oxygen XML Editor libraries that is used when styling content in the **Author** mode, no matter what CSS you use. This CSS has the following content:

```
@namespace oxy url('http://www.oxygenxml.com/extensions/author');
@namespace xi "http://www.w3.org/2001/XInclude";
@namespace xlink "http://www.w3.org/1999/xlink";
@namespace svg "http://www.w3.org/2000/svg";
@namespace mml "http://www.w3.org/1998/Math/MathML";

oxy|document {
    display:block !important;
}

oxy|cdata {
    display:morph !important;
    white-space:pre-wrap !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 0px !important;
```

```
}

oxy|processing-instruction {
    display:block !important;
    color: rgb(139, 38, 201) !important;
    white-space:pre-wrap !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 0px !important;
}

oxy|comment {
    display:morph !important;
    color: rgb(0, 100, 0) !important;
    background-color:rgb(255, 255, 210) !important;
    white-space:pre-wrap !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 0px !important;
}

oxy|reference:before,
oxy|entity[href]:before{
  link: attr(href) !important;
  text-decoration: underline !important;
  color: navy !important;

  margin: 2px !important;
  padding: 0px !important;
}

oxy|reference:before {
  display: morph !important;
  content: url(../images/editContent.gif) !important;
}

oxy|entity[href]:before{
  display: morph !important;
  content: url(../images/editContent.gif) !important;
}

oxy|reference,
oxy|entity {
    editable:false !important;
    background-color: rgb(240, 240, 240) !important;
    margin:0px !important;
    padding: 0px !important;
}

oxy|reference {
    display:morph !important;
}

oxy|entity {
    display:morph !important;
}

oxy|entity[href] {
  border: 1px solid rgb(175, 175, 175) !important;
  padding: 0.2em !important;
}

xi|include {
    display:block !important;
    margin-bottom: 0.5em !important;
    padding: 2px !important;
}
xi|include:before,
xi|include:after{
    display:inline !important;
    background-color:inherit !important;
    color:#444444 !important;
    font-weight:bold !important;
}

xi|include:before {
    content:url(../images/link.gif) attr(href)  !important;
    link: attr(href) !important;
}
xi|include[xpointer]:before {
    content:url(../images/link.gif) attr(href) " " attr(xpointer) !important;
    link: oxy_concat(attr(href), "#", attr(xpointer)) !important;
}

xi|fallback {
    display:morph !important;
    margin: 2px !important;
    border: 1px solid #CB0039 !important;
}

xi|fallback:before {
    display:morph !important;
    content:"XInclude fallback: " !important;
    color:#CB0039 !important;
}
```

```
oxy|doctype {
    display:block !important;
    background-color: transparent !important;
    color:blue !important;
    border-width:0px !important;
    margin:0px !important;
    padding: 2px !important;
}

oxy|error {
    display:morph !important;
    editable:false !important;
    white-space:pre !important;
    color: rgb(178, 0, 0) !important;
    font-weight:bold !important;
}

*[xlink|href]:before {
    content:url(../images/link.gif);
    link: attr(xlink|href) !important;
}

/*No direct display of the MathML and SVG images.*/
svg|svg{
 display:inline !important;
    white-space: trim-when-ws-only;
}
svg|svg svg|*{
    display:none !important;
    white-space:normal;
}

mml|math{
 display:inline !important;
    white-space: trim-when-ws-only;
}
mml|math mml|*{
    display:none !important;
    white-space: normal;
}
```

In the CSS used for rendering the XML in **Author** mode, do the following:

1. Import the special **Author** mode namespace.
2. Use a special selector to customize the `entity` node.

Example:

```
@namespace oxy url('http://www.oxygenxml.com/extensions/author');
oxy|entity {
   background-color: inherit !important;
   margin:0px !important;
   padding: 0px !important;
    -oxy-display-tags:none;
}
```

You can overwrite styles in the predefined CSS to customize style comments, processing instructions, and *CData* sections. You can also customize the way `xi:include` elements are rendered.

Using the Oxygen XML SDK

16

Topics:

- *Extending Oxygen XML Editor with Plugins*
- *Oxygen XML Author Component*
- *Oxygen XML Web Author*
- *Feature Matrix*

Oxygen XML Editor has an SDK that can be used as a base to develop *frameworks* and *plugins*. It can be also used to create projects that use the Oxygen XML Author Component or Oxygen XML Web Author. The SDK is a Java library available under the *Oxygen XML SDK licensing terms* and is delivered with a set of examples that demonstrate how to extend Oxygen XML functionality through API calls. The SDK is available on our website at *https://www.oxygenxml.com/oxygen_sdk.html*.

Extending Oxygen XML Editor with Plugins

A *plugin* is a software component that adds extra functionality to the standalone version of the application using a series of application-provided extension points.

This chapter explains how to write and install a *plugin* for the standalone version of Oxygen XML Editor. The *Plugins Development Kit* contains sample *plugins* (source and compiled Java code) and the Javadoc API necessary for developing custom *plugins*.

If you want to customize the Oxygen XML Editor Eclipse plugin you can look at the *Eclipse IDE Integration Sample Project* to see how an Eclipse plugin can interact with the Oxygen XML Editor APIs.

General Configuration of an Oxygen XML Editor Plugin

The Oxygen XML Editor functionality can be extended with *plugins* that implement a clearly specified API. On the Oxygen XML Editor website, there is an *SDK* with sample *plugins* (source and compiled Java code) and the Javadoc API necessary for developing custom *plugins*.

The minimal implementation of a *plugin* must provide:

- A Java class that extends the *ro.sync.exml.plugin.Plugin* class.
- A Java class that implements the *ro.sync.exml.plugin.PluginExtension* interface.
- A *plugin* descriptor file called `plugin.xml`.

A *ro.sync.exml.plugin.PluginDescriptor* object is passed to the constructor of the subclass of the *ro.sync.exml.plugin.Plugin* class. It contains the following data items about the *plugin*:

- basedir (*File* object) - The base directory of the *plugin*.
- description (*String* object) - The description of the *plugin*.
- name (*String* object) - The name of the *plugin*.
- vendor (*String* object) - The vendor name of the *plugin*.
- version (*String* object) - The *plugin* version.
- id (*String* object) - A unique identifier.
- classLoaderType - You can choose between `preferOxygenResources` (default value) and `preferReferencedResources`. When choosing `preferOxygenResources`, the libraries that are referenced in the Oxygen XML Editor `lib` directory will have precedence over those referenced in the `plugin.xml` configuration file, if they have the same package names. When choosing `preferReferencedResources`, the libraries that are referenced in the `plugin.xml` configuration file will

have precedence over those found in the Oxygen XML Editor `lib` directory, if they have the same package names.

The *plugin* descriptor is an XML file that defines how the *plugin* is integrated in Oxygen XML Editor and what libraries are loaded. The structure of the *plugin* descriptor file is fully described in a DTD grammar located in *[OXYGEN_INSTALL_DIR]*`/plugins/plugin.dtd`. Here is a sample *plugin* descriptor used by the *Capitalize Lines* sample *plugin*:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin
    name="Capitalize Lines"
    description="Capitalize the first character on each line"
    version="1.0.0"
    vendor="SyncRO"
    class="ro.sync.sample.plugin.caplines.CapLinesPlugin">
    <runtime>
        <library name="lib/caplines.jar"/>
    </runtime>
    <extension type="selectionProcessor"
    class="ro.sync.sample.plugin.caplines.CapLinesPluginExtension"
            keyboardShortcut="ctrl shift EQUALS"/>
</plugin>
```

If your *plugin* is of the **Selection**, **Document** or **General** types, and thus contributes an action either to the contextual menu or to the main menu of the **Text** editing mode, then you can assign a keyboard shortcut for it. You can use the `keyboardShortcut` attribute for each `extension` element to specify the desired shortcut.

Tip: To compose string representations of the desired shortcut keys you can go to the Oxygen XML Editor **Menu Shortcut Keys** preferences page, press **Edit** on any action, press the desired key sequence and use the representation that appears in the **Edit** dialog box.

Referencing Libraries

To reference libraries, use either of the following elements:

- `<library name="path/libraryName" scope="global"/>` - To point to specific libraries. Notice that the value of `library name` includes the path (relative or absolute) to the library.

  Note: You can use the *${oxygenInstallDir} editor variable* as part of the value of the `name` attribute. You can also use a system variable (`${system(var.name)}`) or environment variable (`${env(VAR_NAME)}`).
- `<librariesFolder name="path/libraryFolderPath" scope="global"/>` - To point to multiple libraries located in the specified folder. Notice that the value of `libraryFolder name` includes the path (relative or absolute) to the library folder.

Both elements support the `scope` attribute that defines the loading priority. It can have one of the following three values:

- **local** - The library is loaded in the *plugin's* own class loader. This is the default behavior.
- **global** - The library is loaded in the main application class loader as the last library in the list (as if it would be present in the application `lib` directory).
- **globalHighPriority** - The library is loaded in the main application class loader as the first library in the list (useful to patch certain resources located in other *JARs* of the application).

Installing an Oxygen XML Editor Plugin

Choose one of the following methods to install a *plugin* in Oxygen XML Editor:

Manual Method

To manually install a *plugin* in Oxygen XML Editor, follow these steps:

1. Go to the Oxygen XML Editor installation directory and locate the `plugins` directory.

   Note: The `plugins` directory contains all the *plugins* available to Oxygen XML Editor.
2. In the `plugins` directory, create a subfolder to store the *plugin* files (for example, *[OXYGEN_INSTALL_DIR]*`/plugins/myPlugin`).

3. In the new folder, place the *plugin* descriptor file (`plugin.xml`), the Java classes of the *plugin*, and the other files that are referenced in the descriptor file.
4. Restart Oxygen XML Editor.

Automatic Method

To install an add-on that is hosted on a remote update site, follow these steps:

1. Go to **Help** > **Install new add-ons**.
2. In the displayed dialog box, enter or paste the update site that hosts the add-on in the **Show add-ons from** field (or select it from the drop-down menu, if applicable). The default add-ons are hosted on **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml**. If you want to see a list of all the default and sample add-ons that are available on the Oxygen remote update sites, choose **ALL AVAILABLE SITES** from the drop-down menu. The add-ons list contains the name, status, update version, Oxygen XML Editor version, and the type of the add-on (either **framework**, or **plugin**). A short description of each add-on is presented under the add-ons list.

   Note: To see all the versions of the add-ons, deselect **Show only compatible add-ons** and **Show only the latest version of the add-ons**. Incompatible add-ons are shown only to acknowledge their presence on the remote update site, but you cannot install an incompatible add-on.
3. Choose the add-ons you want to install, press the **Next** button, then follow the on-screen instructions.

   Note: Accepting the license agreement of the add-on is a mandatory step in the installation process.

   Note: All add-ons are installed in the `extensions` directory inside the Oxygen XML Editor *preferences directory*.

Types of Plugin Extensions Available with the SDK

A *plugin* can have one or more defined *plugin extensions* that provide functionality to the application. This section presents the *plugin extensions* that are available.

Author Stylesheet Plugin Extension

This type of *plugin* allows you to add a stylesheet (CSS or LESS) that renders elements in **Author** mode.

To specify additional stylesheets, edit the *plugin* descriptor and add `extension` elements that point to them, as in the following example:

```
<extension type="AuthorStylesheet" href="showTables.css"/>
<extension type="AuthorStylesheet" href="hideButtons.css"/>
```

Using this mechanism, you can add one or more CSS stylesheets to merge with the existing ones. Whenever you add a new stylesheet using this *plugin*, it will have priority over all other stylesheets applied on the file edited in **Author** mode.

If your implementation requires more flexibility (such as a dynamic change of the stylesheet), you should consider using the *StylesFilter plugin extension*.

Additional Framework Plugin Extension

This type of *plugin* allows you to add a new framework straight from the *plugin*.

To specify additional frameworks, edit the *plugin* descriptor and add `extension` elements that point to them, as in the following example:

```
<extension type="AdditionalFrameworks" path="framework_directory"/>
```

The path attribute should be a sub-directory of the plugin. If the *plugin* is *installed as an add-on*, the new framework will be set as read-only and editing it will only be possible if you *duplicate it*. If the *plugin* is installed in the *[OXYGEN_INSTALL_DIR]*`/plugins` directory, the new frameworks will be editable.

Components Validation Plugin Extension

This type of *plugin* allows you to customize the menus, toolbars, and other components by enabling or filtering them from the user interface.

This *plugin* provides the following API:

- ***ComponentsValidatorPluginExtension* interface** - There is one method that must be implemented:
  - *getComponentsValidator()* - Returns a *ro.sync.exml.ComponentsValidator* implementation class used for validating the menus, toolbars, and their actions.
- ***ComponentsValidator* interface** - Provides methods to filter various features from being added to the GUI of Oxygen XML Editor:
  - *validateMenuOrTaggedAction(String[] menuOrActionPath)* - Checks if a menu or a tag action from a menu is allowed and returns a `boolean` value. A tag is used to uniquely identifying an action. The *String[]* argument is the tag of the menu / action and the tags of its parent menus if any.
  - *validateToolbarTaggedAction(String[] toolbarOrAction)* - Checks if an action from a toolbar is allowed and returns a *boolean* value. The *String[]* argument is the tag of the action from a toolbar and the tag of its parent toolbar if any.
  - *validateComponent(String key)* - Checks if the given component is allowed and returns a `boolean` value. The *String* argument is the tag identifying the component. You can remove toolbars entirely using this callback.
  - *validateAccelAction(String category, String tag)* - Checks if the given accelerator action is allowed to appear in the GUI and returns a `boolean` value. An accelerator action can be uniquely identified so it will be removed both from toolbars or menus. The first argument represents the action category, the second is the tag of the action.
  - *validateContentType(String contentType)* - Checks if the given content type is allowed and returns a `boolean` value. The *String* argument represents the content type. You can instruct Oxygen XML Editor to ignore content types such as `text / xsl` or `text / xquery`.
  - *validateOptionPane(String optionPaneKey)* - Checks if the given options page can be added in the preferences option tree and returns a `boolean` value. The *String* argument is the option pane key.
  - *validateOption(String optionKey)* - Checks if the given option can be added in the option page and returns a `boolean` value. The *String* argument is the option key. This method is mostly used for internal use and it is not called for each option in a preferences page.
  - *validateLibrary(String library)* - Checks if the given library is allowed to appear listed in the **About** dialog box and returns a `boolean` value. The *String* argument is the library. This method is mostly for internal use.
  - *validateNewEditorTemplate(EditorTemplate editorTemplate)* - Checks if the given template for a new editor is allowed and returns a `boolean` value. The *EditorTemplate* argument is the editor template. An *EditorTemplate* is used to create an editor for a given extension. You can thus filter what appears in the list of the **New** dialog box.
  - *isDebuggerperspectiveAllowed()* - Checks if the debugger *perspective* is allowed and returns a `boolean` value.
  - *validateSHMarker(String marker)* - Checks if the given marker is allowed and returns a `boolean` value. The *String* argument represents the syntax highlight marker to be checked. If you decide to filter certain content types, you can also filter the syntax highlight options so that the content type is no longer present in the Preferences options tree.
  - *validateToolbarComposite(String toolbarCompositeTag)* - Checks if the toolbar composite is available. A toolbar composite is a toolbar component such as a drop-down menu.

Tip: The best way to decide what to filter is to observe the values that Oxygen XML Editor passes when these callbacks are called. You have to create an implementation for this interface that lists in the console all values received by each function. Then you can decide on the values to filter and act accordingly.

Custom Protocol Plugin Extension
This type of *plugin* allows you to work with a custom designed protocol for retrieving and storing files.

It provides the following API:

- ***URLStreamHandlerPluginExtension* interface** - There is one method that must be implemented:
  - *getURLStreamHandler(String protocol)* - It takes as an argument the name of the protocol and returns a `URLStreamHandler` object, or null if there is no URL handler for the specified protocol.

This type of *plugin* extension can be usually combined with a *Workspace Access plugin extension* that can add a custom toolbar with custom actions for opening documents from a certain source.

As an alternative, two older *plugin* extensions can also be used to add a toolbar action for showing a custom URL chooser:

- ***URLChooserPluginExtension2* interface** - Makes it possible to create your own dialog box that works with the custom protocol. This interface provides two methods:
  - *chooseURLs(StandalonePluginWorkspace workspaceAccess)* - Returns a URL [ ] object that contains the URLs the user decided to open with the custom protocol. You can invoke your own URL chooser dialog box here and then return the chosen URLs having your own custom protocol. You have access to the workspace of Oxygen XML Editor.
  - *getMenuName()* - Returns a `String` object that is the name of the entry added in the **File** menu.
- ***URLChooserToolbarExtension* interface** - Makes it possible to provide a toolbar entry that is used for launching the custom URLs chooser from the *URLChooserPluginExtension* implementation. This interface provides two methods:
  - *getToolbarIcon()* - Returns the `javax.swing.Icon` image used on the toolbar.
  - *getToolbarTooltip()* - Returns a `String` that is the tooltip used on the toolbar button.

Lock Handler Plugin Extension
This type of *plugin extension* is used for locking resources from a specific protocol.

It provides the following API:

- ***LockHandlerFactoryPluginExtension* interface**:

  You need to implement the following two methods:

  - *LockHandler getLockHandler()*

    Gets the lock handler for the current handled protocol. Might be `null` if not supported.
  - *boolean isLockingSupported(String protocol)*

    Checks if a lock handler can be provided for a specific protocol.

  To use this type of extension in your *plugin*, create an extension of *LockHandlerFactory* type in your `plugin.xml` file and specify the class implementing *LockHandlerFactoryPluginExtension*:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin name="CustomLockHandler" ..............>
 <runtime>
  ........
 </runtime>

 <extension type="LockHandlerFactory"
        class="LockHandlerFactoryPluginExtensionImpl"/>
 ...............

</plugin>
```

Open Redirect Plugin Extension
This type of *plugin* is useful for opening multiple files with only one open action.

For example, when a zip archive or an ODF file or an OOXML file is open in the ***Archive Browser** view* a *plugin* of this type can decide to open a file also from the archive in an XML editor panel. This file can be the `document.xml` main file from an OOXML file archive or a specific XML file from a zip archive.

The *plugin* must implement the interface *OpenRedirectExtension*. It only has one callback: `redirect(URL)` that receives the URL of the file opened by the Oxygen XML Editor user. If the *plugin* decides to open also other files it must return an array of information objects (*OpenRedirectInformation[]*) that correspond to these files. Such an information object must contain the URL that is opened in a new editor panel and the content type (for example, `text/xml`). The content type is used for determining the type of editor panel. A `null` content type allows auto-detection of the file type.

Option Page Plugin Extension
This type of *plugin extension* allows you to add custom **Preferences** pages.

The extension must implement the *ro.sync.exml.plugin.option.OptionPagePluginExtension* interface. The provided callbacks allow you to create a custom *Swing* component that will be added to the page and to react to various calls to persistently save the page settings using the `OptionsStorage` API.

All preferences pages that are contributed by a *plugin* are listed in the **Preferences** dialog box in the **Plugins** category. As long as the added preferences page has the same name as its *plugin*, it will be promoted to the first level of the hierarchy within the **Plugins** category.

The `plugin.xml` configuration file can specify one or more such extensions using constructs like this:

```
<extension type="OptionPage" class="my.pack.CustomOptionPagePluginExtension"/>
```

Resource Locking Custom Protocol Plugin Extension
This type of *plugin* allows you to work with a custom designed protocol for retrieving and storing files and it can lock a resource when opening it in Oxygen XML Editor.

This type of *plugin* extends the custom protocol *plugin* type with resource locking support and provides the following API:

- ***URLStreamHandlerWithLockPluginExtension* interface** - The *plugin* receives callbacks following the simple protocol for resource locking and unlocking imposed by Oxygen XML Editor.

  There are two additional methods that must be implemented:

  - **getLockHandler()** - Returns a `LockHandler` implementation class with the implementation of the lock specific methods from the *plugin*.
  - **isLockingSupported(String protocol)** - Returns a `boolean` that is `true` if the *plugin* accepts to manage locking for a certain URL protocol scheme (such as `ftp`, `http`, `https`, or `customName`).

Styles Filter Plugin Extension
This type of *plugin* allows you to dynamically modify the CSS styles used to render elements in the **Author** mode.

The *plugin* must extend the *ro.sync.exml.plugin.author.css.filter.GeneralStylesFilterExtension* class. This class has a callback on which you can alter the styles for an **Author** mode element.

This extension point is similar with the Styles Filter that you set at the *framework* level. The only difference is that the *plugin* filters styles are used for any opened XML document, regardless of the document type. The changes made by this *plugin* are prioritized over the changes made by the *framework*-level filter.

Note: Alternatively, you can use the *AuthorStylesheet plugin extension*, which does not require any additional Java development and is compatible with Oxygen XML Web Author.

Related Information:
Configuring CSS Styles Filter on page 1445

Targeted URL Stream Handler Plugin Extension
This type of *plugin* can be used when it is necessary to impose custom URL stream handlers for specific URLs.

This *plugin* extension can handle the following protocols: `http`, `https`, `ftp` or `sftp`, for which Oxygen XML Editor usually provides specific fixed URL stream handlers. If it is set to handle connections for a specific protocol, this extension will be asked to provide the URL stream handler for each opened connection of a URL having that protocol.

To use this type of *plugin*, you have to implement the *ro.sync.exml.plugin.urlstreamhandler.TargetedURLStreamHandlerPluginExtension* interface, that provides the following methods:

- ***boolean canHandleProtocol(String protocol)*** - This method checks if the *plugin* can handle a specific protocol. If this method returns `true` for a specific protocol, the *getURLStreamHandler(URL)* method will be called for each opened connection of a URL having this protocol.
- ***URLStreamHandler getURLStreamHandler(URL url)*** - This method provides the URL handler for the specified URL and it is called for each opened connection of a URL with a protocol for which the *canHandleProtocol(String)* method returns `true`.

  If this method returns `null`, the default Oxygen XML Editor *URLStreamHandler* is used.

To use this type of extension in your *plugin*, create an extension of *TargetedURLHandler* type in your `plugin.xml` file and specify the class that implements *TargetedURLStreamHandlerPluginExtension*:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin name="CustomTargetedURLStreamHandlerPlugin" ..............>
 <runtime>
  ........
 </runtime>

 <extension type="TargetedURLHandler"
          class="CustomTargetedURLStreamHandlerPluginExtension"/>
 ...............

</plugin>
```

This extension can be useful in situations when connections opened from a specific host must be handled in a particular way. For example, the Oxygen XML Editor *HTTP URLStreamHandler* may not be compatible for sending and receiving SOAP using the SUN Web Services implementation. In this case, you can override the stream handler (set by Oxygen XML Editor) to use the default SUN *URLStreamHandler*, since it is more compatible with sending and receiving SOAP requests.

```
public class CustomTargetedURLStreamHandlerPluginExtension
  implements TargetedURLStreamHandlerPluginExtension {

  @Override
  public boolean canHandleProtocol(String protocol) {
    boolean handleProtocol = false;
    if ("http".equals(protocol) || "https".equals(protocol)) {
      // This extension handles both HTTP and HTTPS protocols
      handleProtocol = true;
    }
    return handleProtocol;
  }

  @Override
  public URLStreamHandler getURLStreamHandler(URL url) {
    // This method is called only for the URLs with a protocol
    // where canHandleProtocol(String) method returns true (HTTP and HTTPS)

    URLStreamHandler handler = null;

    String host = url.getHost();
    String protocol = url.getProtocol();
    if ("some_host".equals(host)) {
      // When there are connections opened from some_host, the SUN HTTP(S)
      // handlers are used
      if ("http".equals(protocol)) {
        handler = new sun.net.www.protocol.http.Handler();
      } else {
        handler = new sun.net.www.protocol.https.Handler();
      }
    }
    return handler;
  }
}
```

Workspace Access Plugin Extension

This type of *plugin* allows you to contribute actions to the main menu and toolbars, create custom views, interact with the application workspace, make modifications to opened documents, and add listeners for various events.

Many complex integrations (such as integrations with Content Management Systems) usually requires access to some workspace resources such as toolbars, menus, views, and editors. This type of *plugin* is also useful because it allows you to make modifications to the XML content of an opened editor.

The *plugin* must implement the *ro.sync.exml.plugin.workspace.WorkspaceAccessPluginExtension* interface. The callback method *applicationStarted* of this interface allows access to a parameter of the *ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace* type (allows for API access to the application workspace).

The *StandalonePluginWorkspace* interface has three methods that can be called to customize toolbars, menus, and views:

- ***addToolbarComponentsCustomizer*** - Contributes to or modifies existing toolbars. You can specify additional toolbar IDs in the associated `plugin.xml` descriptor file using the following construct:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <!DOCTYPE plugin SYSTEM "../plugin.dtd">
  ```

```
<plugin name="CustomWorkspaceAccess" ..............>
 <runtime>
  ........
 </runtime>

 <extension type="WorkspaceAccess" ............../>
 ..............
  <toolbar id="SampleID" initialSide="NORTH" initialRow="1"/>
</plugin>
```

The `toolbar` element adds a toolbar in the Oxygen XML Editor interface and allows you to contribute your own *plugin*-specific actions. The following attributes are supported:

- `id` - Unique identifier for the toolbar.
- `initialSide` - Specifies the place where the toolbar is initially displayed. The allowed values are `NORTH` and `SOUTH`.
- `initialRow` - Specifies the initial row on the specified side where the toolbar is displayed. For example, the first toolbar has an initial row of `0` and the next toolbar has an initial row of `1`.

The *ro.sync.exml.workspace.api.standalone.ToolbarInfo* toolbar component information with the specified ID will be provided to you by the customizer interface. Therefore, you will be able to provide Swing components that will appear on the toolbar when the application starts.

- ***addViewComponentCustomizer*** - Contributes to or modifies existing views, or contributes to the reserved custom view. You can specify additional view IDs in the associated `plugin.xml` descriptor using the following construct:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin name="CustomWorkspaceAccess" ..............>
 <runtime>
  ........
 </runtime>

 <extension type="WorkspaceAccess" ............../>
 ..............
 <view id="SampleID" initialSide="WEST" initialRow="0"/>
</plugin>
```

The `view` element adds a view in the Oxygen XML Editor interface and allows you to contribute your own *plugin*-specific UI components. The following attributes are supported:

- `id` - Unique identifier of the view component.
- `initialSide` - Specifies the place where the view is initially displayed. The allowed values are: `NORTH`, `SOUTH`, `EAST`, and `WEST`.
- `initialRow` - Specifies the initial row on the specified side where the view is displayed. For example, in Oxygen XML Editor, the ***Project** view* has an initial row of `0` and the ***Outline** view* has an initial row of `1`. Both views are in the WEST part of the workbench.
- `initialState` - Specifies the initial state of the view. The allows values are: `hidden`, `docked`, `autohide`, and `floating`. By default, the view is visible and docked.

The *ro.sync.exml.workspace.api.standalone.ViewInfo* view component information with the specified ID will be provided to you by the customizer interface. Therefore, you will be able to provide Swing components that will appear on the view when the application starts.

- ***addMenuBarCustomizer*** - Contributes to or modifies existing menu components.

Access to the opened editors can be done by first getting access to all URLs opened in the workspace using the *StandalonePluginWorkspace.getAllEditorLocations(int editingArea)* API method. There are two available editing areas: the **DITA Maps Manager** editing area and the main editing area. Using the URL of an opened resource, you can gain access to it using the *StandalonePluginWorkspace.getEditorAccess(URL location, int editingArea)* API method. A *ro.sync.exml.workspace.api.editor.WSEditor* then allows access to the current editing page.

A special editing API is supported for the **Text** mode (*ro.sync.exml.workspace.api.editor.page.text.WSTextEditorPage*) and the **Author** mode (*ro.sync.exml.workspace.api.editor.page.author.WSAuthorEditorPage*).

To be notified when editors are opened, selected, and closed, you can use the *StandalonePluginWorkspace.addEditorChangeListener* API method to add a listener.

Examples:

- A simple Maven-based sample of a workspace access plugin is available here: *https://github.com/oxygenxml/sample-plugin-workspace-access*
- A more complex sample of a workspace access plugin mimicking a CMS integration is available in the Author SDK: *https://www.oxygenxml.com/oxygen_sdk.html*

Adding a Custom View in Oxygen XML Editor

To add a custom view in Oxygen XML Editor, follow this procedure:

1. Locate the `plugin.xml` descriptor file for your plugin (should be located inside the Oxygen **plugins** folder, for example, *[OXYGEN_INSTALL_DIR]*`/plugins/myPlugin`). Define the ID of the view you want to add and specify the location where it will be placed:

   ```
   <view id="SampleWorkspaceAccessID" initialSide="WEST" initialRow="0"/>
   ```

2. In your *Workspace Access Plugin Extension* on page 1561 implementation, where the `applicationStarted` callback is received, add a view component customizer like this:

   ```
   pluginWorkspaceAccess.addViewComponentCustomizer(new ViewComponentCustomizer() {
    public void customizeView(ViewInfo viewInfo) {
      if(
        //The view ID defined in the "plugin.xml"
        "SampleWorkspaceAccessID".equals(viewInfo.getViewID())) {
        cmsMessagesArea = new JTextArea("CMS Session History:");
        viewInfo.setComponent(new JScrollPane(cmsMessagesArea));
        viewInfo.setTitle("CMS Messages");
        viewInfo.setIcon(Icons.getIcon(Icons.CMS_MESSAGES_CUSTOM_VIEW_STRING));
      }
    }
   });
   ```

3. Define the `cmsMessagesArea` as a *static* field (if you can access the messages area from anywhere in your code).

Related Information:

Workspace Access Plugin Extension (JavaScript-Based)
This is a JavaScript-based *plugin* extension that allows you to contribute actions to the main menu and toolbars, create custom views, interact with the application workspace, make modifications to opened documents, and add listeners for various events.

This extension can use the same API as the *Workspace Access plugin extension*, but the implementation is JavaScript-based and uses the bundled *Rhino* library to create and work with Java API from the JavaScript code.

First, you need to create a custom plugin folder inside the Oxygen **plugins** folder (for example, *[OXYGEN_INSTALL_DIR]*`/plugins/myPlugin`). This folder will contain your custom *plugin* descriptor file (`plugin.xml`) and all other resources for the plugin.

The *plugin* descriptor file (named `plugin.xml`) needs to reference a JavaScript file, as in the following example:

```
<!DOCTYPE plugin PUBLIC "-//Oxygen Plugin" "../plugin.dtd">
<plugin
 id="unique.id.value"
 name="Add Action To DITA Maps Manager popup-menu"
 description="Plugin adds action to DITA Maps Manager contextual menu."
 version="1.0"
 vendor="Syncro Soft"
 class="ro.sync.exml.plugin.Plugin"
 classLoaderType="preferReferencedResources">
 <extension type="WorkspaceAccessJS" href="wsAccess.js"/>
</plugin>
```

In the example above, the JavaScript file `wsAccess.js` (located in *your custom plugin folder*) will be called. This JavaScript file needs to have two JavaScript methods defined inside. Methods that will be called when the application starts and when it ends:

```
function applicationStarted(pluginWorkspaceAccess) {
..........
}

function applicationClosing(pluginWorkspaceAccess) {
..........
}
```

In regards to the `applicationStarted` callback, besides using the *ro.sync.exml.workspace.api.standalone.StandalonePluginWorkspace* API with the `pluginWorkspaceAccesspluginWorkspaceAccess` parameter, you can also use a globally defined field called `jsDirURL` that points to the folder where the JavaScript file is located.

Below is a much larger example with a JavaScript Workspace Access *plugin* extension implementation that adds a new action in the contextual menu of the ***DITA Maps Manager*** *view*. The action starts the `notepad.exe` application and passes the reference to the currently selected `topicref` to it.

```
function applicationStarted(pluginWorkspaceAccess) {
 Packages.java.lang.System.err.println("Application started "
      + pluginWorkspaceAccess);
 edChangedListener = {
  /*Called when a DITA Map is opened*/
   editorOpened: function (editorLocation) {
   Packages.java.lang.System.err.println("\nrunning " + editorLocation);
  /*Get the opened DITA Map*/
   editor = pluginWorkspaceAccess.getEditorAccess(editorLocation,
   Packages.ro.sync.exml.workspace.api.PluginWorkspace.DITA_MAPS_EDITING_AREA);
   ditaMapPage = editor.getCurrentPage();
  /*Add listener called when right-click is done in the DITA Maps manager*/
   customizerObj = {
   customizePopUpMenu: function (popUp, ditaMapDocumentController) {
   Packages.java.lang.System.err.println("RIGHT CLICK" + popUp);
   tree = ditaMapPage.getDITAMapTreeComponent();
  /*Selected tree path*/
   sel = tree.getSelectionPath();
   if (sel != null) {
   selectedElement = sel.getLastPathComponent();
  /*Reference attribute*/
   href = selectedElement.getAttribute("href");
   if (href != null) {
     try {
  /*Create absolute reference*/
   absoluteRef = new Packages.java.net.URL(selectedElement.getXMLBaseURL(),
           href.getValue());
   Packages.java.lang.System.err.println("Computed absolute reference "
         + absoluteRef);
   mi = new Packages.javax.swing.JMenuItem("Run notepad");
        popUp.add(mi);
        actionPerfObj = {
        actionPerformed: function (e) {
          try {
           Packages.java.lang.Runtime.getRuntime().exec("notepad.exe "
               + pluginWorkspaceAccess.getUtilAccess().locateFile(absoluteRef));
          }
        catch (e1) {
         e1.printStackTrace();
          }
         }
        }
   mi.addActionListener(new JavaAdapter(Packages.java.awt.event.ActionListener,
             actionPerfObj));
       }
       catch (e1) {
        Packages.java.lang.System.err.println(e1);
       }
      }
     }
    }
   }

   ditaMapPage.setPopUpMenuCustomizer(new Packages.ro.sync.exml.workspace.api.
editor.page.ditamap.DITAMapPopupMenuCustomizer(customizerObj));
  }
 }
   edChangedListener = new JavaAdapter(Packages.ro.sync.exml.workspace.api.
listeners.WSEditorChangeListener, edChangedListener);
   pluginWorkspaceAccess.addEditorChangeListener(
   edChangedListener,
   Packages.ro.sync.exml.workspace.api.PluginWorkspace.DITA_MAPS_EDITING_AREA);
}

 function applicationClosing(pluginWorkspaceAccess) {
   Packages.java.lang.System.err.println("Application closing "
        + pluginWorkspaceAccess);
}
```

For more information and some samples, see *GitHub Project with Multiple Workspace Access JavaScript-Based Plugin Samples*.

XML Refactoring Operations Plugin Extension

This type of *plugin* allows you to specify one or more directories where the XML Refactoring operation resources are loaded.

The `RefactoringOperationsProvider` extension can be used to specify the location where custom XML Refactoring operation resources (XQuery Update script or XSLT stylesheet and Operation Descriptor files) are stored. Oxygen XML Editor will scan the specified locations to load the custom operations when the XML Refactoring tool is opened, and allows you to share your custom refactoring operations.

Example: XML Refactoring Operations Plugin Extension

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plugin PUBLIC "-//Oxygen Plugin" "../plugin.dtd">

<plugin
 id="refactoring.operations"
 name="Refactoring operations plugin"
 description="Contains operation descriptors and related scripts"
 version="1.0">
 <extension type="RefactoringOperationsProvider">
  <folder path="customDir/"/>
  <folder path="customDir2"/>
 </extension>
</plugin>
```

Plugin Extensions Designed to Work only in the Text Editing Mode

These *plugin* extensions operate only when editing documents in the **Text** mode. They are mounted automatically by the application on the contextual menu in the **Plugins** submenu.

General Plugin Extension
This type of *plugin* allows you to invoke custom code to interact with the workspace in **Text** mode.

This *plugin* is the most general *plugin* type and provides a limited API:

- ***GeneralPluginExtension* interface** - Intended for general-purpose *plugins*, kind of external tools but triggered from the **Plugins** menu. The implementing classes must provide the method *process(GeneralPluginContext)*, which must provide the *plugin* processing. This method takes as a parameter a *GeneralPluginContext* object.
- ***GeneralPluginContext* class** - Represents the context in which the general *plugin* extension does its processing. The *getPluginWorkspace()* method allows you access to the workspace of Oxygen XML Editor.

Selection Plugin Extension
This type of *plugin* allows you to manage selections of text.

A **selection** *plugin* can be applied to both XML and non-XML documents. The *plugin* is started by making a selection in the editor, then selecting the corresponding menu item from the **Plugins** submenu in the contextual menu of **Text** mode.

This *plugin* type provides the following API:

- ***SelectionPluginExtension* interface** - The context containing the selected text is passed to the extension and the processed result is going to replace the initial selection. The *process(GeneralPluginContext)* method must return a *SelectionPluginResult* object that contains the result of the processing. The *String* value returned by the *SelectionPluginResult* object can include *editor variables* such as *${caret}* and *${selection}*.
- ***SelectionPluginContext* object** - Represents the context and provides four methods:
  - **getSelection()** - Returns a `String` that is the current selection of text.
  - **getFrame()** - Returns a `Frame` that is the editing frame.
  - **getPluginWorkspace()** - Returns access to the workspace of Oxygen XML Editor.
  - **getDocumentURL()** - Returns the URL of the current edited document.

Related Information:
Editor Variables on page 173

Example - Uppercase Plugin

The following *plugin* is called **UppercasePlugin** and is an example of a *Selection plugin.*. It is used in Oxygen XML Editor for capitalizing the characters in the current selection. This example consists of two Java classes and the *plugin* descriptor file (`plugin.xml`):

- **UppercasePlugin.java**:

```
package ro.sync.sample.plugin.uppercase;
```

```
import ro.sync.exml.plugin.Plugin;
import ro.sync.exml.plugin.PluginDescriptor;

public class UppercasePlugin extends Plugin {
    /**
    * Plugin instance.
    */
    private static UppercasePlugin instance = null;

    /**
    * UppercasePlugin constructor.
    *
    * @param descriptor Plugin descriptor object.
    */
    public UppercasePlugin(PluginDescriptor descriptor) {
        super(descriptor);

        if (instance != null) {
            throw new IllegalStateException("Already instantiated !");
        }
        instance = this;
    }

    /**
    * Get the plugin instance.
    *
    * @return the shared plugin instance.
    */
    public static UppercasePlugin getInstance() {
        return instance;
    }
}
```

- **UppercasePluginExtension.java**:

```
package ro.sync.sample.plugin.uppercase;

import ro.sync.exml.plugin.selection.SelectionPluginContext;
import ro.sync.exml.plugin.selection.SelectionPluginExtension;
import ro.sync.exml.plugin.selection.SelectionPluginResult;
import ro.sync.exml.plugin.selection.SelectionPluginResultImpl;

public class UppercasePluginExtension implements SelectionPluginExtension {
    /**
    * Convert the text to uppercase.
    *
    *@param  context  Selection context.
    *@return          Uppercase plugin result.
    */
    public SelectionPluginResult process(SelectionPluginContext context) {
        return new SelectionPluginResultImpl(
            context.getSelection().toUpperCase());
    }
}
```

- **plugin.xml**:

```
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin
    name="UpperCase"
    description="Convert the selection to uppercase"
    version="1.0.0"
    vendor="SyncRO"
    class="ro.sync.sample.plugin.uppercase.UppercasePlugin">
    <runtime>
        <library name="lib/uppercase.jar"/>
    </runtime>
    <extension type="selectionProcessor"
     class="ro.sync.sample.plugin.uppercase.UppercasePluginExtension"/>
</plugin>
```

Document Plugin Extension
This type of *plugin* allows you to manage the current document.

The **document** *plugin* type can only be applied to an XML document. It can modify the current document that is received as a callback parameter.

The *plugin* is started by selecting the corresponding menu item from the **Plugins** submenu in the contextual menu of **Text** mode. It provides the following API:

- ***DocumentPluginExtension* interface** - Receives the context object containing the current document. The *process(GeneralPluginContext)* method can return a *DocumentPluginResult* object containing a new document.
- ***DocumentPluginContext* object** - Represents the context and provides three methods:

- **getDocument()** - Returns a `javax.swing.text.Document` object that represents the current document.
- **getFrame()** - Returns a `java.awt.Frame` object that represents the editing frame.
- **getPluginWorkspace()** - Returns access to the workspace of Oxygen XML Editor.

Oxygen XML Editor Plugin How to...

This section includes information about how to implement complex *plugins*.

How to Write a CMS Integration Plugin

To have a complete integration between Oxygen XML Editor and a CMS, you usually have to write a *plugin* that combines the following two available *plugin* extensions:

- *Workspace Access*
- *Custom protocol*

The usual set of requirements for an integration between Oxygen XML Editor and the CMS are as follows:

- Contribute to the Oxygen XML Editor toolbars and main menu with your custom **Check Out** and **Check In** actions:
  - **Check Out** triggers your custom dialog boxes that allow you to browse the remote CMS and choose the resources you want to open.
  - **Check In** allows you to send the modified content back to the server.

    You can use the **Workspace Access** *plugin extension* (and provided sample Java code) for all these operations.
- When **Check Out** is called, use the Oxygen XML Editor API to open your custom URLs (URLs created using your custom protocol). It is important to implement and use a **Custom Protocol** extension to be notified when the files are opened and saved and to be able to provide the content for the relative references the files may contain to Oxygen XML Editor . Your custom *java.net.URLStreamHandler* implementation checks out the resource content from the server, stores it locally and provides its content. Sample **Check Out** implementation:

```
  /**
   * Sample implementation for the "Check Out" method.
   *
   * @param pluginWorkspaceAccess (Workspace Access plugin).
   * @throws MalformedURLException
   */
    private void checkOut(StandalonePluginWorkspace pluginWorkspaceAccess)
throws MalformedURLException {
    //TODO Show the user a custom dialog box for browsing the CMS
    //TODO after user selected the resource create a URL with a custom protocol
    //which will uniquely map to the resource on the CMS using the URLHandler
    //something like:
    URL customURL = new URL("mycms://host/path/to/file.xml");
    //Ask Oxygen to open the URL
    pluginWorkspaceAccess.open(customURL);
    //Oxygen will then your custom protocol handler to provide the contents for
    //the resource "mycms://host/path/to/file.xml"
    //Your custom protocol handler will check out the file in a temporary
    //directory, for example, and provide the content from it.
    //Oxygen will also pass through your URLHandler if you have any relative
    //references which need to be opened/obtained.
  }
```

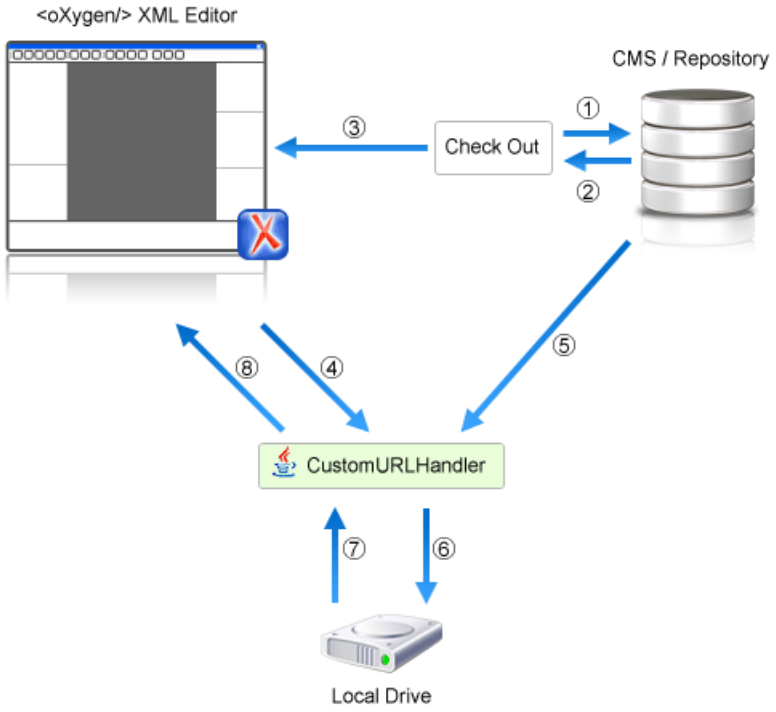

Figure 735: Check Out Process Diagram

Each phase is described below:

1. Browse CMS repository
2. User chooses a resource
3. Use API to open custom URL: `mycms://path/to/file.xml`
4. Get content of URL: `mycms://path/to/file.xml`
5. Get content of resource
6. Store on disk for faster access
7. Retrieve content from disk if already checked out
8. Retrieved content

- Contribute a special **Browse CMS** action to every dialog box in Oxygen XML Editor where a URL can be chosen to perform a special action (such as the **Reuse Content** or **Insert Image** action). Sample code:

```
      //Add an additional browse action to all dialog boxes/places
      //where Oxygen allows selecting a URL.
      pluginWorkspaceAccess.addInputURLChooserCustomizer
(new InputURLChooserCustomizer() {
        public void customizeBrowseActions
(List<Action> existingBrowseActions, final InputURLChooser chooser) {
          //IMPORTANT, you also need to set a custom icon on the action
          //for situations when its text is not used for display.
          Action browseCMS = new AbstractAction("CMS") {
            public void actionPerformed(ActionEvent e) {
              URL chosenResource = browseCMSAndChooseResource();
              if (chosenResource != null) {
                try {
                  //Set the chosen resource in the combo box chooser.
                  chooser.urlChosen(chosenResource);
                } catch (MalformedURLException e1) {
                  //
                }
              }
            }
          };
          existingBrowseActions.add(browseCMS);
        }
      });
```

When inserting references to other resources using the actions already implemented in Oxygen XML Editor, the reference to the resource is made by default relative to the absolute location of the edited XML file. You can gain control over the way in which the reference is made relative for a specific protocol like this:

```
      //Add a custom relative reference resolver for your custom protocol.
      //Usually when inserting references from one URL to another Oxygen
      //makes the inserted path relative.
      //If your custom protocol needs special relativization techniques then
      //it should set up a custom relative
      //references resolver to be notified when resolving needs to be done.
      pluginWorkspaceAccess.addRelativeReferencesResolver(
          //Your custom URL protocol for which you already have a
          //custom URLStreamHandlerPluginExtension set up.
          "mycms",
          //The relative references resolver
          new RelativeReferenceResolver() {
        public String makeRelative(URL baseURL, URL childURL) {
          //Return the referenced path as absolute for example.
          //return childURL.toString();
          //Or return null for the default behavior.
          return null;
        }
      });
```

- Write the `plugin.xml` descriptor file. Your *plugin* combines the two extensions using a single set of libraries. The descriptor would look like this:

```
<!DOCTYPE plugin SYSTEM "../plugin.dtd">
<plugin
 name="CustomCMSAccess"
 description="Test"
 version="1.0.0"
 vendor="ACME"
 class="custom.cms.CMSAccessPlugin">
 <runtime>
  <library name="lib/cmsaccess.jar"/>
 </runtime>
 <!--Access to add actions to the main menu and toolbars or to add custom views.-->
 <!--See the "CustomWorkspaceAccessPluginExtension" Java sample for more details-->
 <extension type="WorkspaceAccess"
  class="custom.cms.CustomWorkspaceAccessPluginExtension"/>
 <!--The custom URL handler that will communicate with the CMS implementation-->
 <!--See the "CustomProtocolURLHandlerExtension" Java sample for more details-->
 <extension type="URLHandler"
  class="custom.cms.CustomProtocolURLHandlerExtension"/>
</plugin>
```

- Create a `cmsaccess.jar` *JAR* archive containing your implementation classes.
- Copy your new *plugin* directory in the `plugins` subfolder of the Oxygen XML Editor install folder (for example, *`[OXYGEN_INSTALL_DIR]`*`/plugins/myPlugin`) and start Oxygen XML Editor.

Class Loading Issues

It is possible that the Java libraries you have specified in the *plugin* libraries list conflict with the ones already loaded by Oxygen XML Editor. To instruct the *plugin* to prefer its libraries over the ones used by Oxygen XML Editor, you can add the following attribute on the `<plugin>` root element: `classLoaderType="preferReferencedResources"` from the `plugin.xml` descriptor file.

A **Late Delegation Class Loader** (the main class loader in Oxygen XML Editor) is a `java.net.URLClassLoader` extension that prefers to search classes in its own libraries list and only if a class is not found there to delegate to the parent class loader.

The main Oxygen XML Editor Class Loader uses as libraries all *JARS* specified in the *`[OXYGEN_INSTALL_DIR]`*`\lib` directory. Its parent class loader is the default JVM Class loader. For each *plugin* instance, a separate class loader is created having as parent the Oxygen XML Editor Class Loader.

The *plugin* class loader can be either a standard `java.net.URLClassLoader` or a `LateDelegationClassLoader` (depending on the attribute `classLoaderType` in the `plugin.xml`). Its parent class loader is always the Oxygen XML Editor `LateDelegationClassLoader`.

If you experience additional problems, such as:

```
java.lang.LinkageError: ClassCastException:
attempting to cast
jar:file:/C:/jdk1.6.0_06/jre/lib/rt.jar!/
javax/xml/ws/spi/Provider.class
tojar:file:/D:/Program
 Files/Oxygen XML Editor
 12/plugins/wspcaccess/../../xdocs/lib/jaxws/
```

```
jaxws-api.jar!/javax/xml/ws/spi/Provider.class
 at javax.xml.ws.spi.Provider.provider(
Provider.java:94) at
 javax.xml.ws.Service.<init>(Service.java:56)
.........................................
```

The cause could be the fact that some classes are instantiated using the context class loader of the current thread. The most straightforward fix is to write your code in a *try/finally* statement:

```
ClassLoader oldClassLoader =
    Thread.currentThread().getContextClassLoader();
try {
  //This is the implementation of the
  //WorkspaceAccessPluginExtension plugin interface.
  Thread.currentThread().setContextClassLoader(
    CustomWorkspaceAccessPluginExtension.
      this.getClass().getClassLoader());
  //WRITE YOUR CODE HERE
} finally {
  Thread.currentThread().
   setContextClassLoader(oldClassLoader);
}
```

How to Write A Custom Protocol Plugin

To create a custom protocol *plugin*, follow these steps:

1. Write the handler class for your protocol that implements the *java.net.URLStreamHandler* interface.

   Be careful to provide ways to encode and decode the URLs of your files.
2. Write the *plugin* class by extending *ro.sync.exml.plugin.Plugin*.
3. Write the *plugin* extension class that implements the *ro.sync.exml.plugin.urlstreamhandler.URLStreamHandlerPluginExtension* interface.

   It is necessary that the *plugin* extension for the custom protocol implements the *URLStreamHandlerPluginExtension* interface. Without it, you cannot use your *plugin*, because Oxygen XML Editor is not able to find the protocol handler.

   You can choose also to implement the *URLChooserPluginExtension* interface. It allows you to write and display your own customized dialog box for selecting resources that are loaded with the custom protocol.

   An implementation of the extension *URLHandlerReadOnlyCheckerExtension* allows you to:

   - Mark a resource as read-only when it is opened.
   - Switch between marking the resource as read-only and read-write while it is edited.

   It is useful when opening and editing CMS resources.
4. Write the `plugin.xml` descriptor file.

   Remember to set the name of the *plugin* class to the one from the second step and the *plugin* extension class name with the one you have chosen at step 3.
5. Create a *JAR* archive with all these files.
6. Create a custom plugin folder inside the Oxygen **plugins** folder (for example, *[OXYGEN_INSTALL_DIR]*`/plugins/myPlugin`) that contains your new *plugin*.

Packing and Deploying Plugins or Frameworks as Add-ons

Packing a Plugin or Framework as an Add-on

This procedure is suitable for developers who want a better control over the *add-on* package or those who want to automate some of the steps:

1. Pack the *plugin* or *framework* as a `ZIP` file or a *Java Archive*. Note that you should pack the entire root directory not just its contents.
2. Digitally sign the package. Note that you can perform this step only if you have created a *Java Archive* at the previous step. You will need a certificate signed by a trusted authority. To sign the *JAR* you can either use the *jarsigner* command line tool inside Oracle's Java Development Kit. (`[JDK_DIR]/bin/jarsigner.exe`) or, if you are working with *Apache Ant*, you can use the *signjar* task (a front for the *jarsigner* command line tool).

Note: The benefit of having a signed add-on is that you can verify the integrity of the add-on issuer. If you do not have such a certificate you can generate one yourself using the *keytool* command line tool. This approach is mostly recommended for tests since anyone can create a self signed certificate.

3. Create a descriptor file. You can use a template that Oxygen XML Editor provides. To use this template, go to **File** > **New** and select the **Oxygen add-ons update site** template. Once deployed, this descriptor file is referenced as *update site*.

Alternatively, you can use the **Add-ons Packager** plugin by following this procedure:

1. Install the **Add-ons Packager** plugin from *https://www.oxygenxml.com/InstData/Addons/optional/updateSite.xml* as described in the *Installing Add-ons procedure*.
2. Restart Oxygen XML Editor. If the add-on is correctly installed, the **Add-ons packager** toolbar action is available.
3. Invoke the **Add-ons packager** toolbar action and input the required information in the displayed dialog box.
4. Press **OK** to complete the packaging process.

Deploying an Add-on

To deploy an add-on, copy the `ZIP` or *Java Archive* file and the descriptor file to an HTTP server. The URL to this location serves as the *Update Site URL*.

How to Share a Class Loader Between a Framework and Plugin

In some cases you may need to extend the functionality of Oxygen XML Editor both through a *framework* and through a *plugin*. Normally, a *framework* and a *plugin* both run in their own private classloader. If the *framework* and the *plugin* use the same JAVA extensions/classes, it is recommended that they share the same classloader. This way, the common classes are loaded by only one *Class Loader* and they will both use the same static objects and have the ability to cast objects between one another.

To do this, *open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Document Type Association**, select the document type, go to the **Classpath** tab, and in the **Use parent classloader from plugin with ID** fields introduce the ID of the *plugin*. This ID is declared in the *configuration file of the plugin*.

Important: The shared classes must be specified only in the configuration files of the *plugin*, and not in the configuration file and the document type class path at the same time.

Creating and Running Automated Tests

If you have developed complex custom *plugin* or *framework* (document types), the best way to test your implementation and ensure that further changes will not interfere with the current behavior is to make automated tests for your customization.

An Oxygen XML Editor standalone installation includes a main `oxygen.jar` library located in the *`[OXYGEN_INSTALL_DIR]`*. That *JAR* library contains a base class for testing developer customizations named: *ro.sync.exml.workspace.api.PluginWorkspaceTCBase*.

To develop *JUnit* tests for your customizations using the **Eclipse** workbench, follow these steps:

1. Create a new Eclipse Java project and copy to it the entire contents of the *`[OXYGEN_INSTALL_DIR]`*.
2. Add all *JAR* libraries present in the *`[OXYGEN_INSTALL_DIR]`*`/lib` directory to the **Java Build Path**->**Libraries** tab. Make sure that the main *JAR* library `oxygen.jar` or `oxygenAuthor.jar` is the first one in the Java classpath by moving it up in the **Order and Export** tab.
3. Click **Add Library** and add the *JUnit* and *JFCUnit* libraries.
4. Create a new Java class that extends *ro.sync.exml.workspace.api.PluginWorkspaceTCBase*.
5. Pass the following parameters on to the constructor of the super class:
   - `File installationFolder` - The file path to the main application installation directory. If not specified, it defaults to the folder where the test is started.
   - `File frameworksFolder` - The file path to the `frameworks` directory. It can point to a custom *framework* directory where it resides.
   - `File pluginsFolder` - The file path to the `plugins` directory. It can point to a custom *plugin* directory where it resides.

- `File optionsFolder` - The folder that contains the application options. If not specified, the application will auto-detect the location based on the started product ID.
- `String licenseKey` - The license key used to license the test class.
- `int productID` - The ID of the product and should be one of the following: `PluginWorkspaceTCBase.XML_AUTHOR_PRODUCT`, `PluginWorkspaceTCBase.XML_EDITOR_PRODUCT`, or `PluginWorkspaceTCBase.XML_DEVELOPER_PRODUCT`.

6. Create test methods that use the API in the base class to open XML files and perform various actions on them. Your test class could look something like this:

```
public class MyTestClass extends PluginWorkspaceTCBase {

/**
 * Constructor.
 */
public MyTestClass() throws Exception {
 super(null, new File("frameworks"), new File("plugins"), null,
"------START-LICENSE-KEY------\n" +
 "\n" +
 "Registration_Name=Developer\n" +
 "\n" +
 "Company=\n" +
 "\n" +
 "Category=Enterprise\n" +
 "\n" +
 "Component=XML-Editor, XSLT-Debugger, Saxon-SA\n" +
 "\n" +
 "Version=14\n" +
 "\n" +
 "Number_of_Licenses=1\n" +
 "\n" +
 "Date=09-04-2012\n" +
 "\n" +
 "Trial=31\n" +
 "\n" +
 "SGN=MCwCFGNoEGJSeiC3XCYIyalvjzHhGhhqAhRNRDpEu8RIWb8icCJO7HqfVP4++A\\=\\=\n" +
 "\n" +
"-------END-LICENSE-KEY-------",
 PluginWorkspaceTCBase.XML_AUTHOR_PRODUCT);
 }

 /**
   * <p><b>Description:</b> TC for opening a file and using a bold operation</p>
   * <p><b>Bug ID:</b> EXM-20417</p>
   *
   * @author radu_coravu
   *
   * @throws Exception
   */
public void testOpenFileAndBoldEXM_20417() throws Exception {
      WSEditor ed = open(new File
("D:/projects/eXml/test/authorExtensions/dita/sampleSmall.xml").toURL());
     //Move caret
     moveCaretRelativeTo("Context", 1, false);

     //Insert <b>
     invokeAuthorExtensionActionForID("bold");
     assertEquals("<?xml version=\"1.0\" encoding=\"utf-8\"?>\n" +
       "<!DOCTYPE task PUBLIC \"-//OASIS//DTD DITA Task//EN\"
 \"http://docs.oasis-open.org/dita/v1.1/OS/dtd/task.dtd\">\n" +
       "<task id=\"taskId\">\n" +
       "    <title>Task <b>title</b></title>\n" +
       "    <prolog/>\n" +
       "    <taskbody>\n" +
       "        <context>\n" +
       "            <p>Context for the current task</p>\n" +
       "        </context>\n" +
       "        <steps>\n" +
       "            <step>\n" +
       "                <cmd>Task step.</cmd>\n" +
       "            </step>\n" +
       "        </steps>\n" +
       "    </taskbody>\n" +
       "</task>\n" +
       "", getCurrentEditorXMLContent());
   }
}
```

Debugging a Plugin Using the Eclipse Workbench

To debug problems in the code of a *plugin* without having to re-bundle the *plugin's* Java classes in a *JAR* library, follow these steps:

1. *Download* and install Oxygen XML Editor.

2. Set up the *Oxygen SDK* following *this set of instructions*.
3. Create an Eclipse Java Project (for example, `MyPluginProject`) from one of the sample *plugins* (the Workspace Access plugin, for example).
4. In the `MyPluginProject` folder, create a folder called `myPlugin`. In this new folder copy the `plugin.xml` file from the sample *plugin*. Modify the added `plugin.xml` to add a library reference to the directory where Eclipse copies the compiled output. To find out where this directory is located, invoke the contextual menu of the project (in the ***Project** view*), and go to **Build Path** > **Configure Build Path**. Then inspect the value of the **Default output folder** text box.

   Example: If the compiled output folder is `classes`, then the you need to add in the `plugin.xml` the following library reference:

   ```
   <library name="../classes"/>
   ```
5. Copy the `plugin.dtd` from the *`[OXYGEN_INSTALL_DIR]`*`/plugins` folder in the root `MyPluginProject` folder.
6. In the `MyPluginProject` build path add external *JAR* references to all the *JAR* libraries in the *`[OXYGEN_INSTALL_DIR]`*`/lib` folder. Now your `MyPluginProject` should compile successfully.
7. In the Eclipse IDE, create a new *Java Application* configuration for debugging. Set the **Main class** box to `ro.sync.exml.Oxygen`. Click the **Arguments** tab and add the following code snippet in the **VM arguments** input box, making sure that the path to the `plugins` directory is the correct one:

   ```
   -Dcom.oxygenxml.app.descriptor=ro.sync.exml.EditorFrameDescriptor -Xmx1024m
   -XX:MaxPermSize=384m -Dcom.oxygenxml.editor.plugins.dir=D:\projects
   \MyPluginProject
   ```
8. *Add a breakpoint* in the source of one of your Java classes.
9. Debug the created configuration. When the code reaches your *breakpoint*, the Eclipse IDE debugging *perspective* should take over.

Debugging an Oxygen SDK Extension Using the Eclipse Workbench

To debug problems in an *extension* code without having to bundle its Java classes in a *JAR* library, perform the following steps:

1. *Download* and install Oxygen XML Editor.
2. Create an Eclipse Java Project (for example, `MySDKProject`) with the corresponding Java sources (for example, a custom implementation of the *ro.sync.ecss.extensions.api.StylesFilter* interface).
3. In the Project build path add external *JAR* references to all the *JAR* libraries in the *`[OXYGEN_INSTALL_DIR]`*`/lib` folder. Now your Project should compile successfully.
4. Start the standalone version of Oxygen XML Editor from the *`[OXYGEN_INSTALL_DIR]`* and in the ***Document Type Association** preferences page*, edit the document type (for example, **DITA**) to open the ***Document Type** configuration dialog box*. In the **Classpath** tab, add a reference to your Project's `classes` directory and in the **Extensions** tab, select your custom *StylesFilter* extension as a value for the **CSS styles filter** property. Close the application to save your changes.
5. Create a new Java Application configuration for debugging. The Main Class should be `ro.sync.exml.Oxygen`. The given VM Arguments should be

   ```
   -Dcom.oxygenxml.app.descriptor=ro.sync.exml.EditorFrameDescriptor -Xmx1024m -
   XX:MaxPermSize=384m
   ```
6. *Add a breakpoint* in one of the source Java classes.
7. Debug the created configuration. When the code reaches your *breakpoint*, the Eclipse IDE debugging *perspective* should take over.

Disabling a Plugin

To disable a *plugin*, use one of the following two methods:

- *Open the **Preferences** dialog box **(Options** > **Preferences)***, go to **Plugins**, and deselect the *plugin* that you want to disable.

- Create an empty file called `plugin.disable` next to the *plugin* configuration file (`plugin.xml`). The *plugin* will be disabled and will no longer be loaded by the application on startup.

  Note: This is useful if you want to temporarily stop work on a *plugin* and use the application without it.

Oxygen XML Author Component

The Oxygen XML Author Component was designed as a subset of Oxygen XML Editor that can be integrated into another application under the terms of the Oxygen XML Editor SDK agreement to provide functionality for editing and authoring XML documents. The component can be embedded in a third-party standalone Java application or customized as a Java Web Applet to provide WYSIWYG-like XML editing directly in your web browser.

The Oxygen XML Author Component startup project for *Java Swing* integrations is available online as a Maven archetype on the Oxygen XML Editor website. More information about the setup can be found on the *Oxygen SDK page*.

Licensing

The licensing terms and conditions for the Oxygen XML Author Component are defined in the ***Oxygen SDK License Agreement***. To obtain the licensing terms and conditions and other licensing information as well, you can also contact our support team at **support@oxygenxml.com**. You may also obtain a free of charge evaluation license key for development purposes, subject to registration. Any deployment of an application developed using the Oxygen XML Author Component is also subject to the terms of the SDK agreement.

There are two main categories of Oxygen XML Author Component integrations:

1. **Integration for internal use**.

   You develop an application that embeds the *Author Component* to be used internally (in your company or by you). You can buy and use previously purchased Oxygen XML Editor floating licenses to enable the runtime usage of the Oxygen XML Author Component as it was integrated into the application.
2. **Integration for external use**.

   Using the Oxygen XML Author Component, you create an application that you distribute to other users outside your company (with a CMS for example). In this case you need to contact us to apply for a Value Added Reseller (VAR) partnership.

From a technical point of view, the Oxygen XML Author Component provides the Java API to:

- Inject floating license server details in the Java code. The following link provides details about how to configure an HTTP floating license server: *https://www.oxygenxml.com/license_server.html#floating_license_servlet*.

```
AuthorComponentFactory.getInstance().init(frameworkZips,
  optionsZipURL, codeBase, appletID,
      //The servlet URL
      "http://www.host.com/servlet",
      //The HTTP credentials user name
      "userName",
      //The HTTP credentials password
      "password");
```

- Inject the licensing information key (for example, the evaluation license key) directly in the component's Java code.

```
AuthorComponentFactory.getInstance().init(
   frameworkZips, optionsZipURL, codeBase, appletID,
   //The license key if it is a fixed license.
   licenseKey);
```

- Display the license registration dialog box. This is the default behavior if a *null* license key is set using the API, this transfers the licensing responsibility to the end-user. The user can license an Oxygen XML Author Component using standard Oxygen XML Editor license keys. The license key will be saved to the local user's disk and on subsequent runs the user will not be asked anymore.

```
AuthorComponentFactory.getInstance().init(
   frameworkZips, optionsZipURL, codeBase, appletID,
```

```
    //Null license key, will ask the user.
    null);
```

Installation Requirements

Running the Oxygen XML Author Component as a Java applet requires:

- Oracle (Sun) Java JRE version 1.6 update 10 or newer.
- At least 100 MB disk space and 100MB free memory.
- The applet needs to be signed with a valid certificate and will request full access to the user machine to store customization data (such as options and *framework* files).
- A table of supported browsers can be found in *Supported Browsers and Operating Systems* on page 1579.

Running the Oxygen XML Author Component embedded in a third-party Java/Swing application requires:

- Oracle (Sun) Java JRE version 1.6 or newer.
- At least 100 MB disk space and 100MB free memory.

Customization

For a special type of XML, you can create a custom *framework* (which also works in a standalone version of Oxygen XML Editor). Oxygen XML Editor already has *frameworks* for editing DocBook, DITA, TEI, and so on. Their sources are available in *the Oxygen SDK*. This custom *framework* is then packed in a zip archive and used to deploy the component.

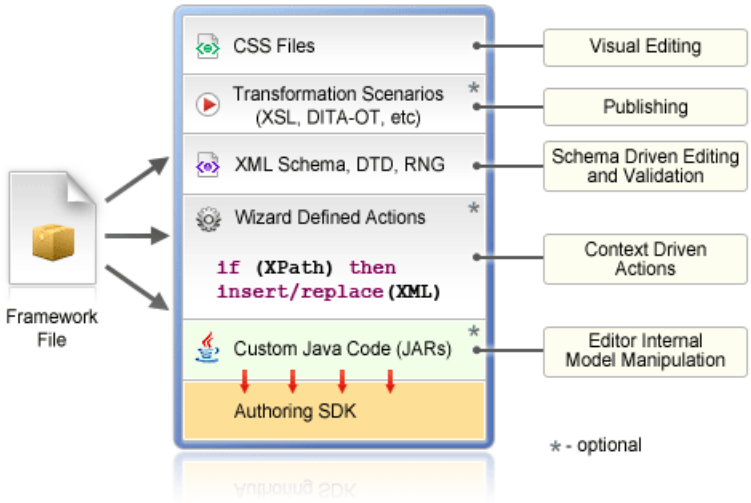

Figure 736: Components of a Custom Framework

Multiple *frameworks* can coexist in the same component and can be used at the same time for editing XML documents.

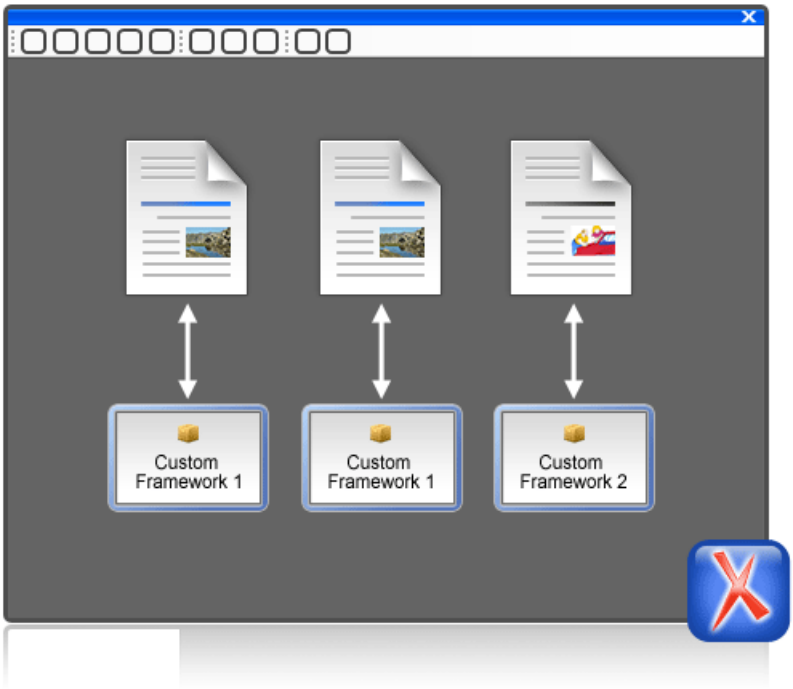

Figure 737: Multiple Frameworks

You can add on your custom toolbar all actions available in the standalone Oxygen XML Editor application for editing in the **Author** mode. You can also add custom actions defined in the *framework* customized for each XML type.

The Oxygen XML Author Component can also provide the ***Outline***, ***Model***, ***Elements***, and ***Attributes*** views, which can be added to your own developed containers.

The main entry point for the Oxygen XML Author Component Java API is the *AuthorComponentFactory* class.

Related Information:

Author Mode Customization Guide on page 1380

Oxygen XML Author Component on page 1574

AuthorComponentFactory API

Example - Customizing the DITA Framework

If you look inside the `bundle-frameworks\oxygen-frameworks` folder distributed with the *Oxygen XML Author Component sample project*, it contains a *framework* folder. Customizations that affect the *framework* configuration for the component should first be done in a standalone installation of Oxygen XML Editor.

An Oxygen XML Editor standalone installation includes a `frameworks` folder that contains the `dita` *framework* located in *`[OXYGEN_INSTALL_DIR]`*`\frameworks\dita`. The `dita` *framework* contains a bundled **DITA-OT** distribution which contains the DTDs used for DITA editing. If your DTD specialization is a DITA OT plugin, it *should be installed* in the *`DITA-OT-DIR`*`\plugins` folder.

To make changes to the DITA *framework* configuration, *open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to **Document Type Association**. These changes will affect the *`[OXYGEN_INSTALL_DIR]`*`\frameworks\dita\dita.framework` configuration file.

After you do this you can re-pack the Oxygen XML Author Component following the instructions from the README.html file located in the *oxygen-sample-applet* project. The *Author Component* sample project and the Oxygen XML Editor standalone installation should be of the same version.

Related Information:
Advanced Framework Customization on page 1385

Packing a Fixed Set of Options

The Oxygen XML Author Component shares a common internal architecture with the standalone application, although it does not have **Preferences** dialog boxes. However, the *Author Component Applet* can be configured to use a fixed set of user options on startup.

The sample project contains a module called `bundle-options`. The module contains a file called `options.xml` in the `oxygen-options` folder. Such an XML file can be obtained by exporting the options to an XML format from an installation of Oxygen XML Editor.

To create an *options file* in the Oxygen XML Editor:

- Make sure the options that you want to set are not *stored at project level*.
- Set the values you want to impose as defaults in the *Preferences pages*.
- Select **Options** > **Export Global Options**.

Deployment

The Oxygen XML Author Component Java API allows you to use it in your Java application or as a Java applet. The JavaDoc for the API can be found *here*. The sample project found in the `oxygen-sample-applet` module includes Java sources (`ro/sync/ecss/samples/AuthorComponentSample.java`) demonstrating how the component is created, licensed and used in a Java application.

Important: You must obtain the appropriate deployment license (upon payment of a required deployment license fee) to deploy the Oxygen XML Author Component along with your application developed with the SDK.

Web Deployment

The Oxygen XML Author Component can be deployed as a Java Applet using the new Applet with JNLP Java technology, available in Oracle (Sun) Java JRE version 1.6 update 10 or newer.

The *sample project* demonstrates how the Oxygen XML Author Component can be distributed as an applet.

To deploy the Oxygen XML Author Component as a Java Applet, consider the following notes:

- Follow the instructions *here* to setup the sample project and look for Java sources of the sample Applet implementation in the sample project module (**oxygen-sample-applet**). They can be customized to fit your requirements.
- The `default.properties` configuration file must first be edited to specify your custom certificate information used to sign the applet libraries. You also have to specify the code base from where the applet will be downloaded.
- You can look inside the `web-resources/author-component-dita.html` and `web-resources/author-component-dita.js` sample Web resources to see how the applet is embedded in the page and how it can be controlled using JavaScript (to set and get XML content from it).
- The sample Applet `target/jnlp/author-component-dita.jnlp` file contains the list of used libraries. This list is automatically generated from the Maven dependencies of the project.
- The sample *frameworks* and options *JAR* archives can be found in the `bundle-frameworks` and `bundle-options` modules of the sample project.
- Use the Maven command `mvn package` to pack the component. More information are available *here*. The resulting applet distribution is copied in the `target/jnlp/` directory. From this on, you can copy the applet files on your web server.

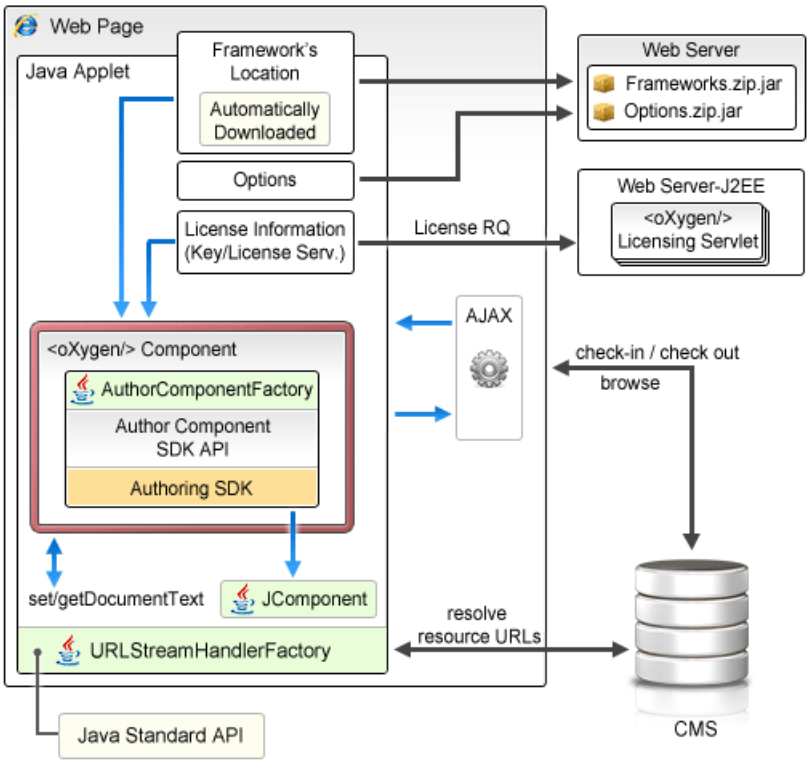

Figure 738: Oxygen XML Author Component Deployed as a Java Applet

Generate a Testing Certificate for Signing an Applet

All *JAR* files of an applet deployed on a remote Web server must be signed with the same certificate before the applet is deployed. The following steps describe how to generate a test certificate for signing the *JAR* files. We will use the tool called **Keytool**, which is included in the Oracle Java Development Kit.

1. Create a *keystore* with an RSA encryption key.

   Invoke the following in a command-line terminal:

   ```
   keytool -genkey -alias myAlias -keystore keystore.pkcs -storetype PKCS12 -
   keyalg RSA -keysize 2048 -dname "cn=your name here, ou=organization unit name,
    o=organization name, c=US"
   ```

   This command creates a *keystore* file called `keystore.pkcs`. The certificate attributes are specified in the `dname` parameter: common name of the certificate, organization unit name (for example, *Purchasing* or *Sales Department*), organization name, country.
2. Generate a self-signed certificate.

   Invoke the following in a command-line terminal:

   ```
   keytool -selfcert -alias myAlias -keystore keystore.pkcs -storetype PKCS12
   ```
3. Optionally display the certificate details in a human readable form.

   First, the certificate must be exported to a separate file with the following command:

   ```
   keytool -export -alias myAlias -keystore keystore.pkcs -storetype PKCS12 -file
    certfile.cer
   ```

   The certificate details are displayed with the command:

   ```
   keytool -printcert -file certfile.cer
   ```

4. Edit the `default.properties` file and fill-in the parameters that hold the path to `keystore.pkcs` file (`keystore` parameter), *keystore* type (`storetype` parameter, with JSK or PKCS12 as possible values), alias (`alias` parameter) and password (`password` parameter).
5. The *JAR* files are automatically signed during the *package* phase of the Maven build.

Supported Browsers and Operating Systems

The applet was tested for compatibility with the following browsers:

	IE 7	IE 8	IE 9	IE 10	IE 11	Edge	Firefox	Safari	Chrome	Opera
Vista	-	Passed	Passed	Passed	Passed		Passed	-	Passed	Passed
Windows 7	-	-	Passed	Passed	Passed		Passed	-	Passed	Passed
Windows 8	-	-	-	Passed	Passed		Passed	-	Passed	Passed
Windows 10	-	-	-	-	-	Passed	Passed	-	Passed	Passed
OS X (10.6 - 10.9)	-	-	-	-	-		Passed	Passed	Failed	Passed
Linux Ubuntu 10	-	-	-	-	-		Passed	-	Failed	Passed

Communication Between the Web Page and Java Applet

Applets can communicate with JavaScript code that runs in the Web Page. JavaScript code can call an applet Java methods and from the Java code you can invoke JavaScript code from the web page.

You are not limited to displaying only *Swing* dialog boxes from the applet. From the operations of an applet, you can invoke a JavaScript API that displays a web page and then obtains the data that has been filled in by the user.

Troubleshooting the Applet

When the applet fails to start:

1. Make sure that your web browser really runs the next generation Java plugin and not the legacy Java plugin.

   For Windows and OS X the procedure is straight forward. Some steps are given below for installing the Java plugin on Linux.

   Manual Installation and Registration of Java Plugin for Linux: *http://www.oracle.com/technetwork/java/javase/manual-plugin-install-linux-136395.html*
2. Refresh the web page.
3. Remove the Java Webstart cache from the local drive and try again.
   - On Windows this folder is located in: `%APPDATA%\LocalLow\Sun\Java\Deployment\cache`.
   - On OS X this folder is located in: `/Users/user_name/Library/Caches/Java/cache`.
   - On Linux this folder is located in: `/home/user/.java/deployment/cache`.
4. Remove the Oxygen XML Author Component cache from the local drive and try again:
   - On Windows Vista/7/8/10 this folder is located in: `%APPDATA%\Roaming\com.oxygenxml.author.component`.
   - On Windows XP this folder is located in: `%APPDATA%\com.oxygenxml.author.component`.
   - On OS X this folder is located in: `/Users/user_name/Library/Preferences/com.oxygenxml.author.component`.
   - On Linux this folder is located in: `/home/user/.com.oxygenxml.author.component`.

5. Problems sometimes occur after upgrading the web browser and/or the JavaTM runtime. Redeploy the applet on the server by running Ant in your Oxygen XML Author Component project. However, doing this does not always fix the problem, which often lies in the web browser and/or in the Java plugin itself.
6. Sometimes when the HTTP connection is slow on first time uses the JVM would simply shut down while the *JARS* were being pushed to the local cache (for example, first time uses). This shut down typically occurs while handling `oxygen.jar`. One of the reasons could be that some browsers (Firefox, for example) implement some form of "Plugin hang detector" See *https://developer.mozilla.org/en/Plugins/Out_of_process_plugins/The_plugin_hang_detector*.
7. If you are running the Applet using Safari on OS X and it has problems writing to disk or fails to start, do the following:
   - In Safari, go to **Safari**->**Preferences**->**Security**.
   - Select **Manage Website Settings**.
   - Then select Java and for the *oxygenxml.com* entry, choose the **Run in Unsafe mode** option.

Enable JavaWebstart logging on your computer to get additional debug information:

1. Open a console and run `javaws -viewer`.
2. In the **Advanced** tab, expand the **Debugging** category and select all boxes.
3. Expand the **Java console** category and choose **Show console**.
4. Save settings.
5. After running the applet, you will find the log files in:
   - On Windows this folder is located in: `%APPDATA%\LocalLow\Sun\Java\Deployment\log`.
   - On OS X this folder is located in: `/Users/user_name/Library/Caches/Java/log`.
   - On Linux this folder is located in: `/home/user/.java/deployment/log`.

Avoiding Resource Caching

A Java plugin installed in a web browser caches access to all HTTP resources that the applet uses. This is useful to avoid downloading all the libraries each time the applet is run. However, this may have undesired side-effects when the applet presents resources loaded via HTTP. If such a resource is modified on the server and the browser window is refreshed, you might end-up with the old content of the resource presented in the applet.

To avoid such a behavior, you need to edit the `ro.sync.ecss.samples.AuthorComponentSampleApplet` class and set a custom `URLStreamHandlerFactory` implementation. A sample usage is already available in the class, but it is commented-out for increased flexibility:

```
//THIS IS HOW YOU CAN REGISTER YOUR OWN PROTOCOL HANDLER TO THE JVM.
//THEN YOU CAN OPEN YOUR CUSTOM URLs IN THE APPLET AND IT WILL USE YOUR HANDLER
URL.setURLStreamHandlerFactory(new URLStreamHandlerFactory() {
 public URLStreamHandler createURLStreamHandler(String protocol) {
  if("http".equals(protocol) || "https".equals(protocol)) {
   return new URLStreamHandler() {
    @Override
    protected URLConnection openConnection(URL u) throws IOException {
     URLConnection connection = new HttpURLConnection(u, null);
     if(!u.toString().endsWith(".jar")) {
      //Do not cache HTTP resources other than JARS
      //By default the Java HTTP connection caches content for
      //all URLs so if one URL is modified and then re-loaded in the
      //applet the applet will show the old content.
      connection.setDefaultUseCaches(false);
     }
     return connection;
    }
   };
  }
  return null;
 }
});
```

Adding MathML support in the Oxygen XML Author Component Web Applet

By default, the Oxygen XML Author Component Web Applet project does not come with the libraries necessary for viewing and editing MathML equations in the **Author** mode. You can view and edit MathML equations either by adding support for *JEuclid* or by adding support for *MathFlow*.

Adding MathML Support Using JEuclid

By default, the *JEuclid* library is excluded from the *Oxygen SDK* artifact dependencies. To enable it, comment the following lines in the `pom.xml` file:

```
<exclusion>
    <artifactId>jeuclid-core</artifactId>
    <groupId>net.sourceforge.jeuclid</groupId>
</exclusion>
```

To edit specialized DITA Composite with MathML content, include the entire MathML2 *framework* directory (*[OXYGEN_INSTALL_DIR]*`/frameworks/mathml2`) in the *frameworks* bundled with the component in the `bundle-frameworks` module. This directory is used to solve references to MathML DTDs.

Adding MathML support using MathFlow

In the `pom.xml` file add dependencies to the additional libraries used by the MathFlow library to parse MathML equations:

1. `MFComposer.jar`
2. `MFExtraSymFonts.jar`
3. `MFSimpleEditor.jar`
4. `MFStructureEditor.jar`
5. `MFStyleEditor.jar`

Note: For MathFlow 2.1, all of these *JAR* files are packaged into one file called `MathFlow.jar`.

You can reference these additional libraries from the MathFlow SDK as in the example below:

```
<dependency>
    <groupId>com.dessci</groupId>
    <artifactId>MFComposer</artifactId>
    <version>1.0.0</version>
    <scope>system</scope>
    <systemPath>${MathFlowSDKDir}/lib/MFComposer.jar</systemPath>
</dependency>
```

In addition, you must obtain fixed MathFlow license keys for editing and composing *MathML* equations and register them using these API methods: *AuthorComponentFactory.setMathFlowFixedLicenseKeyForEditor* and *AuthorComponentFactory.setMathFlowFixedLicenseKeyForComposer*.

To edit specialized DITA Composite with *MathML* content, include the entire *[OXYGEN_INSTALL_DIR]*`/frameworks/mathml2` Mathml2 *framework* directory in the *frameworks* bundled with the component in the `bundle-frameworks` module. This directory is used to solve references to *MathML* DTDs.

More documentation is available on the *Design Science MathFlow* website.

Adding Support to Insert References from a WebDAV Connection

Predefined actions that insert references, such as the **Insert Image** action, includes a URL chooser field with a drop-down menu that allows you to select a **Browse Data Source Explorer** action. This action opens the ***Data Source Explorer*** that allows you to view a WebDAV connection.

To use a WebDAV connection in the Oxygen XML Author Component, follow these steps:

1. Open a standalone Oxygen XML Editor 19.1 and *configure a WebDAV connection*.
2. Pack the *fixed set of options* from the standalone to use them with the Oxygen XML Author Component project.
3. In the Oxygen XML Author Component, the defined connection still does not work when expanded because the additional *JAR* libraries used to browse the WebDAV repository are missing. By default, the **httpclient** dependency of the *Oxygen SDK* artifact is excluded. You can enable it by commenting the following lines:

   ```
   <exclusion>
       <artifactId>httpclient</artifactId>
       <groupId>org.apache.httpcomponents</groupId>
   </exclusion>
   ```

If you want to have multiple WebDAV connection URLs, user names, and passwords (depending on the user who started the component), you can use a more flexible approach by using the following API:

```
    //DBConnectionInfo(String id, String driverName, String url, String user,
String passwd, String host, String port)
    DBConnectionInfo info = new DBConnectionInfo("WEBDAV", "WebDAV FTP",
"http://host/webdav-user-root", "userName", "password", null, null);
    AuthorComponentFactory.getInstance().setObjectProperty
("database.stored.sessions1", new DBConnectionInfo[] {info});
```

Using Plugins with the Oxygen XML Author Component

To bundle Workspace Access *plugins* that are developed for standalone application with the Oxygen XML Author Component, follow these steps:

- The `bundle-plugins` module must contain the additional plugin directories in the `dropins` subdirectory. The content must also contain a `plugin.dtd` file. Copy the `plugin.dtd` file from an *`[OXYGEN_INSTALL_DIR]`*`\plugins` folder.
- In the class that instantiates the *AuthorComponentFactory*, for example the *ro.sync.ecss.samples.AuthorComponentSample* class, call the methods *AuthorComponentFactory.getPluginToolbarCustomizers()*, *AuthorComponentFactory.getPluginViewCustomizers()* and *AuthorComponentFactory.getMenubarCustomizers()*, obtain the customizers that have been added by the plugins and call them to obtain the custom swing components that they contribute. There is a commented-out example for this in the *AuthorComponentSample.reconfigureActionsToolbar()* method for adding the toolbar from the **Acrolinx** plugin.

Important: As the Oxygen XML Author Component is just a subset of the entire application, there is no guarantee that all the functionality of the plugin works.

Sample SharePoint Integration of the Oxygen XML Author Component

This section presents the procedure to integrate the Oxygen XML Author Component as a Java applet on a SharePoint site.

Microsoft SharePoint®

Microsoft SharePoint® is a Web application platform developed by Microsoft®.

SharePoint comprises a multipurpose set of Web technologies backed by a common technical infrastructure. It provides the benefit of a central location for storing and collaborating on documents, which can significantly reduce emails and duplicated work in an organization. It is also capable of keeping track of the multiple versions created by multiple users.

Why Integrate the Oxygen XML Author Component with SharePoint

The Oxygen XML Author Component can be embedded in a SharePoint site as a Java applet. This is a simple and convenient way for you to retrieve, open, and save XML and XML related documents stored on your company's SharePoint server, directly from your web browser.

For example, suppose that you are working on a team project that uses the DITA *framework* for writing product documentation and you have the *DITA maps* and topics stored on a SharePoint repository. By using a custom defined action from the contextual menu of a document, you can easily open it in the Oxygen XML Author Component applet that is embedded in your SharePoint Documents page.

You can embed the applet either on a site that is located on a standalone SharePoint server, or on your company Microsoft Office 365 account.

This example can be used as a starting point for other CMS integrations.

Deploying Resources

You can embed the Oxygen XML Author Component in a SharePoint site as a Java Applet, using the new Applet with JNLP Java technology. Sign with a valid certificate the JNLP file and the associated *JAR* files that the applet needs.

Deploy these resources on a third party server (other than the SharePoint server). The Java applet downloads the resources as needed. If you deploy the JNLP and *JAR* files on the SharePoint server, the Java Runtime Environment will not be able to access the applet resources because it is not aware of the current authentication tokens from your browser. This causes the Java Class Loader to fail loading classes, making the applet unable to start.

Accessing Documents

One of the main challenges when integrating the Oxygen XML Author Component applet in your SharePoint site is to avoid authenticating twice when opening a document resource stored in your SharePoint repository.

You have already signed in when you started the SharePoint session, but the applet is not aware of your current session. In this case every time the applet is accessing a document it will ask you to input your credentials again.

As a possible solution, do not execute HTTP requests directly from the Java code, but forward them to the web browser that hosts the applet, because it is aware of the current user session (authentication cookies).

To open documents stored on your SharePoint repository, register your own protocol handler to the JVM. We implemented a handler for both *http* and *https* protocols that forwards the HTTP requests to a JavaScript `XMLHttpRequest` object. This way, the browser that executes the JavaScript code is responsible for handling the authentication to the SharePoint site.

To install this handler, add the following line to your Java Applet code (in our case, in the `ro.sync.ecss.samples.AuthorComponentSampleApplet` class):

```
URL.setURLStreamHandlerFactory(new
  ro.sync.net.protocol.http.handlers.CustomURLStreamHandlerFactory(this));
```

To allow JavaScript calls from your Java applet code, set the MAYSCRIPT attribute to `true` in the `<applet>` element embedded in you HTML page:

```
<applet width="100%" height="600"
  code="ro.sync.ecss.samples.AuthorComponentSampleApplet"
  name="authorComponentAppletName" id="authorComponentApplet"
  MAYSCRIPT="true">
    .....
</applet>
```

Tip: If the applet is not working, or you cannot open documents from your SharePoint repository, enable the debugging tools that come bundled with your Web Browser or the Java Console from your operating system to try to identify the cause of the problem.

Integrating the Oxygen XML Author Component

To integrate the Oxygen XML Author Component as a Java applet with your SharePoint site, you need the Oxygen XML Author Component start-up project.

The project is available as a Maven archetype online. For more information about the setup, go to the *Oxygen XML SDK Website*.

Customize Your Applet

Follow these steps to customize the Oxygen XML Author Component Java applet:

1. Follow *this set of instructions* to setup the sample project and look for the Java sources (these can be customized to fit your requirements) of the sample applet implementation;

   Note: The Java source files are located in the `src` folder of the `oxygen-sample-applet` module.
2. Look inside `web-resources/sharepoint/author-component-dita.aspx` and the associated `*.js` resources, to see how the applet is embedded in the page and how it can be controlled using JavaScript (to set and get XML content from it).
3. Edit the `default.properties` configuration to specify your custom certificate information, used to sign the applet libraries. Also, specify the code base from where the applet resources will be downloaded.
4. The sample Applet `target/jnlp/author-component-dita.jnlp` file contains the list of used libraries. This list is automatically generated from the Maven dependencies of the project. The sample *frameworks* and options *JAR* archives are located in the `bundle-frameworks` and `bundle-options` modules of the sample project.

Note: The JNLP file and the associated resources and libraries must be deployed on a non-SharePoint web server. Otherwise, the applet will not be loaded.

5. Use the Maven command `mvn package` to pack the component. More information are available *here*. The resulting applet distribution is copied in the `target/jnlp/` directory. From now on, you can copy the applet files on your web server.

Add Resources to Your SharePoint Site

Copy the following resources to a sub-folder (in our example named `author-component`) of the `SitePages` folder from your SharePoint site, where you want to embed the applet:

1. **`author-component-dita.aspx`** - an HTML document containing the Java applet.

   Note: It has an `.aspx` extension instead of `.html`. If you use the latter extension, the browser will download the HTML document instead of displaying it.

   Note: Edit the **`.aspx`** file and change the value of the applet parameter jnlp_href to the URL of the deployed `author-component-dita.jnlp`. Keep in mind that the JNLP file should be deployed on a third party server. For example:

   ```
   <applet>
       <param name="jnlp_href"
           value="http://www.oxygenxml.com/DemoApplet/author-component-dita.jnlp"/>
       ..........
   </applet>
   ```

2. **`author-component-dita.css`** - contains custom styling rules for the HTML document.
3. **`author-component-dita.js`** - contains JavaScript code, giving access to the Oxygen XML Author Component contained by the Java applet.
4. **`connectionUtil.js`** - contains JavaScript utility methods.

   Note: Replace the value of the SPRootSiteURL property with the URL of your SharePoint root site, without trailing `'/'`. This is used by the `openListItemInAuthor(itemUrl)` method, to compute the absolute URL of the list item that is to be opened in the applet.

Copy Resources Using Oxygen XML Editor

You can use Oxygen XML Editor to copy your resources to the SharePoint server:

1. Configure a new connection to your SharePoint site in the ***Data Source Explorer** view*.
2. Browse your new SharePoint connection site and select the **`SitePages`** folder.
3. Create a folder named `author-component` using the **New Folder** contextual menu action.
4. Upload your resources to this folder using the **Import Files** contextual menu action.

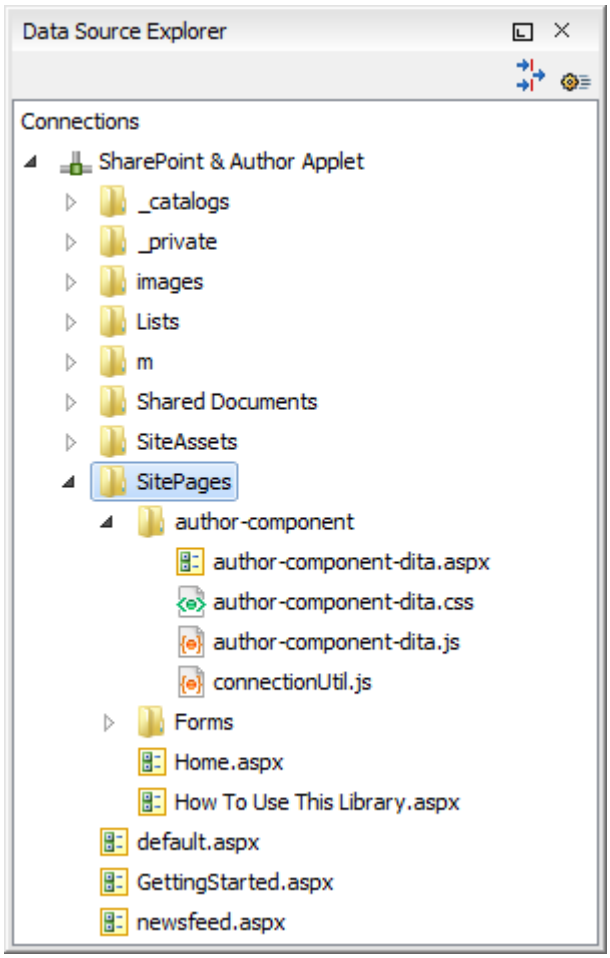

Figure 739: Data Source Explorer View

Embed the Java Applet in Your SharePoint Site

To embed the Java Applet in your SharePoint site, edit the page that contains the applet and add a new Script Editor Web Part next to an existing Documents web part.

Note: It is recommended that you deselect the **Enable Java content in the browser** option from the **Java Control Panel** until you finish editing the page. Otherwise, the browser will load the applet for every change that you will make.

Edit the page directly in your browser, following these steps:

1. Go to the home page of your SharePoint site where you want to add the *Author Component* Java applet.
2. Select the **Page** tab from the ribbon located at top of the page and click the **Edit** button.
3. Select the **Insert** tab and click **Web Part**.
4. In the **Categories** panel, select **Media and Content**.
5. In the **Parts** panel, select the **Script Editor** Web Part.
6. Click the **Add** button to insert the selected Web Part to your page content.
7. Select the newly added Web Part.
8. Select the **Web Part** tab and click the **Web Part Properties** button.
9. Click the **Edit Snippet** link under your Web Part.
10. Insert the following HTML snippet to your newly created Web Part:

```
<div>
    <iframe
       id="appletIFrame"
       src="/applet/SitePages/author-component/author-component-dita.aspx"
       width="800px" height="850px">
    </iframe>
    <script type="text/JavaScript">
        function openInAuthor(itemUrl) {
```

```
            var appletFrame = document.getElementById("appletIFrame");
            var appletWin = appletFrame.contentWindow;
            appletWin.openListItemInAuthor(itemUrl);
        }
    </script>
</div>
```

The above HTML fragment contains an `IFrame` that points to the page where the Java applet resides. Replace the value of the `src` attribute with the path of the `author-component-dita.aspx` HTML page that you added earlier to the `SitePages` folder;

Note: Use the `iframe` element from the HTML fragment with the expanded form (`<iframe></iframe>`). Otherwise, the Web Part will not display the target page of the frame.

11. Save the changes you made to the page.

Note: Do not forget to select the **Enable Java content in the browser**, to allow the browser to load the Java applet.

Create a SharePoint Custom Action

To open a document from your SharePoint repository in the Oxygen XML Author Component applet, add a new custom action to the contextual menu of your Documents Library:

1. Open your SharePoint site in **Microsoft SharePoint Designer**®.
2. Click **Lists and Libraries** in the **Navigation** pane.
3. Open the **Documents** library.
4. Go to the **Custom Actions** panel.
5. Click the **New** button to add a new custom action.
6. Give a name to the action (for example, `Open In Oxygen XML Author`).
7. In the **Select the type of action** section, select the **Navigate to URL** option and enter the following text:

```
javascript:openInAuthor("{ItemUrl}")
```

Note: This translates to a call to the `openInAuthor(itemUrl)` JavaScript function defined in the HTML fragment that was embedded in the Script Editor Web Part. The `{ItemUrl}` parameter will be expanded to the URL of the list item that the action is invoked on.

8. Click the **OK** button to save the action.

Integration Result

Frequently Asked Questions

Installation and Licensing

1. What hosting options are available for applet delivery and licensing services (for example, Apache, IIS, etc.)?

   For applet delivery any web server. We currently use Apache to deploy the sample on our site. For the floating license server you would need a J2EE server (such as Tomcat) if you want to restrict the access to the licenses.

   If you do not need the access restrictions that are possible with a J2EE server you can simplify the deployment of the floating license server by using the TCP version of this server. The TCP license server is a simple Java application that communicates with the Oxygen XML Author Component by TCP/IP connections.
2. Are there any client requirements beyond the Java VM and (browser) Java PlugIn Technology?

   Oracle (formerly Sun) Java JRE version 1.6 update 10 or newer. At least 200 MB disk space and 200MB free memory would be necessary for the Oxygen XML Author Component applet.
3. Are there any other client requirements or concerns that could make deployment troublesome (for example, browser security settings, client-side firewalls, and AV engines)?

   The applet is signed and will request access to the user machine to store *framework* customization data. The applet needs to be signed with a valid certificate.
4. How sensitive is the applet for the automatic Java VM updates that are typically on by default (for example, could automatic updates potentially "break" the run-time)?

   The component should work well with newer Java versions but we cannot guarantee this.
5. How and when are "project" related files deployed to the client (for example, applet code, DTD, styling files, customizations, etc.)?

   Framework files are downloaded on the first load of the applet. Subsequent loads will re-use the cached customization files and will be much faster.
6. For on-line demo (`http://www.oxygenxml.com/demo/AuthorDemoApplet/author-component-dita.html`), noted a significant wait during initial startup. Any other mechanisms to enhance startup time?

See the explanation above.

7. Does the Oxygen XML Author Component support multiple documents being open simultaneously? What are the licensing ramifications?

   A single *AuthorComponentFactory* instance can create multiple *EditorComponentProvider* editors that can then be added and managed by the developer who is customizing the component in a Swing *JTabbedPane*. A single license (floating or user-based) is enough for this.

   If you need to run multiple Java Applets or distinct Java processes using the Oxygen XML Author Component, the current floating license model allows for now only two concurrent components from the same computer when using the HTTP floating license server. An additional started component will take an extra license seat.
8. Is there any internet traffic during an editing session (user actively working on the content, on the client side, in the Oxygen XML Author Component)?

   No.

Functionality

1. How and when are saves performed back to the hosting server?

   What you can see on our web site is just an example of the Oxygen XML Author Component (which is a Java Swing component) used in an Applet.

   This applet is just for demonstration purposes. It's source can be at most a starting point for a customization. You should implement, sign and deploy your custom applet implementation.

   The save operation could be implemented either in JavaScript by requesting the XML content from the Applet or in Java directly working with the Oxygen XML Author Component. You would be responsible to send the content back to the CMS.
2. Is there a particular XML document size (or range) when the applet would start to exhibit performance problems?

   The applet has a total amount of used memory specified in the JNLP JavaWebstart configuration file, which can be increased if necessary. By default, it is 156 Mb. It should work comfortably with documents of 1-3 megabytes.
3. What graphic formats can be directly rendered in the Oxygen XML Author Component?

   GIF, JPEG, PNG, BMP and SVG.
4. Can links be embedded to retrieve (from the server) and "play" other types of digital assets, such as audio or video files?

   You could add listeners to intercept clicks and open the clicked links. This would require a good knowledge of the *Oxygen SDK*. The Oxygen XML Author Component can only render static images (no GIF animations).
5. Does the Oxygen XML Author Component provide methods for uploading ancillary files (new graphics, for instance) to the hosting server?

   No.
6. Does the Oxygen XML Author Component provide any type of autosave functionality?

   By default no but you could customize the applet that contains the Oxygen XML Author Component to save its content periodically to a file on disk.
7. Assuming multiple documents can be edited simultaneously, can content be copied, cut and pasted from one Oxygen XML Author Component "instance" to another?

   Yes.
8. Does the Oxygen XML Author Component support pasting content from external sources (such as a web page or a Microsoft Word document and, if so, to what extent?

   If no customizations are available the content is pasted as simple text. We provide customizations for the major *frameworks* (DITA, DocBook, TEI, etc.) that use a conversion XSLT stylesheet to convert HTML content from clipboard to the target XML.
9. Can UTF-8 characters (such as Greeks, mathematical symbols, etc.) be inserted and rendered?

Any UTF-8 character can be inserted and rendered, provided that the font used for editing supports rendering the characters. The font can be changed by developers but not by the users. When using a logical font (by default, *Serif* for the Oxygen XML Author Component), the JVM will know how to map all characters to glyphs. There is no character map available but you could implement one

Customization

1. Please describe, in general terms, the menus, toolbars, contextual menu options, helper panes, and so on, that are available for the Oxygen XML Author Component out-of-the box.

   You can mount on your custom toolbar all actions available in the standalone Oxygen XML Editor application for editing in the **Author** mode. This includes custom actions defined in the *framework* customized for each XML type.

   The Oxygen XML Author Component also can provide the ***Outline***, ***Model***, ***Elements***, and ***Attributes*** views that can be added to your own panels (see sample applet).
2. Please describe, in general terms, the actions, project resources (for example, DTD/Schema for validation purposes, CSS/XSL for styling, etc.) and typical level of effort that would be required to deploy a Oxygen XML Author Component solution for a customer with a proprietary DTD.

   The **Author** mode internal engine uses CSS to render XML.

   For a special type of XML, you can create a custom *framework* (which also works in an Oxygen XML Editor standalone version) that would also contain default schemas and custom actions. A simple *framework* would probably need 2-3 weeks development time. For a complex *framework* with many custom actions it could take a couple of months. Oxygen XML Editor already has *frameworks* for editing (DocBook, DITA, TEI, etc.) Sources for them are available in *the Oxygen SDK*.

   Multiple *frameworks* can co-exist in the same Oxygen XML Editor instance (the desktop standalone version or the applet version) and can be used at the same time for editing XML documents.
3. Many customers desire a very simplistic interface for contributors (with little or no XML expertise) but a more robust XML editing environment for editors (or other users with more advanced XML expertise). How well does the Oxygen XML Author Component support varying degrees of user interface complexity and capability?

   - *Showing/hiding menus, toolbars, helpers, etc.*

     You assemble all the UI parts from the Oxygen XML Author Component. For example, you could provide two applet implementations: one for advanced users and one for content authors.
   - *Forcing behaviors (for example, ensuring change tracking is on and preventing it from being shut down).*

     You could avoid placing the *change tracking* toolbar actions in the custom applet. You could also use API to turn *change tracking* ON when the content has been loaded.
   - *Preventing access to "privileged" editor processes (for example, accept/reject changes).*

     You can remove the *change tracking* actions completely in a custom applet implementation. Including the ones from the contextual menu.
   - *Presenting and/or describing XML constructs (for example, tags) in "plain-English".*

     Using our API, you can customize what the Outline or Breadcrumb presents for each XML tag. You can also customize the in-place content completion list.
   - *Presenting a small subset of the overall XML tag set (rather than the full tag set) for use by contributors (for example, allowing an author to only insert Heading, Para and inline emphasis).*

     The API allows for a content completion filter that also affects the *Elements* view.
4. Does the Oxygen XML Author Component API provide access to the XML document, for manipulation purposes, using common XML syntax (such as DOM, XPath, etc.)?

   Yes, using the Oxygen XML Author Component API.
5. Can custom dialog boxes be developed and launched to collect information in a "form" (with scripting behind to push tag the collection information and embed it in the XML document?

   Yes.
6. Can project resources and customizations be readily shared between the desktop and component versions of your Oxygen XML Author Component product line?

A *framework* developed for the desktop version of the Oxygen XML Editor application can then be bundled with the Oxygen XML Author Component in a custom applet. For example, the demo applet from our web site is DITA-aware using the same *framework* as the Oxygen XML Editor standalone distribution.

A custom version of the applet that includes one or more customized *frameworks* and user options can be built and deployed for non-technical authors by a technical savvy user using a built-in tool of Oxygen XML Editor. All the authors that load the deployed applet from the same server location will share the same *frameworks* and options.

A custom editing solution can deploy one or more *frameworks* that can be used at the same time.

Print Document Within the Oxygen XML Author Component

Question

Can a document be printed within the Oxygen XML Author Component?

Answer

You can use the following API method to either print the document content to the printer or to show the Print Preview dialog box, depending on the `preview` parameter value:

```
AuthorComponentProvider.print(boolean preview)
```

Here is the online Javadoc for this method: *https://www.oxygenxml.com/InstData/Editor/SDK/javadoc/ro/sync/ecss/extensions/api/component/AuthorComponentProvider.html#print(boolean)*

Feature Matrix

Oxygen XML Web Author was designed to provide the functionality of the **Author** mode in Oxygen XML Editor/Author in a mobile-friendly platform and can be embedded either in a third-party standalone Java application or customized as a Java Web Applet to provide WYSIWYG-like XML editing and reviewing directly in your choice of web browsers on your mobile devices or desktops.

Table 78: Feature Matrix Showing Differences Between Web Author and Oxygen XML Editor/Author

Feature	Oxygen XML Web Author	Oxygen XML Editor/Author
Intended audience	Reviewers and occasional contributors.	Content authors, technical writers.
Mobile device friendly	Specifically designed for mobile devices.	No
Compatibility with the standard versions of Oxygen	Covers only editing and reviewing features.	100%
Author mode	Yes	Yes
Text mode	Yes	Yes
Grid mode	No	Yes
Schema **Design** mode	No	Yes
Client-side setup	Yes, with an *Administration* page.	Requires Java to be installed, and Java Applets to be allowed to run.
Server-side setup	Requires running an installer or a servlet (along with performing a Maven build).	Requires a web server.

Oxygen XML Web Author

The *Oxygen SDK* includes a sample project that you can use to integrate the Oxygen XML Web Author into your existing content ecosystem and it allows anyone in your organization to access your content from anywhere they have an internet connection. Oxygen XML Web Author is highly versatile and can be customized to work with any XML vocabulary, most file repository systems, and virtually any type of workflow.

Web Author Integration and Customization

For detailed information about integrating and customizing Web Author, see the *Oxygen XML Web Author Customization Guide*.

Using Web Author

For information about using the Web Author product, see the *Oxygen XML Web Author User Manual*.

Feature Matrix

Oxygen XML Web Author was designed to provide the functionality of the **Author** mode in Oxygen XML Editor/Author in a mobile-friendly platform and can be embedded either in a third-party standalone Java application or customized as a Java Web Applet to provide WYSIWYG-like XML editing and reviewing directly in your choice of web browsers on your mobile devices or desktops.

Table 79: Feature Matrix Showing Differences Between Web Author and Oxygen XML Editor/Author

Intended audience	Reviewers and occasional contributors.	Content authors, technical writers.
Mobile device friendly	Specifically designed for mobile devices.	No
Compatibility with the standard versions of Oxygen	Covers only editing and reviewing features.	100%
Author mode	Yes	Yes
Text mode	Yes	Yes
Grid mode	No	Yes
Schema **Design** mode	No	Yes
Client-side setup	Yes, with an *Administration* page.	Requires Java to be installed, and Java Applets to be allowed to run.
Server-side setup	Requires running an installer or a servlet (along with performing a Maven build).	Requires a web server.

Add-ons

17

Topics:

- *CGM Image Support Add-on*
- *DocBook Checker Add-on*
- *Excel XLSX Libraries Add-on*
- *Git Support Add-on*
- *Saxon XSLT and XQuery Transformer Add-on*
- *Translation Package Builder Add-on*

Oxygen XML Editor offers various default *add-ons* that can be installed to provide additional functionality to Oxygen XML Editor. This chapter contains information about the default add-ons that are available to install directly from Oxygen XML Editor.

To install one of the default add-ons, follow this procedure:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select the add-on you want to install and click **Next**.
4. Restart the application.

CGM Image Support Add-on

Oxygen XML Editor offers two add-ons that provide experimental support for CGM 1.0 images. To allow the rendering of CGM images in **Author** mode, follow this procedure:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select the **Oxygen CGM support** add-on and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

   Result: You should be able to see CGM images in **Author** mode.

For more information, see the *details about this **CGM Support** add-on in GitHub*.

Alternate Method Using the ISOView Active X Component

Restriction: This support will only work on 32 bit versions of Oxygen XML Editor.

If you already have the *ISOView Active X* component for Internet Explorer installed, you may want to use it to render CGM images instead of the components provided in the plugin described above.

To use your existing *ISOView Active X* component to render CCM images, follow these steps:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select **CGM Form control (Active X-based)** plugin and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.

5. Restart the application.
6. The **CGM Form Control** plugin automatically renders CGM files in DITA, DocBook, and XHTML, so for those *frameworks*, this step is not necessary. For other *frameworks*, modify your CSS according to your particular *framework*.

   If you have an XML:

   ```
   <image href="MyCGMFile.cgm"/>
   ```

   You need a CSS rule like this:

   ```
   image[href$=".cgm"],
   image[href$=".CGM"]{
       content: oxy_editor(
                saHeavyFormControlClassName , "com.oxygenxml.activex.fctrl.ActiveXFormControl",
                href, oxy_url(oxy_base-uri() , attr(href)));
   }
   ```

   Result: After performing these steps, you should now be able to see CGM images in **Author** mode.

DocBook Checker Add-on

Oxygen XML Editor offers an add-on that allows you to validate DocBook files. It reports issues such as broken internal and external links, problems with images, or profiling conditions that conflict with profiling preferences.

To install it the add-on, follow these instructions:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select the **DocBook Checker** add-on and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

Result: A **Check DocBook for Completeness** action will now be available on the toolbar and in the contextual menu. This action opens a dialog box that offers various validation options and allows you to run a completeness check on the current DocBook document.

For more information, see the *details for this **DocBook Checker** add-on in GitHub*.

Excel XLSX Libraries Add-on

To import spreadsheet data from Excel 2007 or newer (`.xlsx`), Oxygen XML Editor needs additional libraries from the Apache POI project. Oxygen XML Editor offers an add-on that provides this support.

To add this support, follow this procedure:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select **Excel XLSX libraries** add-on and click **Next**.
4. Restart the application.

   Result: You can now use the ***Import** wizard* to import data from Excel 2007 or newer.

Related Information:

Exporting XML Content to Excel on page 533

Git Support Add-on

Oxygen XML Editor offers an add-on that contributes a built-in Git client directly into Oxygen XML Editor. Once this add-on is installed, a **Git Staging** view is available that includes various actions that perform common Git commands, such as *push*, *pull*, *change branch*, *commit*, and more. It also includes a built-in tool for comparing and merging changes.

To install it the add-on, follow these instructions:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select the **Git Support (Experimental)** add-on and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

Result: A **Git Staging** view will now be available in Oxygen XML Editor. This view acts as a basic Git client integrated directly into Oxygen XML Editor and it provides support for committing changes to a Git repository, comparing and merging changes, and other Git commands.

For more information, see the *details for this **Git Support** add-on in GitHub*.

Saxon XSLT and XQuery Transformer Add-on

Oxygen XML Editor offers an add-on that installs an external Saxon XSLT and XQuery processor and allows you to validate and transform XSLT and XQuery documents with that external processor. The default add-on update site includes both a Saxon 9.7 and 9.8 version of the add-on.

To install it the add-on, follow these instructions:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select either the **Saxon 9.7 XSLT and XQuery Transformer** or **Saxon 9.8 XSLT and XQuery Transformer** add-on and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

Result: When you configure the validation or transformation scenario, you will now have the option to choose the particular Saxon transformer.

Restriction: Debugging XSLT/XQuery transformations based on this engine is **NOT** supported.

Translation Package Builder Add-on

Oxygen XML Editor offers an add-on that contributes contextual menu actions that help you build a translation package for DITA files that can be sent to translators. You can also extract the changed files back into your project once you receive the package back from the translators.

To install it the add-on, follow these instructions:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select the **Translation Package Builder** add-on and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

Result: A **Tranlation Package Builder** submenu will now be available in the contextual menu of the **DITA Maps Manager**. This submenu includes actions to generate a package of modified files that can be sent to translators, as well as an action to extract translated files back into your DITA project.

For more information, see the *details for this **Translation Package Builder** add-on in GitHub*.

- *Compare Directories Against a Base (3-Way)*
- *Syncro SVN Client*
- *External Tools*

Oxygen XML Editor includes a variety of helpful tools to help you accomplish XML-related tasks. This section presents many of those tools. These tools are available in the **Tools** menu and some of them can be launched through keyboard shortcuts or command-line scripts.

Refactoring XML Documents

In the life cycle of XML documents there are instances when the XML structure needs to be changed to accommodate various needs. For example, when an associated schema is updated, an attribute may have been removed, or a new element added to the structure.

These types of situations cannot be resolved with a traditional *Find/Replace* tool, even if the tool accepts regular expressions. The problem becomes even more complicated if an XML document is computed or referenced from multiple modules, since multiple resources need to be changed.

To assist you with these types of refactoring tasks, Oxygen XML Editor includes a specialized **XML Refactoring** tool that helps you manage the structure of your XML documents.

XML Refactoring Tool

The **XML Refactoring** tool is presented in the form of an easy to use wizard that is designed to reduce the time and effort required to perform various structure management tasks. For example, you can insert, delete, or rename an attribute in all instances of a particular element that is found in all documents within your project.

To access the tool, select the **XML Refactoring** action from one of the following locations:

- The **Tools** menu.
- The **Refactoring** submenu from the contextual menu in the ***Project*** *view*.
- The **Refactoring** submenu from the contextual menu in the ***DITA Maps Manager*** *view*.

Note: The predefined refactoring operations are also available from the **Refactoring** submenu in the contextual menu of **Author** or **Text** mode. This is useful because by selecting the operations from the contextual menu, Oxygen XML Editor considers the editing context to skip directly to the wizard page of the appropriate operation and to help you by preconfiguring some of the parameter values. For your convenience, the last 5 operations that were *finished* or *previewed* also appear in the **Refactoring** submenu of the contextual menu in the **Project** view and the **DITA Maps Manager**.

XML Refactoring Wizard

The XML Refactoring tool includes the following wizard pages:

Refactoring operations

The first wizard page presents the available operations, grouped by category. To search for an operation, you can use the filter text box at the top of the page.

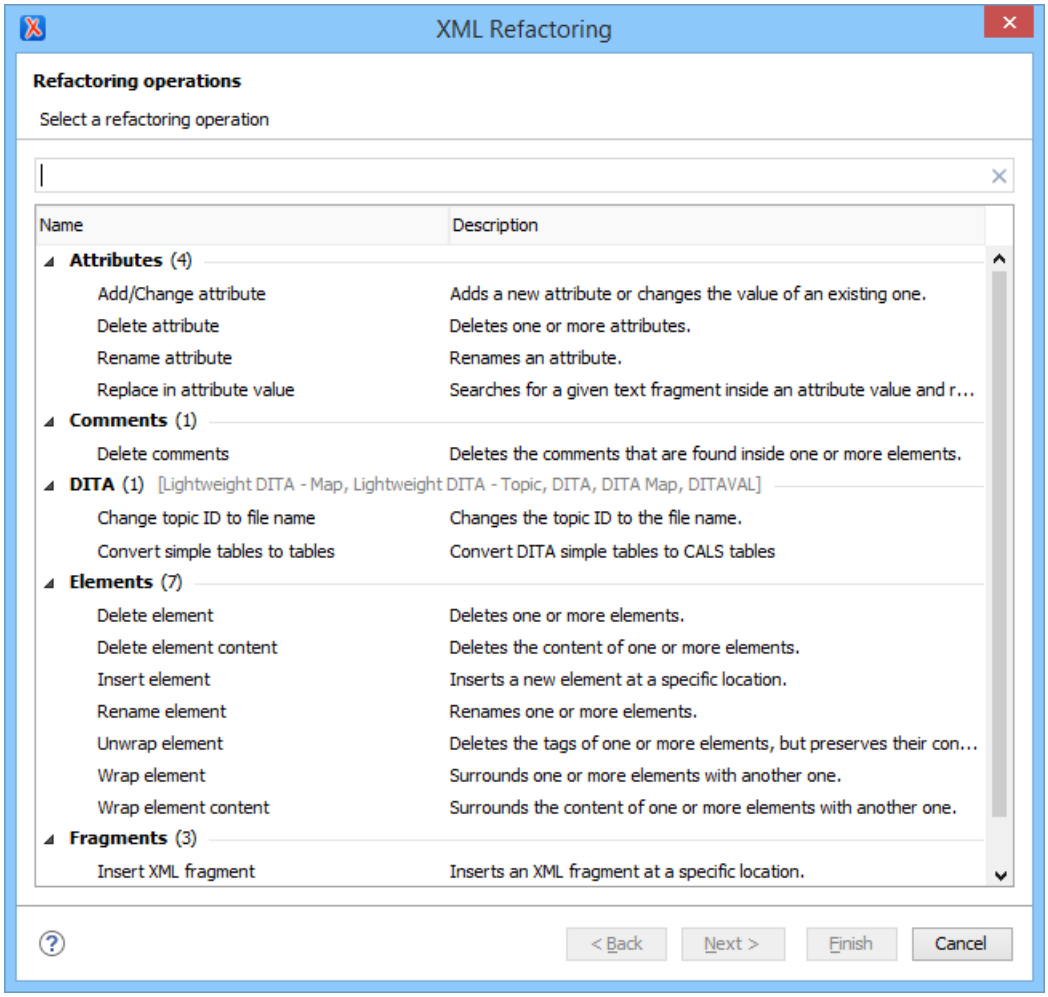

Figure 741: XML Refactoring Wizard

Configure Operation Parameters

The next wizard page allows you to specify the parameters for the refactoring operation. The parameters are specific to the type of refactoring operation that is being performed. For example, to delete an attribute you need to specify the parent element and the qualified name of the attribute to be removed.

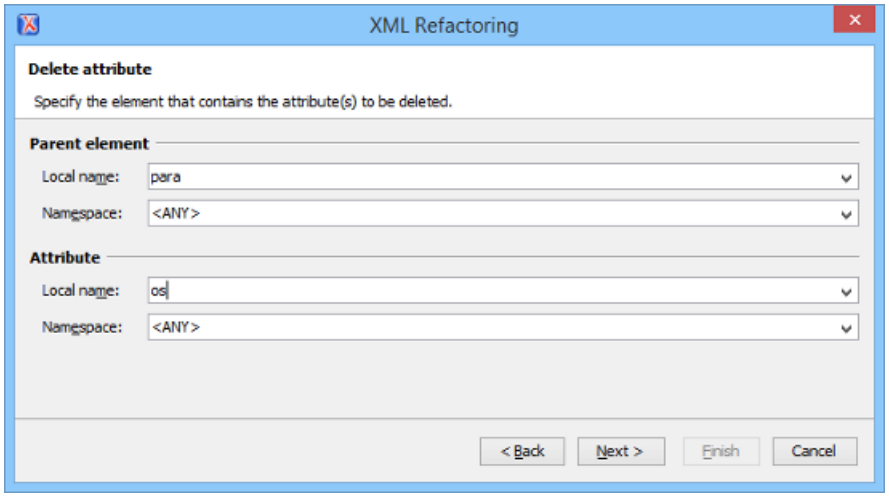

Figure 742: XML Refactoring 2nd Wizard Page (Delete Attribute Operation)

Scope and Filters

The last wizard page allows you to select the set of files that represent the input of the operation.

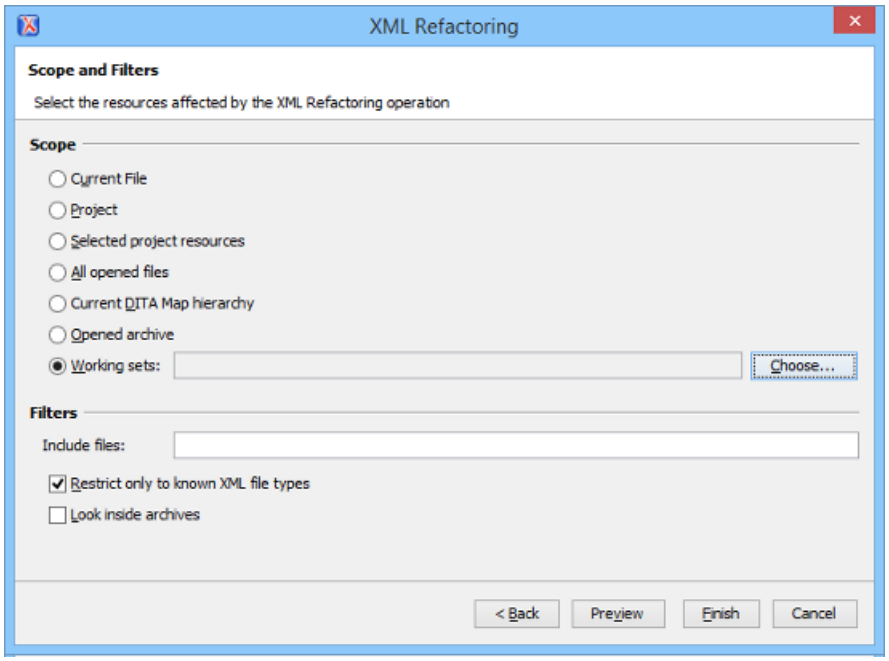

Figure 743: XML Refactoring - Scope and Filters Wizard Page

Scope section

In the **Scope** section, you can select from predefined resource sets (such as the current file, your whole project, the current *DITA map* hierarchy for DITA projects, etc.) or you can define your own set of resources by creating a *working set*.

Filters

The **Filters** section includes the following options:

- **Include files** - Allows you to filter the selected resources by using a file pattern. For example, to restrict the operation to only analyze build files you could use `build*.xml` for the file pattern.

- **Restrict only to known XML file types** - When selected, only resources with a known XML file type will be affected by the operation.
- **Look inside archives** - When selected, the resources inside archives will also be affected.

Preview

You can use the **Preview** button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

Finish

After clicking the **Finish** button, the operation will be processed and Oxygen XML Editor provides no automatic means for reverting the operations. Any **Undo** action will only revert changes on the current document.

Trouble: If an operation fails, a notification will be displayed in the **Results** panel with some information about the error. For example, if the operation was invoked on a read-only resource, the error will indicate that a read-only file cannot be converted.

Tip: If an operation takes longer than expected you can use the **Stop** button in the progress bar to cancel the operation.

Predefined Refactoring Operations

The XML Refactoring tool includes a variety of predefined operations that can be used for common refactoring tasks. They are grouped by category in the **Refactoring operations** wizard page. You can also access the operations from the **Refactoring** submenu in the contextual menu of **Author** or **Text** mode. The operations are also grouped by category in this submenu. When selecting the operations from the contextual menu, Oxygen XML Editor considers the editing context to get the names and namespaces of the current element or attribute, and uses this information to preconfigure some of the parameter values for the selected refactoring operation.

Tip: Each operation includes a link in the lower part of the wizard that opens the **XML / XSLT-FO-XQuery / XPath** preferences page where you can configure XPath options and declare namespace prefixes.

The following predefined operations are available:

Refactoring Operations for *Attributes*

Add/Change attribute

Use this operation to change the value of an attribute or insert a new one. This operation allows you to specify the following parameters:

- **Parent element** section
  - **Element** - The parent element of the attribute to be changed, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.
- **Attribute** section
  - **Local name** - The local name of the affected attribute.
  - **Namespace** - The namespace of the affected attribute.
  - **Value** - The value for the affected attribute.
- **Options** section
  - You can choose between one of the following options for the **Operation mode**:
    - **Add the attribute in the parent elements where it is missing**
    - **Change the value in the parent elements where the atrribute already exists**
    - **Both**

Convert attribute to element

Use this operation to convert a specified attribute to an element. This operation allows you to specify the following parameters:

- **Parent element** section

    - **Element** - The parent element of the attribute to be converted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.
- **Attribute** section
    - **Local name** - The local name of the affected attribute.
    - **Namespace** - The namespace of the affected attribute.
- **New element** section
    - **Local name** - The local name of the new element.
    - **Namespace** - The namespace of the new element.

Delete attribute

Use this operation to remove one or more attributes. This operation requires you to specify the following parameters:

- **Element** - The parent element of the attribute to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.
- **Attribute** - The name of the attribute to be deleted.

Rename attribute

Use this operation to rename an attribute. This operation requires you to specify the following parameters:

- **Element** - The parent element of the attribute to be renamed, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.
- **Attribute** - The name of the attribute to be renamed.
- **New local name** - The new local name of the attribute.

Replace in attribute value

Use this operation to search for a text fragment inside an attribute value and change the fragment to a new value. This operation allows you to specify the following parameters:

- **Target attribute** section
    - **Element** - The parent element of the attribute to be modified, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.
    - **Attribute** - The name of the attribute to be modified.
- **Find / Replace** section
    - **Find** - The text fragments to find. You can use Perl-like regular expressions.
    - **Replace with** - The text fragment to replace the target with. This parameter can bind regular expression capturing groups ($1 , $2, etc.) from the find pattern.

Refactoring Operations for *Comments*

Delete comments

Use this operation to delete comments from one or more elements. This operation requires you specify the following parameter:

- **Element** - The target element (or elements) for which comments will be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Note: Comments that are outside the root element will not be deleted because the *serializer* preserves the content before and after the root.

Refactoring Operations for *DITA*

Change topic ID to file name

Use this operation to change the ID of a topic to be the same as its file name.

Convert conrefs to conkeyrefs

Use this operation to convert `conref` attributes to `conkeyref` attributes. For more information and instructions for using this operation, see *Converting Conrefs to Conkeyrefs* on page 1863.

Convert simple tables to CALS tables

Use this operation to convert DITA simple tables to CALS tables.

Convert to Concept

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept). For more information, see *Converting DITA Topics to Another Type* on page 1826.

Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). For more information, see *Converting DITA Topics to Another Type* on page 1826.

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference). For more information, see *Converting DITA Topics to Another Type* on page 1826.

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task). For more information, see *Converting DITA Topics to Another Type* on page 1826.

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic). For more information, see *Converting DITA Topics to Another Type* on page 1826.

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting). For more information, see *Converting DITA Topics to Another Type* on page 1826.

All of these DITA refactoring actions allow you to choose a scope for the operation and some filters:

- **Scope** - Select from a variety of options to define the scope for which resources will be affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, **Current DITA map hierarchy**, or just the **Current file**.
- **Filters** section
  - **Include files** - Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).
  - **Restrict to known XML file types only** - Excludes non-XML file types from the operation.
  - **Look inside archives** - If this option is selected, the scope of the operation will include files inside archives.

Refactoring Operations for *Elements*

Delete element

Use this operation to delete elements. This operation requires you to specify the following parameter:

- **Element** - The target element to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Delete element content

Use this operation to delete the content of elements. This operation requires you to specify the following parameter:

- **Element** - The target element whose content is to be deleted, in the form of a local name from any namespace, a local name with a namespace prefix, or an XPath expression.

Insert element

Use this operation to insert new elements. This operation allows you to specify the following parameters:

- **Element** section
  - **Local name** - The local name of the element to be inserted.
  - **Namespace** - The namespace of the element to be inserted.
- **Location** section

- **XPath**- An XPath expression that identifies an existing element to which the new element is relative, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.
- **Position** - The position where the new element will be inserted, in relation to the specified existing element. The possible selections in the drop-down menu are: **After**, **Before**, **First child**, or **Last child**.

Rename element

Use this operation to rename elements. This operation requires you to specify the following parameters:

- **Target elements (XPath)** - The target elements to be renamed, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.
- **New local name** - The new local name of the element.

Unwrap element

Use this operation to remove the surrounding tags of elements, while keeping the content unchanged. This operation requires you to specify the following parameter:

- **Target elements (XPath)** - The target elements whose surrounding tags will be removed, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

Wrap element

Use this operation to surround elements with element tags. This operation allows you to specify the following parameters:

- **Target elements (XPath)** - The target elements to be surrounded with tags, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.
- **Wrapper element** section
  - **Local name** - The local name of the *Wrapper element*.
  - **Namespace** - The namespace of the *Wrapper element*.

Wrap element content

Use this operation to surround the content of elements with element tags. This operation allows you to specify the following parameters:

- **Target elements (XPath)** - The target elements whose content will be surrounded with tags, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.
- **Wrapper element** section
  - **Local name** - The local name of the *Wrapper element* that will surround the content of the target.
  - **Namespace** - The namespace of the *Wrapper element* that will surround the content of the target.

Refactoring Operations for *Fragments*

Insert XML fragment

Use this operation to insert an XML fragment. This operation allows you to specify the following:

- **XML Fragment** - The XML fragment to be inserted.
- **Location** section
  - **XPath** - An XPath expression that identifies an existing element to which the inserted fragment is relative, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.
  - **Position** - The position where the fragment will be inserted, in relation to the specified existing element. The possible selections in the drop-down menu are: **After**, **Before**, **First child**, or **Last child**.

Replace element content with XML fragment

Use this operation to replace the content of elements with an XML fragment. This operation allows you to specify the following parameters:

- **Target elements (XPath)** - The target elements whose content will be replaced, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.

- **XML Fragment** - The XML fragment with which to replace the content of the target element.

Replace element with XML fragment

Use this operation to replace elements with an XML fragment. This operation allows you to specify the following parameters:

- **Target elements (XPath)** - The target elements to be replaced, in the form of a local name from any namespace, a local name with a namespace prefix, or other XPath expressions.
- **XML Fragment** - The XML fragment with which to replace the target element.

Refactoring Operations for *JATSKit*

Add BITS DOCTYPE - NLM/NCBI Book Interchange 2.0

Use this operation to add an NLM 'BITS' 2.0 DOCTYPE declaration.

Add Blue DOCTYPE - NISO JATS Publishing 1.1

Use this operation to add a JATS 'Blue' 1.1 DOCTYPE declaration.

Normalize IDs

Use this operation to normalize assigned IDs and assigned IDs to elements that are missing them.

All of these JATSKit refactoring actions allow you to choose a scope for the operation and some filters:

- **Scope** - Select from a variety of options to define the scope for which resources will be affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, or just the **Current file**.
- **Filters** section
  - **Include files** - Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).
  - **Restrict to known XML file types only** - Excludes non-XML file types from the operation.
  - **Look inside archives** - If this option is selected, the scope of the operation will include files inside archives.

Additional Notes

Note: There are some operations that allow <ANY> for the **local name** and **namespace** parameters. This value can be used to select an element or attribute regardless of its local name or namespace. Also, the <NO_NAMESPACE> value can be used to select nodes that do not belong to a namespace.

Note: Some operations have parameters that accept XPath expressions to match elements or attributes. In these XPath expressions you can only use the prefixes declared in the ***Options*** > ***Preferences*** > ***XML*** > ***XSLT-FO-XQUERY*** > ***XPath*** page. This preferences page can be easily opened by clicking the link in the note (**Each prefix used in an XPath expression must be declared in the Default prefix-namespace mappings section**) at the bottom of the **Configure Operation Parameters** wizard page.

Custom Refactoring Operations

While Oxygen XML Editor includes a variety of predefined XML refactoring operations to help you accomplish particular tasks, you can also create custom operations according to your specific needs. For example, you could create a custom refactoring operation to convert an attribute to an element and insert the element as the first child of the parent element.

An XML Refactoring operation is defined as a pair of resources:

- An *XQuery Update script* or *XSLT stylesheet* that Oxygen XML Editor will run to refactor the XML files.
- An *XML Operation Descriptor* file that contains information about the operation (such as the name, description, and parameters).

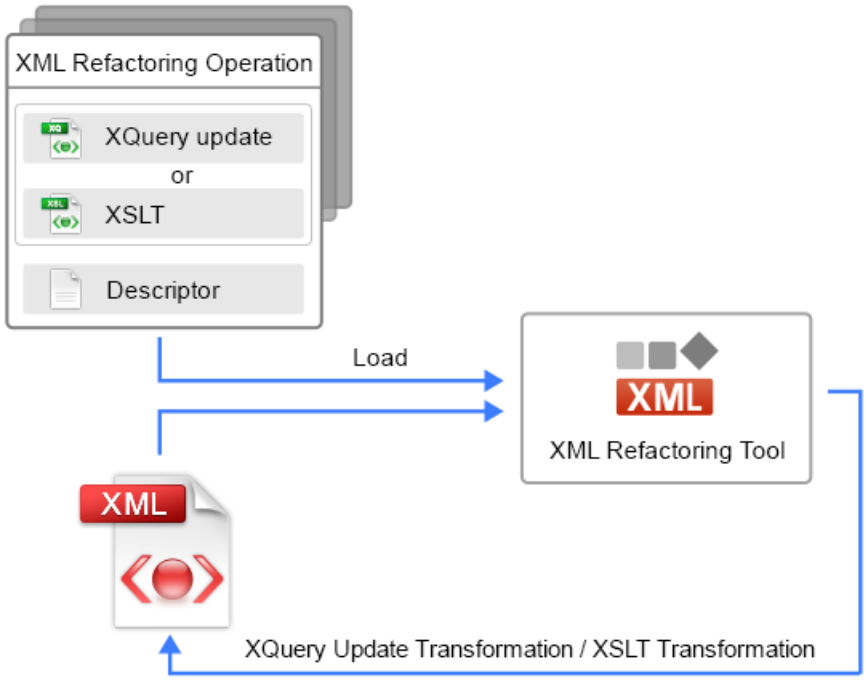

Figure 744: Diagram of an XML Refactoring Operation

All the defined custom operations are loaded by the **XML Refactoring Tool** and presented in *the **Refactoring Operations** wizard page*, along with the predefined built-in operations.

After the user chooses an operation and specifies its parameters, Oxygen XML Editor processes an XQuery Update or XSLT transformation over the input file. This transformation is executed in a **safe mode**, which implies the following:

- When loading the document:
  - The **XInclude** mechanism is disabled. This means that the resources included by using XInclude will not be visible in the transformation.
  - The DTD entities will be processed without being expanded.
  - The associated DTD will be not loaded, so the default attributes declared in the DTD will not be visible in the transformation.
- When saving the updated XML document:
  - The DOCTYPE will be preserved.

    Note: This can be changed using *Saxon extension functions in XSLT*.
  - The DTD entities will be preserved as they are in the original document when the document is saved.
  - The attribute values will be kept in their original form without being normalized.
  - The spaces between attributes are preserved. Basically, the spaces are lost by a regular XML serialization since they are not considered important.

The result of this transformation overrides the initial input file.

Note: To achieve some of the previous goals, the XML Refactoring mechanism adds several attributes that are interpreted internally. The attributes belong to the `http://www.oxygenxml.com/ns/xmlRefactoring/additional_attributes` namespace. These attributes should not be taken into account when processing the input XML document since they are discarded when the transformed document is serialized.

Restriction: *Comments* or *processing instructions* that are in any node before or after the root element cannot be modified by an XML Refactoring operation. In other words, XML Refactoring operations can only be applied on the root element and the nodes inside it. However, as a work around to this limitation, you can use *Saxon extension functions and the XSLT stylesheet method* to implement the new custom XML refactoring operation.

Creating a Custom Refactoring Operation

To create a custom refactoring operation, follow these steps:

1. Create an *XQuery Update script* or *XSLT stylesheet file*.
2. Create an **XML Refactoring Operation Descriptor** file contains the path to the *XQuery Update script* or *XSLT stylesheet*.
3. Store both files in *one of the locations that Oxygen XML Editor* scans when loading the custom operations.

   Result: Once you run the **XML Refactoring** tool again, the custom operation appears in *the **Refactoring Operations** wizard page*.

Related Information:

Storing and Sharing Refactoring Operations on page 721

Custom Refactoring Script

The first step in creating a custom refactoring operation is to create an *XQuery Update script* or *XSLT stylesheet* that is needed to process the refactoring operations. The easiest way to create this script file is to use the **New** document wizard to create a new **XQuery** or **XSLT** file and you can use our *XQuery method example* or *XSLT method example* to help you with the content.

There are cases when it is necessary to add parameters in the *XQuery script* or *XSLT stylesheet*. For instance, if you want to rename an element, you may want to declare an external parameter associated with the name of the element to be renamed. To allow you to specify the value for these parameters, they need to be declared in the *refactoring operation descriptor file* that is associated with this operation.

Note: The XQuery Update processing is disabled by default in Oxygen XML Editor. Thus, if you want to create or edit an XQuery Update script you have to enable this mechanism by creating an *XQuery transformation scenario* and choose **Saxon EE** as the transformation engine. Also, you need to make sure the ***Enable XQuery update** option is selected in the Saxon processor advanced options*.

Note: If you are using an XSLT file, XPath expressions that are passed as parameters will automatically be rewritten to conform with the mapping of the namespace prefixes declared in the ***XML /XSLT-FO-XQuery / XPath** preferences page*.

The next step in creating a custom refactoring operation is to create an **XML Refactoring Operation Descriptor** file contains the path to the *XQuery Update script* or *XSLT stylesheet*.

Related Information:

XQuery Update Script for Creating a Custom Operation on page 714
XSLT Stylesheet for Creating a Custom Operation on page 717

Custom Refactoring Operation Descriptor File

The second step in creating a custom refactoring operation is to create an operation descriptor file. The easiest way to do this is to use the **New** document wizard and choose the **XML Refactoring Operation Descriptor** template.

Introduction to the Descriptor File

This file contains information (such as `name`, `description`, and `id`) that is necessarily when loading an XML Refactoring operation . It also contains the path to the *XQuery Update script* or *XSLT stylesheet* that is associated with the particular operation through the `script` element.

You can specify a `category` for your custom operations to logically group certain operations. The `category` element is optional and if it is not included in the descriptor file, the default name of the category for the custom operations is *Other operations*.

The descriptor file is edited and validated against the following schema: `frameworks/xml_refactoring/operation_descriptor.xsd`.

Declaring Parameters in the Descriptor File

If the XQuery Update script or XSLT stylesheet includes parameters, they should be declared in the **parameters** section of the descriptor file. All the parameters specified in this section of the descriptor file will be displayed in the **XML Refactoring** tool within *the **Configure Operation Parameters** wizard page* for that particular operation.

The value of the first `description` element in the **parameters** section will be displayed at the top of *the **Configure Operation Parameters** wizard page*.

To declare a parameter, specify the following information:

- **`label`** - This value is displayed in the user interface for the parameter.
- **`name`** - The parameter name used in the XQuery Update script or XSLT stylesheet and it should be the same as the one declared in the script.
- **`type`** - Defines the type of the parameter and how it will be rendered. There are several types available:
  - `TEXT` - Generic type used to specify a simple text fragment.
  - `XPATH` - Type of parameter whose value is an XPATH expression. For this type of parameter, Oxygen XML Editor will use a text input with corresponding content completion and syntax highlighting.

    Note: The value of this parameter is transferred as plain text to the XQuery Update or XSLT transformation without being evaluated. You should evaluate the XPath expression inside the XQuery Update script or XSLT stylesheet. For example, you could use the `saxon:evaluate` Saxon extension function.

    Note: A relative XPath expression is converted to an absolute XPath expression by adding `//` before it (`//XPathExp`). This conversion is done before transferring the XPath expression to the XML refactoring engine.

    Note: When writing XPath expressions, you can only use prefixes declared in the ***Options*** > ***Preferences*** > ***XML*** > ***XSLT-FO-XQUERY*** > ***XPath*** options page.
  - `NAMESPACE` - Used for editing namespace values.
  - `REG_EXP_FIND` - Used when you want to match a certain text by using Perl-like regular expressions.
  - `REG_EXP_REPLACE` - Used along with `REG_EXP_FIND` to specify the replacement string.
  - `XML_FRAGMENT` - This type is used when you want to specify an XML fragment. For this type, Oxygen XML Editor will display a text area specialized for inserting XML documents.
  - `NC_NAME` - The parameter for `NC_NAME` values. It is useful when you want to specify the local part of a *QName* for an element or attribute.
  - `BOOLEAN` - Used to edit boolean parameters.
  - `TEXT_CHOICE` - It is useful for parameters whose value should be from a list of possible values. Oxygen XML Editor renders each possible value as a radio button option.
- **`description`** - The description of the parameter. It is used by the application to display a tooltip when you hover over the parameter.
- **`possibleValues`** - Contains the list with possible values for the parameter and you can specify the default value, as in the following example:

```
<possibleValues onlyPossibleValuesAllowed="true">
    <value name="before">Before</value>
    <value name="after"default="true">After</value>
    <value name="firstChild">First child</value>
    <value name="lastChild">Last child</value>
</possibleValues>
```

Specialized Parameters to Match Elements or Attributes

If you want to match elements or attributes, you can use some specialized parameters, in which case Oxygen XML Editor will propose all declared elements or attributes based on the schema associated with the currently edited file. The following specialized parameters are supported:

`elementLocation`

This parameter is used to match elements. For this type of parameter, the application displays a text field where you can enter the element name or an XPath expression. The text from the `label` attribute is displayed in the application as the label of the text field. The `name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. If the value of the `useCurrentContext`

attribute is set to **true**, the element name from the cursor position is used as proposed values for this parameter.

Example of an `elementLocation`:

```
<elementLocation name="elem_loc" useCurrentContext="false">
                <element label="Element location">
                    <description>Element location description.</description>
                </element>
</ ElementLocation>
```

`attributeLocation`

This parameter is used to match attributes. For this type of parameter, the application displays two text fields where you can enter the parent element name and the attribute name (both text fields accept XPath expressions for a finer match). The text from the `label` attributes is displayed in the application as the label of the associated text fields. The `name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. The value of this parameter is an XPath expression that is computed by using the values of the expression from the `element` and `attribute` text fields. For example, if `section` is entered for the element and a `title` is entered for the attribute, the XPath expression would be computed as `//section/@title`. If the value of the `useCurrentContext` attribute is set to `true`, the element and attribute name from the cursor position is used as proposed values for the operation parameters.

Example of an `attributeLocation`:

```
<attributeLocation name="attr_xpath" useCurrentContext="true">
                <element label="Element path">
                    <description>Element path description.</description>
                </element>
                <attribute label="Attribute" >
                    <description>Attribute path description.</description>
                </attribute>
</ AttributeLocation>
```

`elementParameter`

This parameter is used to specify elements by local name and namespace. For this type of parameter, the application displays two combo boxes with elements and namespaces collected from the associated schema of the currently edited file. The text from the `label` attribute is displayed in the application as label of the associated combo. The `name` attribute is used to specify the name of the parameter from the XQuery Update script or XSLT stylesheet. If you specify the `allowsAny` attribute, the application will propose *<ANY>* as a possible value for the **Name** and **Namespace** combo boxes. You can also use the `useCurrentContext` attribute and if its value is set to `true`, the element name and namespace from the cursor position is used as proposed values for the operation parameters.

Example of an `elementParameter`:

```
<elementParameter id="elemID" useCurrentContext="true">
    <localName label="Name" name="element_localName" allowsAny="true">
        <description>Local name of the parent element.</description>
    </localName>
    <namespace label="Namespace" name="element_namespace" allowsAny="true">
        <description>Local name of the parent element</description>
    </namespace>
</elementParameter>
```

`attributeParameter`

This parameter is used to specify attributes by local name and namespace. For this type of parameter, the application displays two combo boxes with attributes and their namespaces collected from the associated schema of the currently edited file. The text from the `label` attribute is displayed in the application as the label of the associated combo box. You can also use the `useCurrentContext` attribute and if its value is set to `true`, the attribute name and namespace from the cursor position is used as proposed values for the operation parameters.

Note: An `attributeParameter` is dependant upon an `elementParameter`. The list of attributes and namespaces are computed based on the selection in the `elementParameter` combo boxes.

Example of an `attributeParameter`:

```
<attributeParameter dependsOn="elemID" useCurrentContext="true">
```

```
    <localName label="Name" name="attribute_localName">
        <description>The name of the attribute to be converted.</description>
    </localName>
    <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
        <description>Namespace of the attribute to be converted.</description>
    </namespace>
</attributeParameter>
```

Note: All predefined operations are loaded from the *[OXYGEN_INSTALL_DIR]*`/refactoring` folder.

XSLT Stylesheet for Creating a Custom Operation

To demonstrate creating a custom operation, consider that we have a task where we need to convert an attribute into an element and insert it inside another element. A specific example would be if you have a project with a variety of `image` elements where a deprecated `alt` attribute was used for the description and you want to convert all instances of that attribute into an element with the same name and insert it as the first child of the `image` element.

Thus, our task is to convert this attribute into an element with the same name and insert it as the first child of the image element.

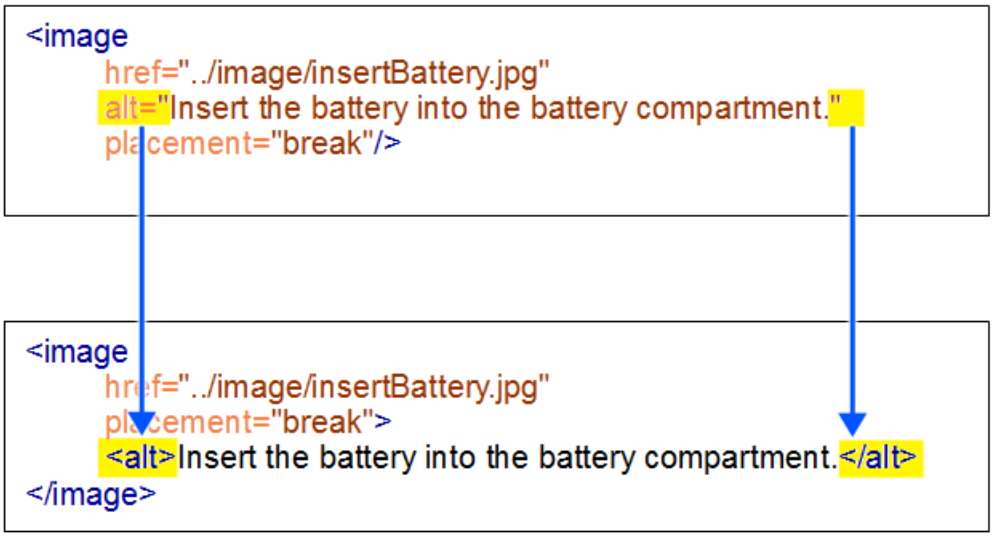

Figure 745: Example: Custom XML Refactoring Operation

We can use an XSLT stylesheet to implement the new custom XML refactoring operation. The second requirement is an *XML Refactoring operation descriptor file* that contains the path to the XSLT stylesheet.

Example of an XSLT Script for Creating a Custom Operation to *Convert an Attribute to an Element*

The XSLT stylesheet does the following:

- Iterates over all elements from the document that have the specified local name and namespace.
- Finds the attribute that will be converted to an element.
- Adds the new element as the first child of the parent element.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  exclude-result-prefixes="xs"
  xmlns:xr="http://www.oxygenxml.com/ns/xmlRefactoring"
  version="2.0">

  <xsl:import
href="http://www.oxygenxml.com/ns/xmlRefactoring/resources/commons.xsl"/>
```

```
   <xsl:param name="element_localName" as="xs:string" required="yes"/>
   <xsl:param name="element_namespace" as="xs:string" required="yes"/>
   <xsl:param name="attribute_localName" as="xs:string" required="yes"/>
   <xsl:param name="attribute_namespace" as="xs:string" required="yes"/>
   <xsl:param name="new_element_localName" as="xs:string" required="yes"/>
   <xsl:param name="new_element_namespace" as="xs:string" required="yes"/>

   <xsl:template match="node() | @*">
       <xsl:copy>
           <xsl:apply-templates select="node() | @*"/>
       </xsl:copy>
   </xsl:template>
   <xsl:template match="//*[xr:check-local-name($element_localName, ., true())
      and
         xr:check-namespace-uri($element_namespace, .)]">

       <xsl:variable name="attributeToConvert"
          select="@*[xr:check-local-name($attribute_localName, ., true())
      and
         xr:check-namespace-uri($attribute_namespace, .)]"/>

       <xsl:choose>
           <xsl:when test="empty($attributeToConvert)">
               <xsl:copy>
                   <xsl:apply-templates select="node() | @*"/>
               </xsl:copy>
           </xsl:when>
       <xsl:otherwise>
           <xsl:copy>
               <xsl:for-each select="@*[empty(. intersect $attributeToConvert)]">
                    <xsl:copy-of select="."/>
               </xsl:for-each>
                 <!-- The new element namespace -->
                 <xsl:variable name="nsURI" as="xs:string">
                     <xsl:choose>
            <xsl:when test="$new_element_namespace eq $xr:NO-NAMESPACE">
                         <xsl:value-of select="''"/>
                    </xsl:when>
                    <xsl:otherwise>
                        <xsl:value-of select="$new_element_namespace"/>
                    </xsl:otherwise>
                </xsl:choose>
              </xsl:variable>
           <xsl:element name="{$new_element_localName}" namespace="{$nsURI}">
                    <xsl:value-of select="$attributeToConvert"/>
              </xsl:element>
               <xsl:apply-templates select="node()"/>
          </xsl:copy>
        </xsl:otherwise>
      </xsl:choose>
   </xsl:template>
 </xsl:stylesheet>
```

Note: The XSLT stylesheet imports a module library that contains utility functions and variables. The location of this module is resolved via an *XML Catalog* set in the XML Refactoring *framework*.

Example of an Operation Descriptor File That References the XSLT Stylesheet for Creating a Custom Operation to *Convert an Attribute to an Element*

After you have developed the XSLT stylesheet, you have to create an XML Refactoring operation descriptor. This descriptor is used by the application to load the operation details such as name, description, or parameters.

```
<?xml version="1.0" encoding="UTF-8"?>

<refactoringOperationDescriptor
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns="http://www.oxygenxml.com/ns/xmlRefactoring"
 id="convert-attribute-to-element"
 name="Convert attribute to element">
 <description>Converts the specified attribute to an element.
           The new element will be inserted as first child of the attribute's
           parent element.</description>
 <!-- For the XSLT stylesheet option uncomment the following line and comment
           the line referring the XQuery Update script -->
 <!-- <script type="XSLT" href="convert-attribute-to-element.xsl"/> -->
 <script type="XQUERY_UPDATE" href="convert-attribute-to-element.xq"/>
  <parameters>
   <description>Specify the attribute to be converted to element.</description>
    <section label="Parent element">
     <elementParameter id="elemID">
      <localName label="Name" name="element_localName" allowsAny="true">
       <description>Local name of the parent element.</description>
        </localName>
       <namespace label="Namespace" name="element_namespace" allowsAny="true">
         <description>Local name of the parent element</description>
       </namespace>
     </elementParameter>
    </section>
    <section label="Attribute">
```

```
     <attributeParameter dependsOn="elemID">
      <localName label="Name" name="attribute_localName">
       <description>Name of the attribute to be converted.</description>
      </localName>
     <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
       <description>Namespace of the attribute to be converted.</description>
     </namespace>
     </attributeParameter>
    </section>
    <section label="New element">
        <elementParameter>
           <localName label="Name" name="new_element_localName">
               <description>The name of the new element.</description>
           </localName>
           <namespace label="Namespace" name="new_element_namespace">
               <description>The namespace of the new element.</description>
           </namespace>
        </elementParameter>
    </section>
  </parameters>
</refactoringOperationDescriptor>
```

Note: If you are using an XSLT file, the line with the `script` element would look like this:

```
<script type="XSLT" href="convert-attribute-to-element.xsl"/>
```

Results

After you have created these files, copy them into a folder *scanned by Oxygen XML Editor when it loads the custom operation*. When the XML Refactoring tool is started again, you will see the created operation.

Since various parameters can be specified, this custom operation can also be used for other similar tasks. The following image shows the parameters that can be specified in our example of the custom operation to convert an attribute to an element:

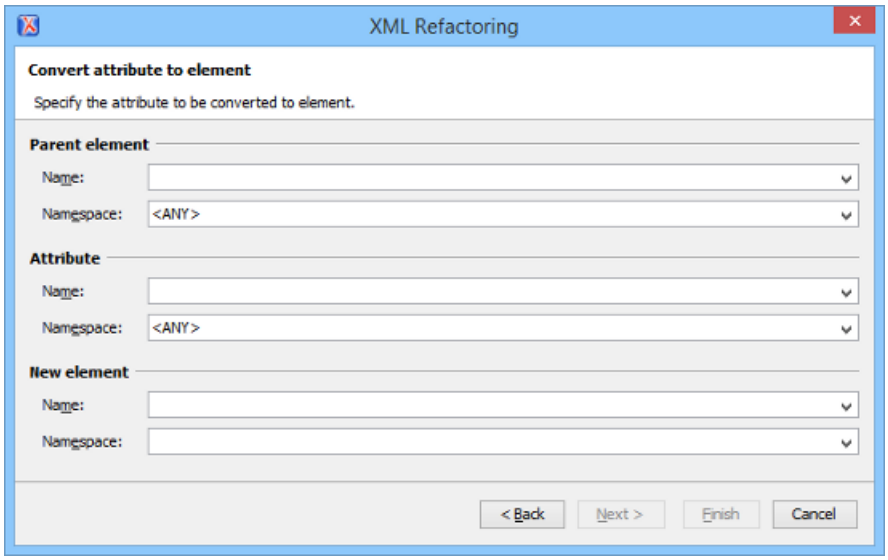

Figure 746: Example: XML Refactoring Wizard for a Custom Operation

Using Saxon Extension Functions to Allow Custom Refactoring Operations to Read and Modify Content Outside the Root Node

One advantage to using an XSLT stylesheet is that there is limitation when using an *XQuery Update script* in that refactoring operations can only be performed on *comments* or *processing instructions* that are inside the root element. Thus, using the XQuery method, *comments* or *processing instructions* that are in any node before or after the root element cannot be modified by an XML Refactoring operation.

The XSLT stylesheet method offers a work around to this limitation through the use of some Saxon extension functions.

To illustrate the use of these functions, consider the following sample XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- comment before root -->
```

```
<?pi before root ?>
<root>
    <child></child>
</root>
<!-- comment after root -->
<?pi after root ?>
```

The following Saxon extension functions can be used to read and modify content outside the root node:

Note: They belong to the `http://www.oxygenxml.com/ns/xmlRefactoring/functions` namespace.

- **get-content-after-root()** - Returns the content after root as `xs:string`.

  For the XML above, the call of this function will return the following string value:

  ```
  <!-- comment after root -->
  <?pi after root ?>
  ```

- **set-content-after-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

  The function call `set-content-after-root('<!-- Inserted comment -->')` will result in replacing the nodes after the root element with the comment passed as string argument. The XML document will be modified as follows:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <!-- comment before root -->
  <?pi before root ?>
  <root>
      <child></child>
  </root><!-- Inserted comment -->
  ```

- **get-content-before-root()** - Returns the content before root as `xs:string`.

  For the XML above, the call of this function will return the following string value:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <!-- comment before root -->
  <?pi before root ?>
  ```

- **set-content-before-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

  The function call `set-content-before-root('<!-- Inserted comment -->')` will result in replacing the nodes before the root element with the comment passed as string argument. The XML document will be modified as follows:

  ```
  <!-- Inserted comment --><root>
      <child></child>
  </root>
  <!-- comment after root -->
  <?pi after root ?>
  ```

XSLT Example:

To process content after the root node, the XSLT would look like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema" exclude-result-prefixes="xs"
    xmlns:xrf="http://www.oxygenxml.com/ns/xmlRefactoring/functions" version="3.0">
    <xsl:template match="/">
        <!-- The comment content that will be inserted after the root element -->
        <xsl:variable name="commentAsText">&lt;!-- COMMENT ADDED FROM XR OPERATION-->
        </xsl:variable>
        <!-- Retrieve the content after the root element as is -->
        <xsl:variable name="after-root-content" as="xs:string"
                      select="xrf:get-content-after-root()"/>

        <xsl:variable name="processedContent"
                      select="concat($after-root-content, $commentAsText)"/>

        <!-- Update the content after the root element -->
        <xsl:value-of select="xrf:set-content-after-root($processedContent)"/>

        <xsl:apply-templates/>
    </xsl:template>

    <xsl:template match="node() | @*">
        <xsl:copy>
```

```
            <xsl:apply-templates select="node() | @*"/>
        </xsl:copy>
    </xsl:template>
</xsl:stylesheet>
```

Note: The above XSLT retrieves the nodes after the root element as string, appends a new comment, and then sets back the updated content into the XML document.

Storing and Sharing Refactoring Operations

Oxygen XML Editor scans the following locations when looking for XML Refactoring operations to provide flexibility:

- A `refactoring` folder, created inside a directory that is associated to a *framework* you are customizing. To associate the parent directory to the *framework*, you need to add it in the ***Classpath*** *tab of the* ***Document type*** *configuration dialog box*.
- A folder that you specify in the ***Load additional refactoring operations from*** *text box* in the ***XML Refactoring*** *preferences page*.

  Note: If you share a project with your team, you can also share the custom operation by doing the following:

  1. Save the custom operation in a folder that is part of your project.
  2. Switch the **XML Refactoring** option page to *project level*:
     a. *Open the* ***Preferences*** *dialog box* ***(Options*** > ***Preferences)*** and go to ***XML*** > ***XML Refactoring***.
     b. Select ***Project Options*** at the bottom of the dialog box.
  3. In the ***Load additional refactoring operations from*** *text box*, use the *${pd} editor variable* so that the folder path is declared relative to the project.
- A folder specified by the *XML Refactoring Operations Plugin Extension*.
- The `refactoring` folder from the Oxygen XML Editor installation directory (*`[OXYGEN_INSTALL_DIR]`*`/refactoring/`).

Sharing Custom Refactoring Operations

The purpose of Oxygen XML Editor scanning multiple locations for the XML Refactoring operations is to provide more flexibility for developers who want to share the refactoring operations with the other team members. Depending on your particular use case, you can attach the custom refactoring operations to other resources, such as *framework* or projects.

After storing custom operations, you can share them with other users by sharing the resources.

Localizing XML Refactoring Operations

Oxygen XML Editor includes localization support for the XML refactoring operations.

The translation keys for the built-in refactoring operations are located in *`[OXYGEN_INSTALL_DIR]`*`/refactoring/i18n/translation.xml`.

The localization support is also available for custom refactoring operations. The following information can be translated:

- The operation `name`, `description`, and `category`.
- The `description` of the `parameters` element.
- The `label`, `description`, and `possibleValues` for each `parameter`.

Translated refactoring information uses the following form:

```
${i18n(translation_key)}
```

Oxygen XML Editor scans the following locations to find the `translation.xml` files that are used to load the translation keys:

- A `refactoring/i18n` folder, created inside a directory that is associated to a customized *framework*.
- A `i18n` folder, created inside a directory that is associated to a customized *framework*.

- An `i18n` folder inside any specified folder. In this case, you need to *open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **XML** > **XML Refactoring**, and specify the folder in the **Load additional refactoring operations from** text box.
- An `i18n` folder located in directories specified through the *XML Refactoring Operations Plugin Extension*.
- The `refactoring/i18n` folder from the Oxygen XML Editor installation directory (*`[OXYGEN_INSTALL_DIR]`*`/refactoring/i18n`).

Example: Refactoring Operation Descriptor File with *i18n* Support

```
<?xml version="1.0" encoding="UTF-8"?>

<refactoringOperationDescriptor
    xmlns="http://www.oxygenxml.com/ns/xmlRefactoring" id="remove_text_content"
          name="${i18n(Remove_text_content)}">
    <description>${i18n(Remove_text_content_description)}</description>
    <script type="XQUERY_UPDATE" href="remove_text_content.xq"/>
    <parameters>
        <description>${i18n(parameters_description)}</description>
        <parameter label="${i18n(Element_name)}" name="element_localName"
                    type="NC_NAME">
            <description>${i18n(Element_name_descriptor)}</description>
            <possibleValues>
                <value default="true" name="value1">${i18n(value_1)}</value>
                <value name="value2">${i18n(value_2)}</value>
            </possibleValues>
        </parameter>
    </parameters>
</refactoringOperationDescriptor>
```

Generating Sample XML Files

Oxygen XML Editor offers support to generate sample XML files both from XML schema 1.0 and XML schema 1.1, depending on the XML schema version set in ***XML Schema** preferences page*.

To generate sample XML files from an XML Schema, use the **Generate Sample XML Files** action from the **Tools** menu. This action is also available in the contextual menu of the schema *Design mode*. The action opens the **Generate Sample XML Files** dialog box that allows you to configure a variety of options for generating the files.

The **Generate Sample XML Files** dialog box contains three tabs with various configurable options. Default values for these options can be set in the ***Sample XML Files Generator** preferences page*. You can also run the tool from the command line using exported options.

Schema Tab (Generate Sample XML Files Tool)

The **Generate Sample XML Files** tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The first set of options are found in the **Schema** tab.

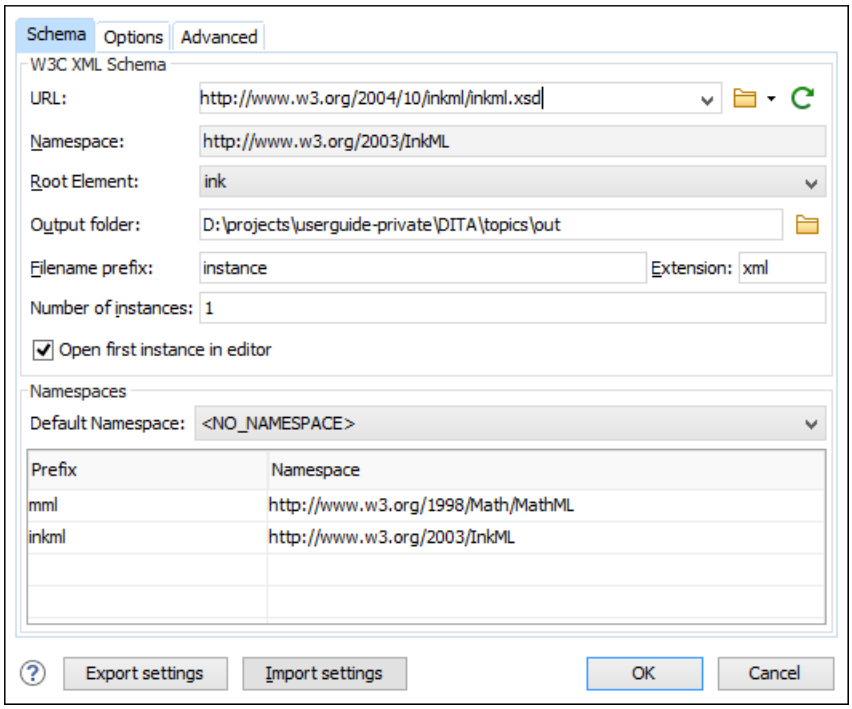

Figure 747: Generate Sample XML Files Dialog Box (Schema Tab)

This tab includes the following options:

URL

Specifies the URL of the Schema location. You can specify the path by using the text field, the history drop-down menu, or the browsing tools in the **Browse** drop-down list.

Namespace

Displays the namespace of the selected schema.

Root Element

After the schema is selected, this drop-down menu is populated with all root candidates gathered from the schema. Choose the root of the output XML documents.

Output folder

Path to the folder where the generated XML instances will be saved.

Filename prefix and Extension

You can specify the prefix and extension for the file name that will be generated. Generated file names have the following format: `prefixN.extension`, where N represents an incremental number from 0 up to the specified ***Number of instances***.

Number of instances

The number of XML files to be generated.

Open first instance in editor

When selected, the first generated XML file is opened in the editor.

Namespaces section

You can specify the **Default Namespace**, as well as the prefixes for the namespaces.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

You can click **OK** at any point to generate the sample XML files.

Options Tab (Generate Sample XML Files Tool)

The **Generate Sample XML Files** tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The **Options** tab allows you to set specific options for namespaces and elements.

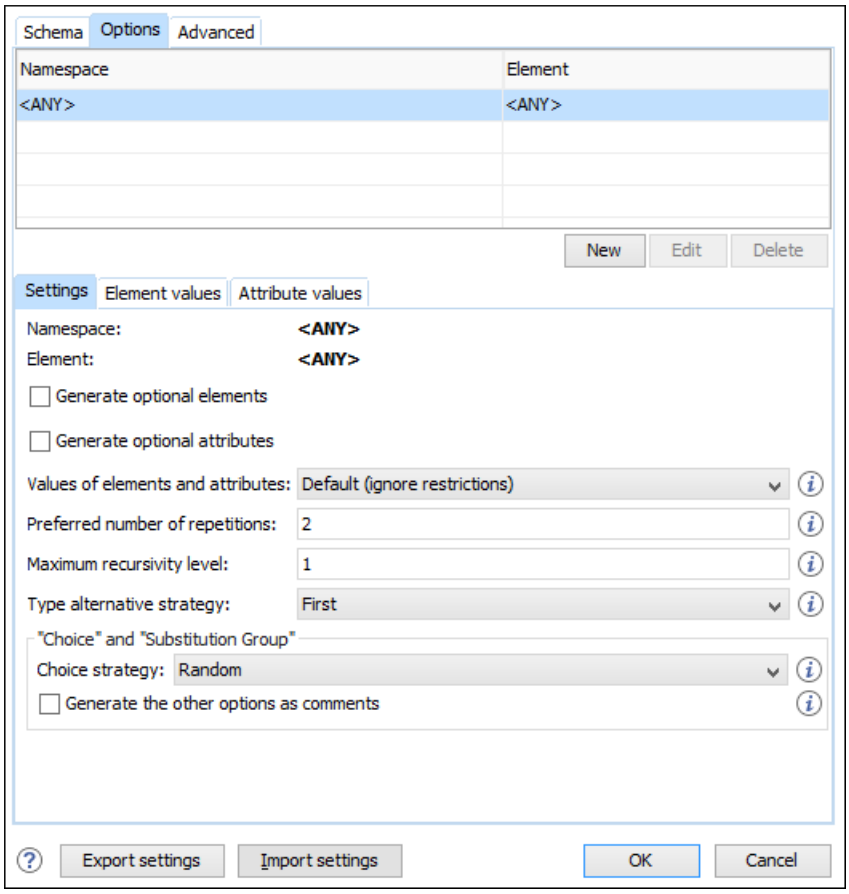

Figure 748: Generate Sample XML Files Dialog Box (Options Tab)

This tab includes the following options:

Namespace / Element table

Allows you to set a namespace for each element name that appears in an XML document instance. The following prefix-to-namespace associations are available:

- All elements from all namespaces (<ANY> - <ANY>). This is the default setting.
- All elements from a specific namespace.
- A specific element from a specific namespace.

Settings subtab

Namespace

Displays the namespace specified in the table at the top of the dialog box.

Element

Displays the element specified in the table at the top of the dialog box.

Generate optional elements

When selected, all elements are generated, including the optional ones (having the `minOccurs` attribute set to 0 in the schema).

Generate optional attributes

When selected, all attributes are generated, including the optional ones (having the `use` attribute set to `optional` in the schema).

Values of elements and attributes

Controls the content of generated attribute and element values. The following choices are available:

- **None** - No content is inserted.
- **Default** - Inserts a default value depending of data type descriptor of the particular element or attribute. The default value can be either the data type name or an incremental name of the attribute or element (according to the global option from the **Sample XML Files Generator** preferences page). Note that type restrictions are ignored when this option is selected. For example, if an element is of a type that restricts an **xs:string** with the **xs:maxLength** facet to allow strings with a maximum length of 3, the XML instance generator tool may generate string element values longer than 3 characters.
- **Random** - Inserts a random value depending of data type descriptor of the particular element or attribute.

  Important: If all of the following are true, the **Generate Sample XML Files** tool outputs invalid values:

  - At least one of the restrictions is a `regexp`.
  - The value generated after applying the regexp does not match the restrictions imposed by one of the facets.

Preferred number of repetitions

Allows you to set the preferred number of repeating elements related to `minOccurs` and `maxOccurs` facets defined in the XML Schema.

- If the value set here is between `minOccurs` and `maxOccurs`, then that value is used.
- If the value set here is less than `minOccurs`, then the `minOccurs` value is used.
- If the value set here is greater than `maxOccurs`, then `maxOccurs` is used.

Maximum recursion level

If a recursion is found, this option controls the maximum allowed depth of the same element.

Type alternative strategy

Used for the `xs:alternative` element from XML Schema 1.1. The possible strategies are:

- **First** - The first valid alternative type is always used.
- **Random** - A random alternative type is used.

Choice strategy

Used for `xs:choice` or `substitutionGroup` elements. The possible strategies are:

- **First** - The first branch of `xs:choice` or the head element of `substitutionGroup` is always used.
- **Random** - A random branch of `xs:choice` or a substitute element or the head element of a `substitutionGroup` is used.

Generate the other options as comments

If selected, generates the other possible choices or substitutions (for `xs:choice` and `substitutionGroup`). These alternatives are generated inside comments groups so you can uncomment and use them later. Use this option with care (for example, on a restricted namespace and element) as it may generate large result files.

Element values subtab

Allows you to add values that are used to generate the content of elements. If there are multiple values, then the values are used in a random order.

Attribute values subtab

Allows you to add values that are used to generate the content of attributes. If there are multiple values, then the values are used in a random order.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

You can click **OK** at any point to generate the sample XML files.

Advanced Tab (Generate Sample XML Files Tool)

The **Generate Sample XML Files** tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The **Advanced** tab allows you to set some options in regards to output values and performance.

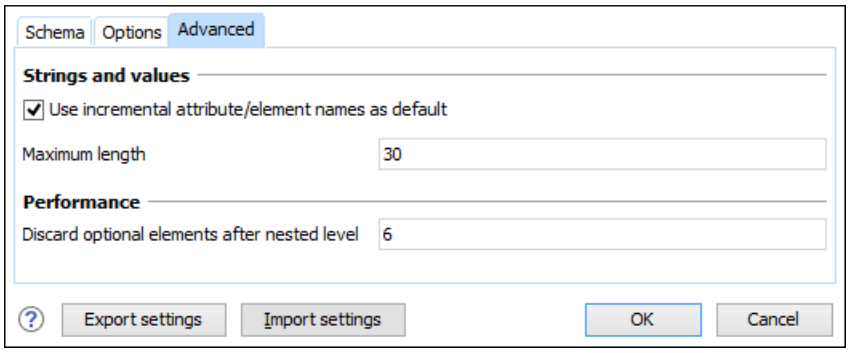

Figure 749: Generate Sample XML Files Dialog Box (Advanced Tab)

This tab includes the following options:

Use incremental attribute / element names as default

If selected, the value of an element or attribute starts with the name of that element or attribute. For example, for an a element the generated values are: a1, a2, a3, and so on. If not selected, the value is the name of the type of that element / attribute (for example: `string`, `decimal`, etc.)

Maximum length

The maximum length of string values generated for elements and attributes.

Discard optional elements after nested level

The optional elements that exceed the specified nested level are discarded. This option is useful for limiting deeply nested element definitions that can quickly result in very large XML documents.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

Running the Generate Sample XML Files Tool from the Command Line

The **Generate Sample XML Files** tool can be also used from command line by running the script called `xmlGenerator.bat` (on Windows) / `xmlGenerator.sh` (on Mac OS X / Unix / Linux) located in the Oxygen XML Editor installation folder. The parameters can be set in the dialog box, exported to an XML file on disk with the **Export settings** button, and then reused from command line. With the exported settings file, you can generate the same XML instances from the command line as from the dialog box. For example:

```
xmlGenerator.bat path_of_CFG_file
```

The script can be integrated in an external batch process launched from the command line. The command line parameter of the script is the relative path to the exported XML settings file. The files specified with relative paths in the exported XML settings will be made absolute relative to the folder where the script is run.

The following example shows such an XML configuration file:

```
<settings>
    <schemaSystemId>http://www.w3.org/2001/XMLSchema.xsd</schemaSystemId>
    <documentRoot>schema</documentRoot>
    <outputFolder>D:\projects\output</outputFolder>
    <filenamePrefix>instance</filenamePrefix>
    <filenameExtension>xml</filenameExtension>
    <noOfInstances>1</noOfInstances>
    <openFirstInstance>true</openFirstInstance>
    <defaultNamespace>&lt;NO_NAMESPACE></defaultNamespace>
    <element namespace="&lt;ANY>" name="&lt;ANY>">
        <generateOptionalElements>false</generateOptionalElements>
        <generateOptionalAttributes>false</generateOptionalAttributes>
        <valuesForContentType>DEFAULT</valuesForContentType>
```

```
        <preferredNumberOfRepetitions>2</preferredNumberOfRepetitions>
        <maximumRecursivityLevel>1</maximumRecursivityLevel>
        <choicesAndSubstitutions strategy="RANDOM"
                generateOthersAsComments="false"/>
        <attribute namespace="&lt;ANY>"
                name="&lt;ANY>">
            <attributeValue>attrValue1</attributeValue>
            <attributeValue>attrValue2</attributeValue>
        </attribute>
    </element>
    <element namespace="&lt;NO_NAMESPACE>"
            name="&lt;ANY>">
        <generateOptionalElements>true</generateOptionalElements>
        <generateOptionalAttributes>true</generateOptionalAttributes>
        <valuesForContentType>DEFAULT</valuesForContentType>
        <preferredNumberOfRepetitions>2</preferredNumberOfRepetitions>
        <maximumRecursivityLevel>1</maximumRecursivityLevel>
        <choicesAndSubstitutions strategy="RANDOM"
                generateOthersAsComments="true"/>
        <elementValue>value1</elementValue>
        <elementValue>value2</elementValue>
        <attribute namespace="&lt;ANY>"
                name="&lt;ANY>">
            <attributeValue>attrValue1</attributeValue>
            <attributeValue>attrValue2</attributeValue>
        </attribute>
    </element>
</settings>
```

Converting Schema to Another Schema Language

The **Generate/Convert Schema** tool allows you to convert a DTD or Relax NG (full or compact syntax) schema or a set of XML files to an equivalent XML Schema, DTD or Relax NG (full or compact syntax) schema. Where perfect equivalence is not possible due to limitations of the target language, Oxygen XML Editor generates an approximation of the source schema. Oxygen XML Editor uses *Trang multiple format converter* to perform the actual schema conversions.

To use this tool, select the **Generate/Convert Schema (Alt + Shift + C (Command + Alt + C on OS X))** action from the **Tools** menu or from the **Open with** submenu when invoking the contextual menu in the ***Project*** *view*. This action opens the **Generate/Convert Schema** dialog box that allows you to configure various options for conversion.

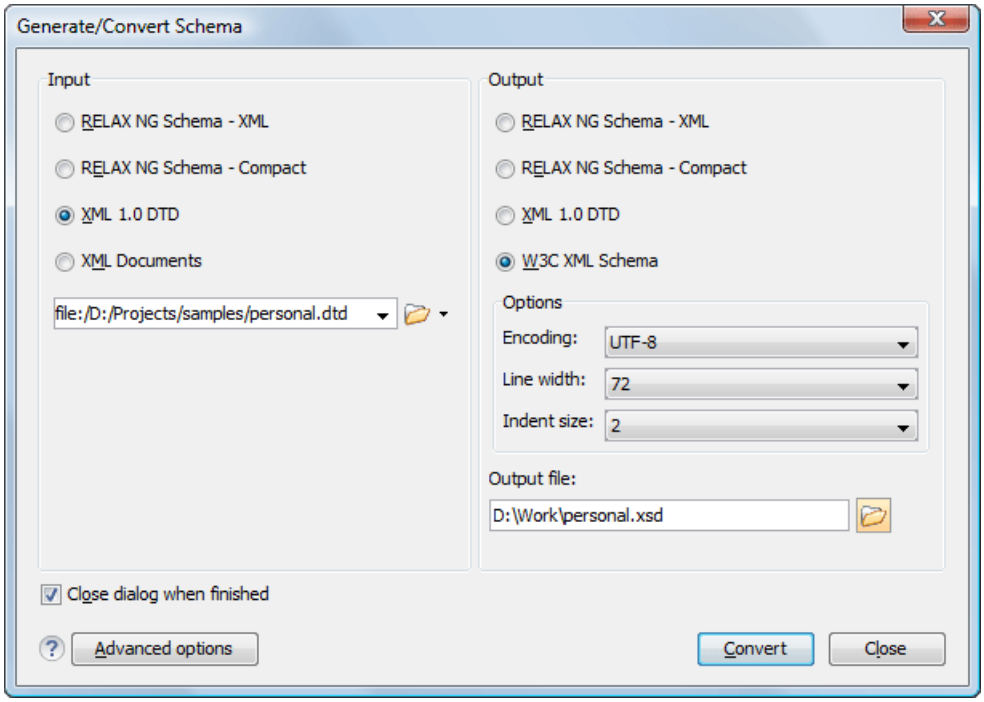

Figure 750: Generate/Convert Schema Dialog Box

The **Generate/Convert Schema** dialog box includes the following options:

Input section

Allows you to select the language of the source schema. If the conversion is based on a set of XML files, rather than just a single XML file, select the **XML Documents** option and use the file selector to add the XML files involved in the conversion.

Output section

Allows you to select the language of the target schema.

Options

You can choose the **Encoding**, the maximum **Line width**, and the **Indent size** (in number of spaces) for one level of indentation.

Output file

Specifies the path for the output file that will be generated.

Close dialog when finished

If you deselect this option, the dialog box will remain opened after the conversion so that you can easily continue to convert more files.

Advanced options

If you select **XML 1.0 DTD** for the input, you can click this button to access more advance options to further fine-tune the conversion. The following advanced options are available:

XML 1.0 DTD Input section

These options apply to the source DTD:

- **xmlns** - Specifies the default namespace, that is the namespace used for unqualified element names.
- **attlist-define** - Specifies how to construct the name of the definition representing an attribute list declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **colon-replacement** - Replaces colons in element names with the specified chars when constructing the names of definitions used to represent the element declarations and attribute list declarations in the DTD.
- **any-name** - Specifies the name of the definition generated for the content of elements declared in the DTD as having a content model of ANY.
- **element-define** - Specifies how to construct the name of the definition representing an element declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **annotation-prefix** - Default values are represented using an annotation attribute `prefix:defaultValue` where prefix is the specified value and is bound to `http://relaxng.org/ns/compatibility/annotations/1.0` as defined by the RELAX NG DTD Compatibility Committee Specification. By default, the conversion engine will use a for prefix unless that conflicts with a prefix used in the DTD.
- **inline-attlist** - Instructs the application not to generate definitions for attribute list declarations, but instead move attributes declared in attribute list declarations into the definitions generated for element declarations. This is the default behavior when the output language is XSD.
- **strict-any** - Preserves the exact semantics of *ANY* content models by using an explicit choice of references to all declared elements. By default, the conversion engine uses a wildcard that allows any element
- **generate-start** - Specifies whether or not the conversion engine should generate a start element. DTD's do not indicate what elements are allowed as document elements. The conversion engine assumes that all elements that are defined but never referenced are allowed as document elements.
- **xmlns mappings** table - Each row specifies the prefix used for a namespace in the input schema.

W3C XML Schema Output section

This section is available if you select **W3C XML Schema** for the output.

- **disable-abstract-elements** - Disables the use of abstract elements and substitution groups in the generated XML Schema. This can also be controlled using an annotation attribute.
- **any-process-contents** - One of the values: strict, lax, skip. Specifies the value for the `processContents` attribute of any elements. The default is skip (corresponding to RELAX NG semantics) unless the input format is DTD, in which case the default is strict (corresponding to DTD semantics).
- **any-attribute-process-contents** - Specifies the value for the `processContents` attribute of `anyAttribute` elements. The default is skip (corresponding to RELAX NG semantics).

Converting Database to XML Schema

Oxygen XML Editor includes a tool that allows you to create an XML Schema from the structure of a database.

To convert a database structure to an XML Schema, use the following procedure:

1. Select the **Convert DB Structure to XML Schema** action from the **Tools** menu.

   Result: The **Convert DB Structure to XML Schema** dialog box is opened and your current database connections are displayed in the **Connections** section.
2. If the database source is not listed, click the **Configure Database Sources** button to open the ***Data Sources*** *preferences page* where you can configure data sources and connections.
3. In the **Format for generated schema** section, select one of the following formats:
   - **Flat schema** - A flat structure that resembles a tree-like view of the database without references to elements.
   - **Hierarchical schema** - Display the table dependencies visually, in a type of tree view where dependent tables are shown as indented child elements in the content model. Select this option if you want to configure the database columns of the tables to be converted.
4. Click **Connect**.

   Result: The database structure is listed in the **Select database tables** section according to the format you chose.
5. Select the database tables that you want to be included in the XML Schema.
6. If you selected **Hierarchical schema** for the format, you can configure the database columns.
   a. Select the database column you want to configure.
   b. In the **Criterion** section you can choose to convert the selected database column as an **Element**, **Attribute**, or to be **Skipped** in the resulting XML Schema.
   c. You can also change the name of the selected database column by changing it in the **Name** text field.
7. Click **Generate XML Schema**.

Result: The database structure is converted to an XML Schema and it is opened for viewing and editing.

Flatten an XML Schema

You can organize an XML schema linked by `xs:include` and `xs:import` statements on several levels. In some cases, working on such a schema as if it were a single file is more convenient than working on multiple files separately. The **Flatten Schema** operation allows you to flatten an entire hierarchy of XML schemas. Starting with the main XML schema, Oxygen XML Editor calculates its hierarchy by processing the `xs:include` and `xs:import` statements.

The **Flatten Schema** action is available from the **Tools** menu or the contextual menu in **Text** mode. The action opens the **Flatten Schema** dialog box that allows you to configure the operation.

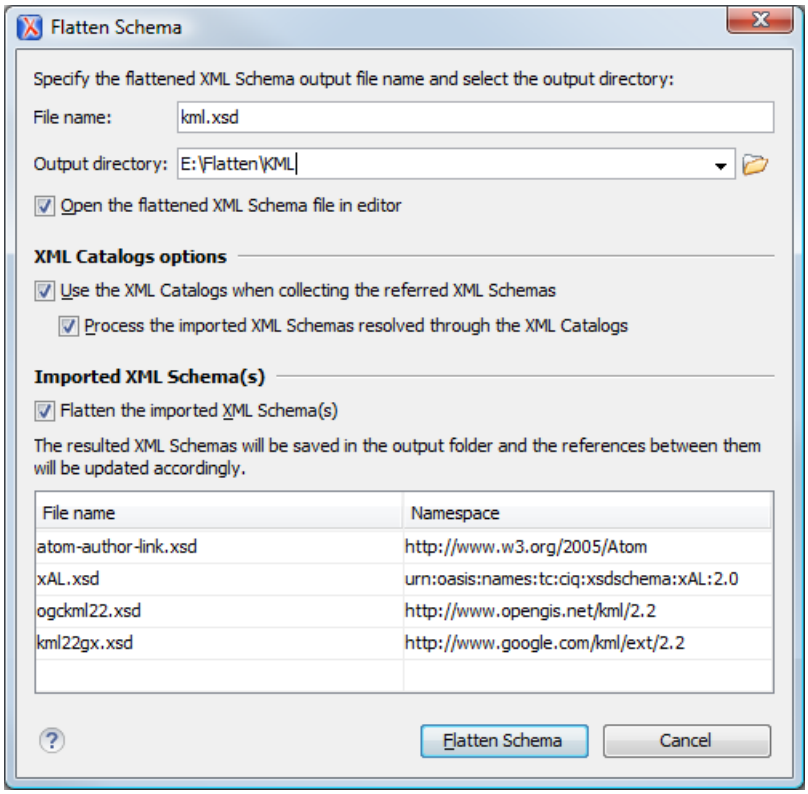

Figure 751: Flatten Schema Dialog Box

For the main schema file and for each imported schema, a new flattened schema is generated in the specified output folder. These schemas have the same name as the original ones.

Note: If necessary, the operation renames the resulted schemas to avoid duplicated file names.

A flattened XML schema is obtained by recursively adding the components of the included schemas into the main one. This means Oxygen XML Editor replaces the `xs:include`, `xs:redefine`, and `xs:override` elements with the ones coming from the included files.

Options in the Flatten Schema Dialog Box

The following options are available in the **Flatten Schema** dialog box:

File name

The name of the output file.

Output directory

The path of the output directory where the flattened schema file will be saved.

Open the flattened XML Schema file in editor

Opens the main flattened schema in the editing area after the operation completes.

Use the XML Catalogs when collecting the referenced XML Schemas

Enables the imported and included schemas to be resolved through the available *XML Catalogs*.

Note: Changing this option triggers the recalculation of the dependencies graph for the main schema.

Process the imported XML Schemas resolved through the XML Catalogs

Specifies whether or not the imported schemas that were resolved through an *XML Catalog* are also processed.

Flatten the imported XML Schema(s)

Specifies whether or not the imported schemas are flattened.

Note: For the schemas skipped by the flatten operation, no files are created in the output folder and the corresponding import statements remain unchanged.

Flatten Schema from the Command Line

The **Flatten Schema** tool can be also ran from command line by using the following command:

- `flattenSchema.bat` on Windows
- `sh flattenSchema.sh` on OS X and Linux

The command line accepts the following parameters:

- `-in:inputSchemaURL` - The input schema URL.
- `-outDir:outputDirectory` - The directory where the flattened schemas should be saved.
- `-flattenImports:<boolean_value>` - Controls whether or not the imported XML Schemas should be flattened. The default value `true`.
- `-useCatalogs:<boolean_value>` - Controls if the references to other XML Schemas should be resolved through the available *XML Catalogs*. The default value `false`.
- `-flattenCatalogResolvedImports:<boolean_value>` - Controls whether or not the imported schemas that were resolved through the *XML Catalogs* should be flattened. The default value is `true`.

  Note: This option is used only when `-useCatalogs` is set to `true`.
- `-verbose` - Provides information about the current flatten XML Schema operation.
- `--help | -help | --h | -h` - Prints the available parameters for the operation.

Example: Command Line Example for Windows

```
flattenSchema.bat -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
   -outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
      -flattenCatalogResolvedImports:true -verbose
```

Example: Command Line Example for OS X

```
sh flattenSchema.sh -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
    -outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
       -flattenCatalogResolvedImports:true -verbose
```

Example: Command Line Example for Unix/Linux

```
sh flattenSchema.sh -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
     -outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
        -flattenCatalogResolvedImports:true -verbose
```

JSON to XML Converter

Oxygen XML Editor includes a useful and simple tool for converting JSON files to XML. It can be found in the **Tools** menu.

To convert a JSON document to XML, follow these steps:

1. Select the **JSON to XML** action from the **Tools** menu.

   The **JSON to XML** dialog box is displayed:

   Figure 752: JSON to XML Dialog Box
2. Choose or enter the **Input URL** of the JSON document.
3. Choose the path of the **Output file** that will contain the resulting XML document.
4. Select the **Open in Editor** option to open the resulting XML document in the main editing pane.
5. Click the **Convert** button.

The original JSON document is now converted to an XML document.

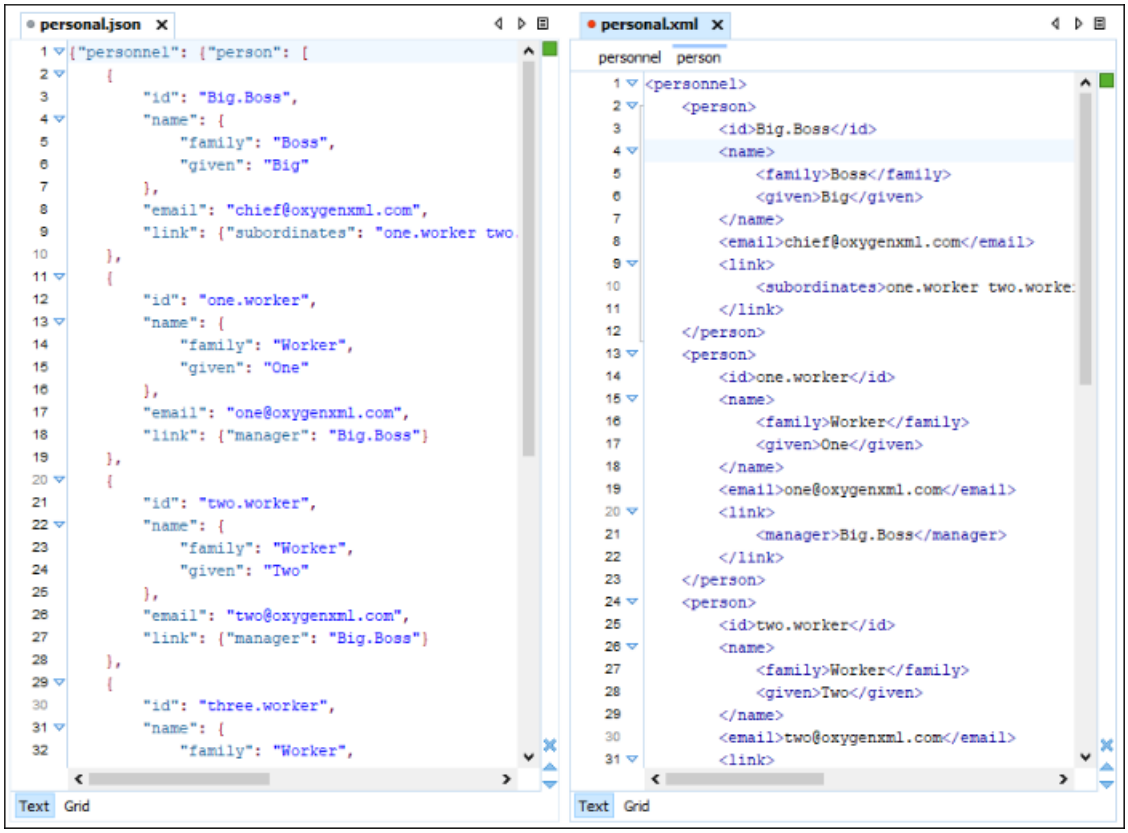

Figure 753: Example: XML to JSON Operation Result

XML to JSON Converter

Oxygen XML Editor includes a useful and simple tool for converting XML files to JSON. It can be found in the **Tools** menu.

To convert an XML document to JSON, follow these steps:

1. Select the **XML to JSON** action from the **Tools** menu.
   The **XML to JSON** dialog box is displayed:

   Figure 754: XML to JSON Dialog Box
2. Choose or enter the **Input URL** of the XML document.
3. Choose the path of the **Output file** that will contain the resulting JSON document.
4. Select the **Open in Editor** option to open the resulting JSON document in the main editing pane.
5. Click the **Convert** button.

The original XML document is now converted to a JSON document.

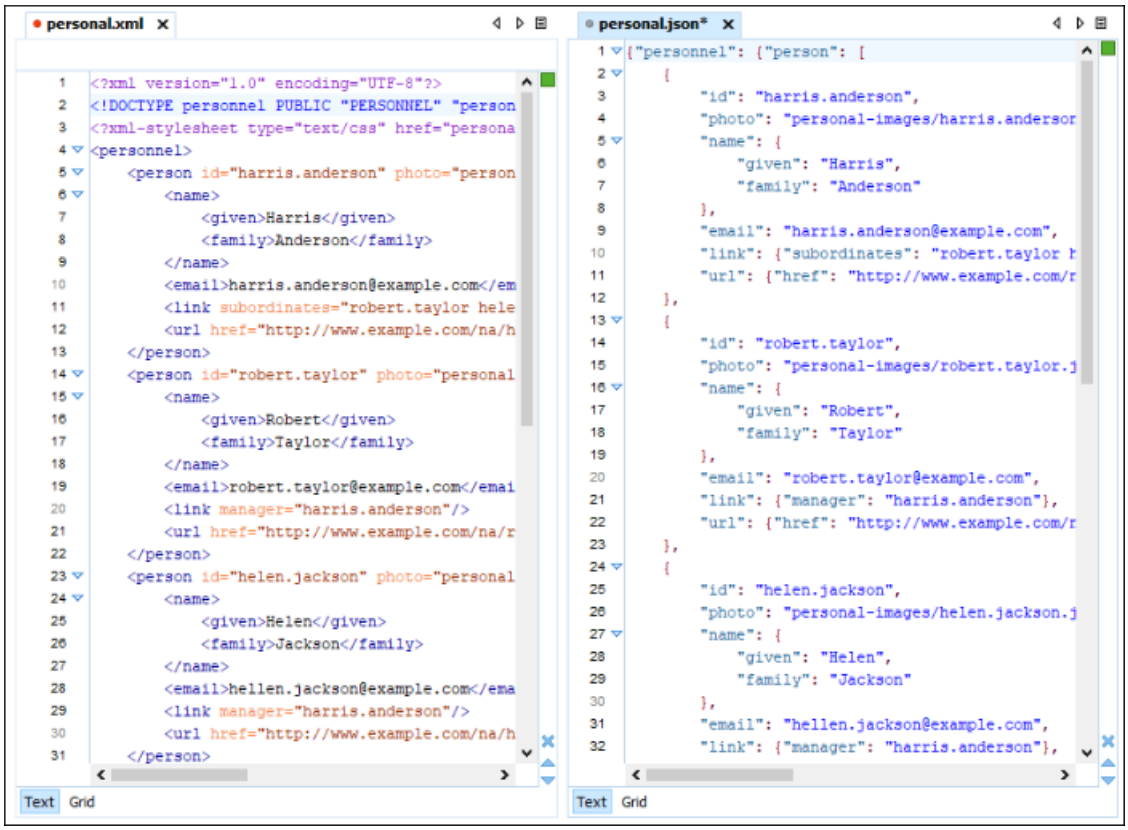

Figure 755: Example: XML to JSON Operation Result

Compiling an XSL Stylesheet for Saxon

As of Saxon 9.7, it is possible to export a compiled form of a stylesheet as an XML file (called a *stylesheet export file* or SEF). Oxygen XML Editor includes a simple tool called **Compile XSL Stylesheet for Saxon** (found in the **Tools** menu) that does this for you.

Use-Cases for a Stylesheet Export File (SEF)

- **Use Saxon-JS to run transformations in a browser** - A *stylesheet export file* (SEF) is needed if you want to use the *Saxon-JS product* to run transformations in a browser, as in the following example:

```
<script type="text/javascript" src="SaxonJS/SaxonJS.min.js"></script>
<script>
    window.onload = function() {
      SaxonJS.transform({
         stylesheetLocation: "books.sef",
         sourceLocation: "books.xml"
         });
    }
</script>
```

- **Use SEF to run transformations in Oxygen XML Editor** - You can also use a *stylesheet export file* (SEF) in Oxygen XML Editor to apply an XSLT transformation over an XML file. This requires **Saxon-EE** or **Saxon-PE** versions of the Saxon product and you must select one of those two versions for the ***Target*** *when you configure the SEF file*. When configuring the XSLT transformation, you will specify the SEF file in the ***XSL URL*** *field*.

Compiling an SEF File

The **Compile XSL Stylesheet for Saxon** tool can be found in the **Tools** menu and it compiles a specified stylesheet as an XML file (*stylesheet export file* with a file extension of `.sef`).

Selecting this tool opens the **Compile XSL Stylesheet for Saxon** dialog box that allows you to configure some options for conversion.

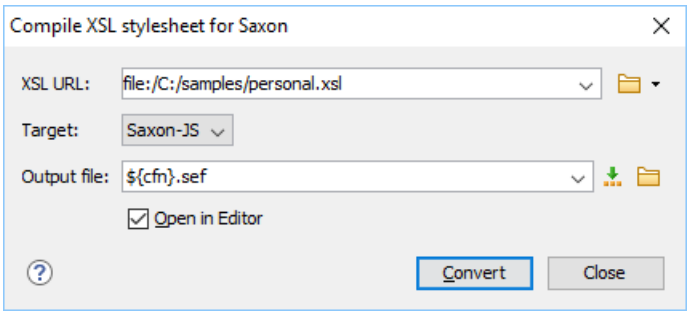

Figure 756: Compile XSL Stylesheet for Saxon Dialog Box

This dialog box includes the following options:

XSL URL

Allows you to select URL of the source XSL stylesheet. You can specify the URL by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down list.

Target

Allows you to select the type of Saxon product that the export file will be used with. You can choose **Saxon-JS**, **Saxon-EE**, **Saxon-PE**, or **Saxon-HE**.

Output file

You can specify the path where the output file will be saved by entering it in the text field, using the **Insert Editor Variables** button, or using the browsing tool button.

Open in Editor

Select this option to open the resulting *stylesheet export file* in the main Oxygen XML Editor editing pane.

Convert

Use this button to generate the *stylesheet export file* according the options selected in this dialog box.

Format and Indent (Pretty-Print) Multiple Files

Oxygen XML Editor provides support for formatting and indenting (*pretty-print*) multiple files at once. This action is available for any document in XML format, as well as for XQuery, CSS, JavaScript, and JSON documents.

To format and indent multiple files, use the **Format and Indent Files** action that is available in the contextual menu of the ***Project*** *view* or from the **Tools** menu. This opens the **Format and Indent Files** dialog box that allows you to configure options for the action.

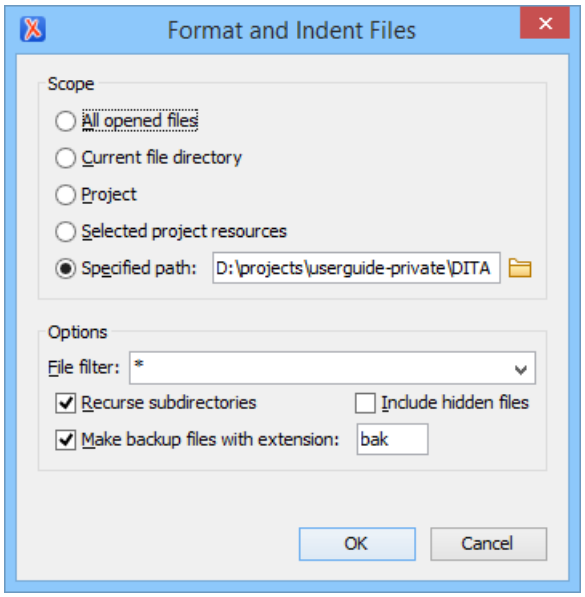

Figure 757: Format and Indent Files Dialog Box

The **Scope** section allows you choose from the following scopes:

- **All opened files** - The *pretty-print* is performed in all opened files.
- **Directory of the current file** - All the files in the folder of the current edited file.
- **Project files** - All files from the current project.
- **Selected project files** - The selected files from the current project.
- **Specified path** - the *pretty-print* is performed in the files located at a specified path.

The **Options** section includes the following options:

- **File filter** - Allow you to filter the files from the selected scope.
- **Recurse subdirectories** - When selected, the *pretty-print* is performed recursively for the specified scope. The one exception is that this option is ignored if the scope is set to **All opened files**.
- **Include hidden files** - When selected, the *pretty-print* is also performed in the hidden files.
- **Make backup files with extension** - When selected, Oxygen XML Editor makes backup files of the modified files. The default extension is `.bak`, but you can change the extension as you prefer.

Generate Documentation

Oxygen XML Editor includes a tool for generating documentation for XSLT, XML Schema, XQuery, and WSDL documents.

Generating Documentation for an XML Schema

Oxygen XML Editor can generate detailed documentation for the components of an XML Schema in HTML, PDF, DocBook, or other custom formats. You can select the components and the level of detail. The components are hyperlinked in both HTML and DocBook documents.

Note: You can generate documentation for both XML Schema version 1.0 and 1.1.

To generate documentation for an XML Schema document, select **XML Schema Documentation** from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project*** *view*.

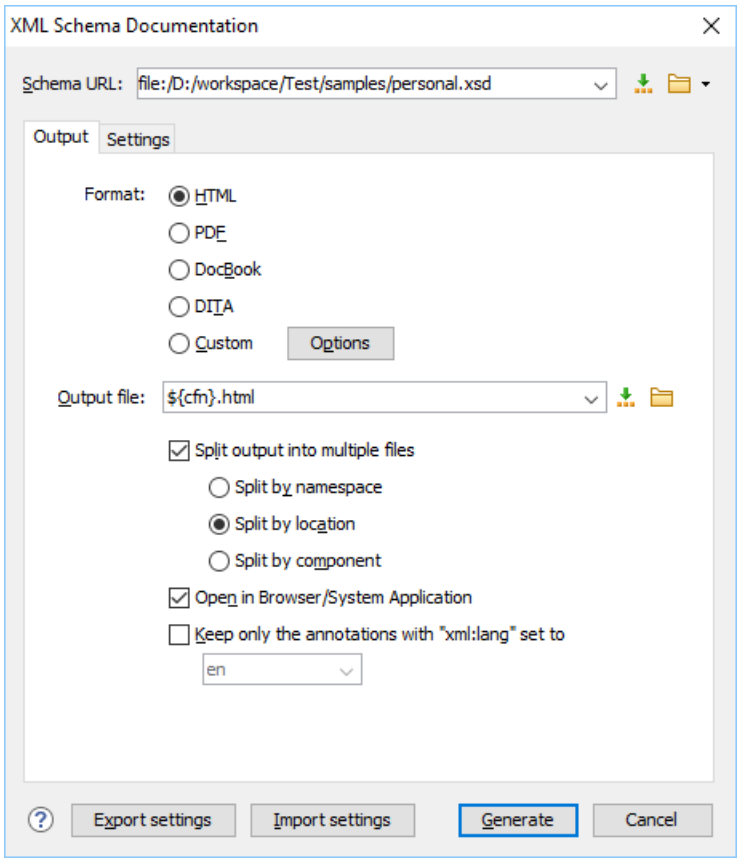

Figure 758: XML Schema Documentation Dialog Box

The **Schema URL** field of the dialog box must contain the full path to the XML Schema (XSD) file for which you want to generate documentation. The schema may be a local or a remote file. You can specify the path to the schema by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in *HTML output format*.
  - **PDF** - The documentation is generated in *PDF output format*.
  - **DocBook** - The documentation is generated in *DocBook output format*.
  - **DITA** - The documentation is generated in *DITA output format*.
  - **Custom** - The documentation is generated in a *custom output format*, allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.
- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type. For DITA and DocBook documents, this option appears as **Open in Editor** and the result will be opened in Oxygen XML Editor (in the current editor).

Note: To set the browser or system application that will be used, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

- **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `xml:lang` attribute set to the selected language. If you choose a primary language code (for example, **en** for English), this includes all its possible variations (**en-us**, **en-uk**, etc.).

Settings Tab

When you generate documentation for an XML schema you can choose what components to include in the output and the details to be included in the documentation.

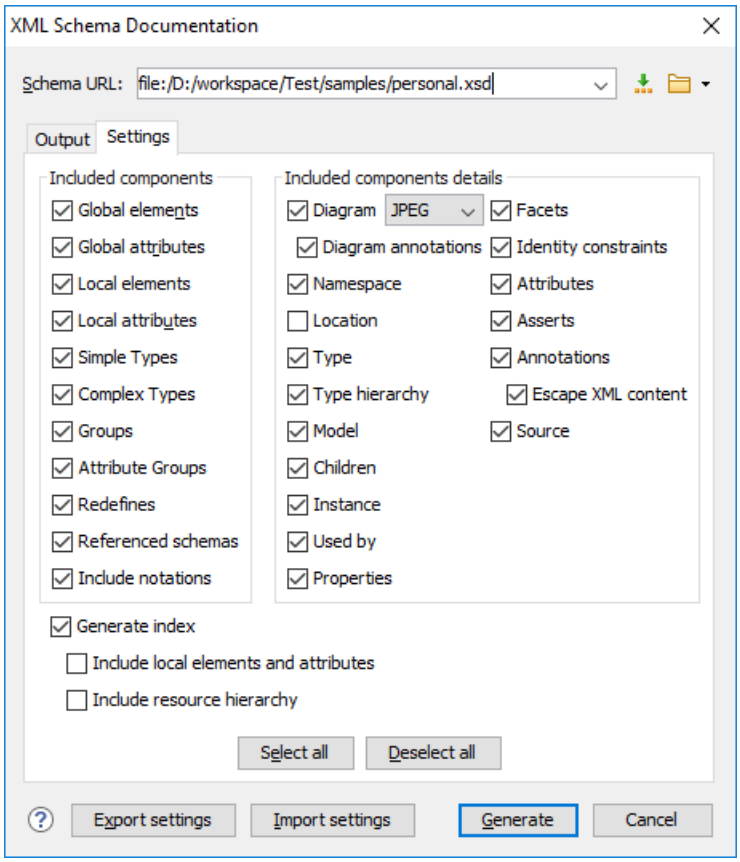

Figure 759: Settings Tab of the XML Schema Documentation Dialog Box

The **Settings** tab allows you to choose whether or not to include the following components: **Global elements**, **Global attributes**, **Local elements**, **Local attributes**, **Simple Types**, **Complex Types**, **Groups**, **Attribute Groups**, **Redefines**, **Referenced schemas**, **Include notations**.

You can choose whether or not to include the following other details:

- **Diagram** - Displays the diagram for each component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section. The generated diagrams are dependent on the options from the *Schema Design Properties* page.
  - **Diagram annotations** - This option controls whether or not the annotations of the components presented in the diagram sections are included.
- **Namespace** - Displays the namespace for each component.
- **Location** - Displays the schema location for each component.
- **Type** - Displays the component type if it is not an anonymous one.
- **Type hierarchy** - Displays the types hierarchy.
- **Model** - Displays the model (sequence, choice, all) presented in BNF form. The separator characters that are used depend upon the information item used:

    - `xs:all` - Its children will be separated by space characters.
    - `xs:sequence` - Its children will be separated by comma characters.
    - `xs:choice` - Its children will be separated by / characters.
- **Children** - Displays the list of component's children.
- **Instance** - Displays an XML instance generated based on each schema element.
- **Used by** - Displays the list of all the components that reference the current one. The list is sorted by component type and name.
- **Properties** - Displays some of the component's properties.
- **Facets** - Displays the facets for each simple type
- **Identity constraints** - Displays the identity constraints for each element. For each constraint there are presented the name, type (unique, key, keyref), reference attribute, selector and field(s).
- **Attributes** - Displays the attributes for the component. For each attribute there are presented the name, type, fixed or default value, usage and annotation.
- **Asserts** - Displays the **assert** elements defined in a complex type. The test, XPath default namespace, and annotation are presented for each assert.
- **Annotations** - Displays the annotations for the component. If you choose **Escape XML Content**, the XML tags are present in the annotations.
- **Source** - Displays the text schema source for each component.
- **Generate index** - Displays an index with the components included in the documentation.
    - **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
    - **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

Export settings - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same *documentation from the command line interface*.)

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the XML Schema documentation.

Generating Documentation for an XSLT Stylesheet

You can use Oxygen XML Editor to generate detailed documentation in HTML format for the elements (top-level elements whose names are in the XSLT namespace) of an XSLT stylesheet. You can select what XSLT elements to include in the generated documentation and also the level of details to present for each of them. The elements are hyperlinked. To generate documentation in a *custom output format*, you can edit the XSLT stylesheet used to generate the documentation, or create your own stylesheet.

To open the **XSLT Stylesheet Documentation** dialog box, select **XSLT Stylesheet Documentation** from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project*** *view*.

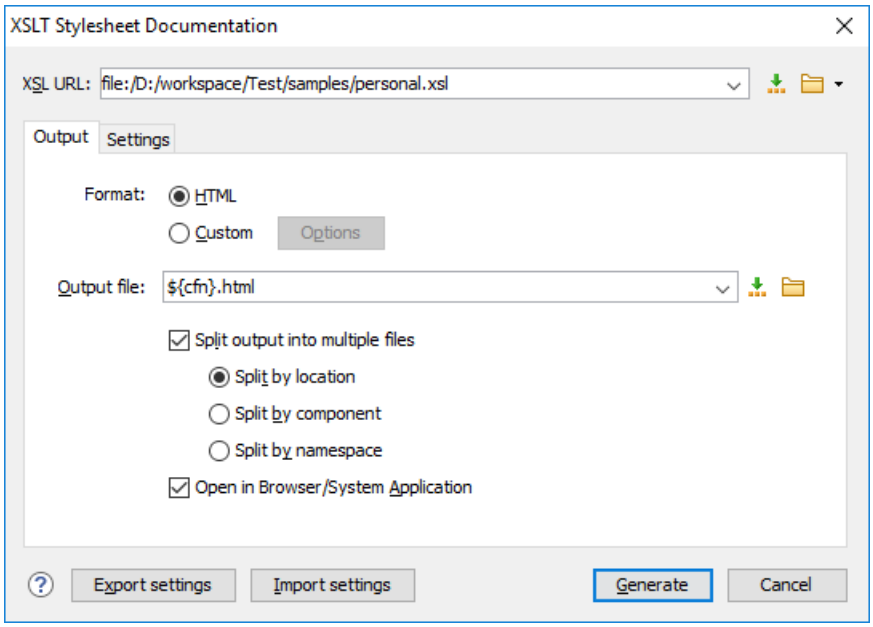

Figure 760: XSLT Stylesheet Documentation Dialog Box

The **XSL URL** field of the dialog box must contain the full path to the XSL Stylesheet file you want to generate documentation for. The stylesheet may be a local or a remote file. You can specify the path to the stylesheet by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in *HTML output format*.
  - **Custom** - The documentation is generated in a *custom output format*, allowing you to control the output. Click the **Options** button to open a ***Custom format options** dialog box* where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.
- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large XSLT stylesheets, choosing another split criterion may generate smaller output files, providing faster documentation browsing. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

  Note: To set the browser or system application that will be used, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

Settings Tab

When you generate documentation for an XSLT stylesheet you can choose what XSLT elements to include in the output (templates, functions, global parameters, global variables, attribute sets, character maps, keys, decimal formats, output formats, XSLT elements from referenced stylesheets) and the details to include in the documentation.

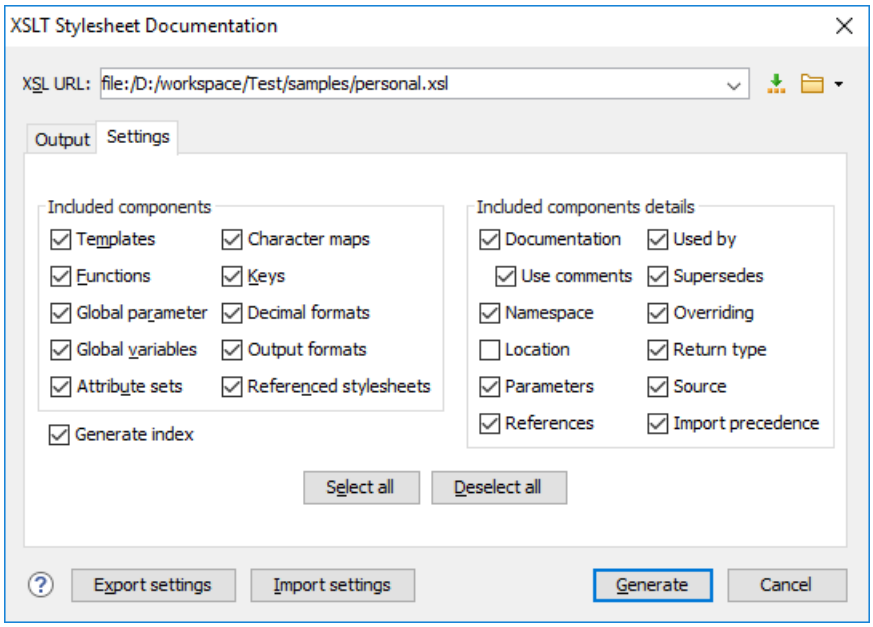

Figure 761: Settings Tab of the XSLT Stylesheet Documentation Dialog Box

The **Settings** tab allows you to choose whether or not to include the following components: **Templates**, **Functions**, **Global parameters**, **Global variables**, **Attribute sets**, **Character maps**, **Keys**, **Decimal formats**, **Output formats**, **Referenced stylesheets**.

You can choose whether or not to include the following other details:

- **Documentation** - Shows the documentation for each XSLT element. For HTML format, the user-defined data elements that are recognized and transformed in documentation blocks of the XSLT elements they precede, are the ones from the following schemas:
  - Oxygen XML Editor built-in XSLT documentation schema.
  - A subset of DocBook 5 elements. The recognized elements are: *section*, *sect1* to *sect5*, *emphasis*, *title*, *ulink*, *programlisting*, *para*, *orderedlist*, *itemizedlist*.
  - A subset of DITA elements. The recognized elements are: *concept*, *topic*, *task*, *codeblock*, *p*, *b*, *i*, *ul*, *ol*, *pre*, *sl*, *sli*, *step*, *steps*, *li*, *title*, *xref*.
  - Full XHTML 1.0 support.
  - XSLStyle documentation environment. XSLStyle uses DocBook or DITA languages inside its own user-defined data elements. The supported DocBook and DITA elements are the ones mentioned above.
  - DOXSL documentation *framework*. Supported elements are : *codefrag*, *description*, *para*, *docContent*, *documentation*, *parameter*, *function*, *docSchema*, *link*, *list*, *listitem*, *module*, *parameter*, *template*, *attribute-set*;

    Other XSLT documentation blocks that are not recognized will just be serialized inside an HTML *pre* element. You can change this behavior by using a *custom format* instead of the built-in *HTML format* and providing your own XSLT stylesheets.
- **Use comments** - Controls whether or not the comments that precede an XSLT element is treated as documentation for the element they precede. Comments that precede or succeed the *xsl:stylesheet* element, are treated as documentation for the whole stylesheet. Note that comments that precede an import or include directive are not collected as documentation for the imported/included module. Also, comments from within the body of the XSLT elements are not collected at all.
- **Namespace** - Shows the namespace for named XSLT elements.
- **Location** - Shows the stylesheet location for each XSLT element.
- **Parameters** - Shows parameters of templates and functions.
- **References** - Shows the named XSLT elements that are referenced from within an element.
- **Used by** - Shows the list of all the XSLT elements that reference the current named element.
- **Supersedes** - Shows the list of all the XSLT elements that are superseded the current element.

- **Overriding** - Shows the list of all the XSLT elements that override the current element.
- **Return type** - Shows the return type of the function.
- **Source** - Shows the text stylesheet source for each XSLT element.
- **Import precedence** - Shows the computed import precedence as declared in the XSL transformation specifications.
- **Generate index** - Creates an index with all the XSLT elements included in the documentation.

Export settings - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same *documentation from the command-line interface*.)

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the XSLT documentation.

Related Information:

XSLT Stylesheet Component Documentation Support on page 742

Generating HTML Documentation for an XQuery Document

To generate HTML documentation for an XQuery document, use the **XQuery Documentation** dialog box. It is opened with the **XQuery Documentation** action that is available from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project*** *view*.

The dialog box allows you to configure a set of parameters for the process of generating the HTML documentation.

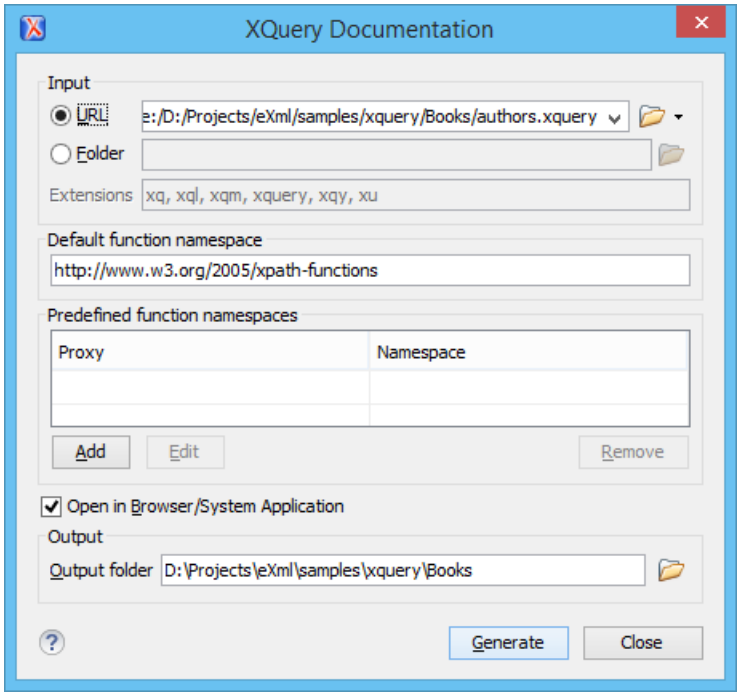

Figure 762: XQuery Documentation Dialog Box

The following options are available:

- **Input** - The full path to the XQuery file must be specified in one of the two fields in this section:
  - **URLFile** - The URL of the file in which you want to generate the documentation.
  - **Folder** - The directory that contains the files for which you want to generate the documentation. You can also specify the XQuery file extensions to be searched for in the specified directory.
- **Default function namespace** - Optional URI for the default namespace for the submitted XQuery.
- **Predefined function namespaces** - Optional, engine-dependent, predefined namespaces that the submitted XQuery refers to. They allow the conversion to generate annotation information to support the presentation

component hypertext linking (only if the predefined modules have been loaded into the local xqDoc XML repository).

- **Open in Browser/System Application** - Select this option if you want the result to be opened in the system application associated with that file type.

  Note: To set the browser or system application that will be used, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.
- **Output** - Allows you to specify where the generated documentation is saved on disk.

Generating Documentation for WSDL Documents

You can use Oxygen XML Editor to generate detailed documentation for the components of a WSDL document in HTML format. You can select the WSDL components to include in your output and the level of details to present for each of them. Also, the components are hyperlinked. You can also generate the documentation in a *custom output format* by using a custom stylesheet.

Note: The WSDL documentation includes the XML Schema components that belong to the internal or imported XML schemas.

To generate documentation for a WSDL document, select **WSDL Documentation** from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project** view*.

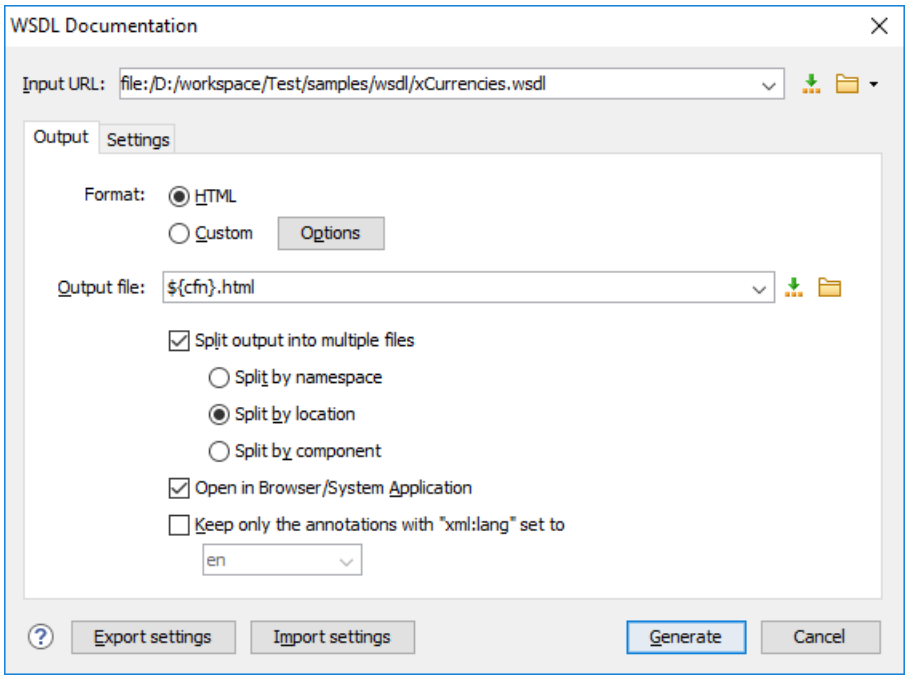

Figure 763: WSDL Documentation Dialog Box

The **Input URL** field of the dialog box must contain the full path to the WSDL document that you want to generate documentation for. The WSDL document may be a local or a remote file. You can specify the path to the WSDL file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in *HTML output format*.
  - **Custom** - The documentation is generated in a *custom output format*, allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom

stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.

- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large WSDL documents, choosing a different split criterion may generate smaller output files providing a faster documentation browsing. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

  Note: To set the browser or system application that will be used, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.
- **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `xml:lang` attribute set to the selected language. If you choose a primary language code (for example, **en** for English), this includes all its possible variations (**en-us**, **en-uk**, etc.).

Setting Tab

When you generate documentation for a WSDL document, you can choose what components to include in the output and the details to be included in the documentation.

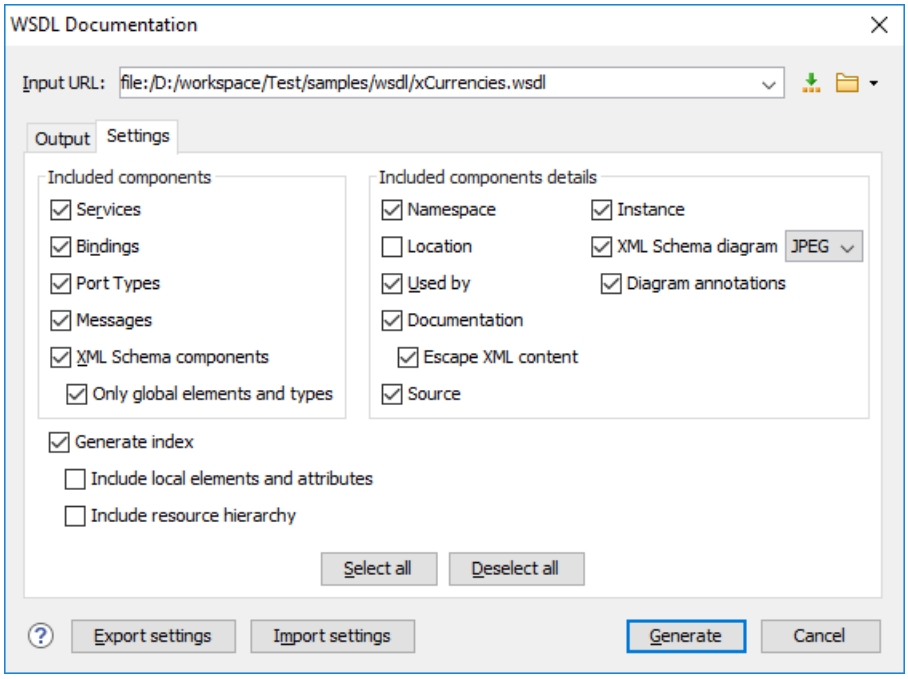

Figure 764: Settings Tab of the WSDL Documentation Dialog Box

The **Settings** tab allows you to choose whether or not to include the following:

- **Components**
  - **Services** - Specifies whether or not the generated documentation includes the WSDL services.
  - **Bindings** - Specifies whether or not the generated documentation includes the WSDL bindings.
  - **Port Types** - Specifies whether or not the generated documentation includes the WSDL port types.
  - **Messages** - Specifies whether or not the generated documentation includes the WSDL messages.
  - **XML Schema Components** - Specifies whether or not the generated documentation includes the XML Schema components.

    - **Only global elements and types** - Specifies whether or not the generated documentation includes only global elements and types.
- **Component Details**
    - **Namespace** - Presents the namespace information for WSDL or XML Schema components.
    - **Location** - Presents the location information for each WSDL or XML Schema component.
    - **Used by** - Presents the list of components that reference the current one.
    - **Documentation** - Presents the component documentation. If you choose **Escape XML Content**, the XML tags are presented in the documentation.
    - **Source** - Presents the XML fragment that defines the current component.
    - **Instance** - Generates a sample XML instance for the current component.

      Note: This option applies to the XML Schema components only.
    - **XML Schema Diagram** - Displays the diagram for each XML Schema component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section.
        - **Diagram annotations** - Specifies whether or not the annotations of the components presented in the diagram sections are included.
- **Generate index** - Displays an index with the components included in the documentation.
    - **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
    - **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

Export settings - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same *documentation from the command-line interface*.)

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the WSDL documentation.

Canonicalizing Files

You can select the *canonicalization* algorithm to be used for a document from the dialog box that is displayed by using the **Canonicalize** action that is available from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

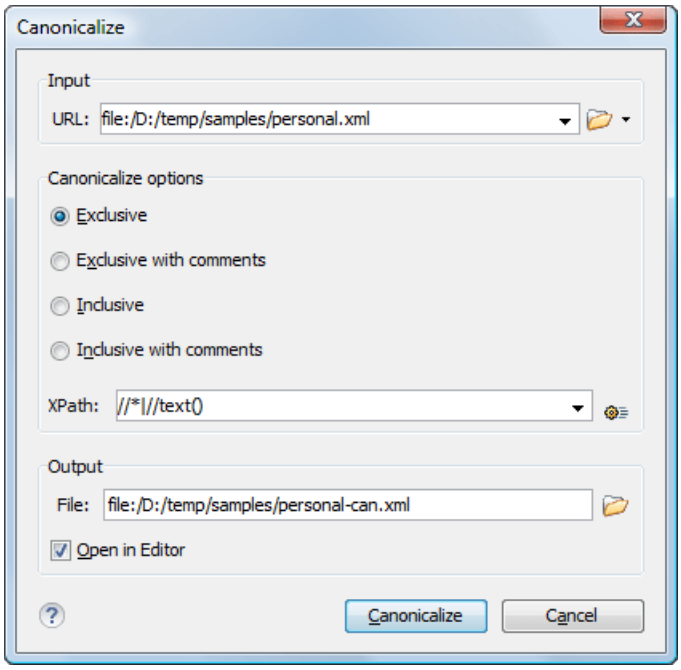

Figure 765: Canonicalization Settings Dialog Box

The **Canonicalize** dialog box allows you to set the following options:

- **Input URL** - Available if the **Canonicalize** action was selected from the **Tools** menu. It allows you to specify the location of the input file.
- **Exclusive** - If selected, the exclusive (uncommented) *canonicalization* method is used.

  Note: *Exclusive Canonicalization* just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.
- **Exclusive with comments** - If selected, the exclusive with comments *canonicalization* method is used.
- **Inclusive** - If selected, the inclusive (uncommented) *canonicalization* method is used.

  Note: *Inclusive Canonicalization* copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive *Canonicalization* is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive *Canonicalization* will copy them and the signature will be invalid.
- **Inclusive with comments** - If selected, the inclusive with comments *canonicalization* method is used.
- **XPath** - The XPath expression provides the fragments of the XML document to be signed.
- **Output** - Available if the **Canonicalize** action was selected from the **Tools** menu. It allows you to specify the output file path where the signed XML document will be saved.
- **Open in editor** - If selected, the output file will be opened in the editor.

Related Information:

Digital Signatures Overview on page 941

Signing Files

You can select the type of signature to be used for documents from a signature settings dialog box. To open this dialog box, select the **Sign** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

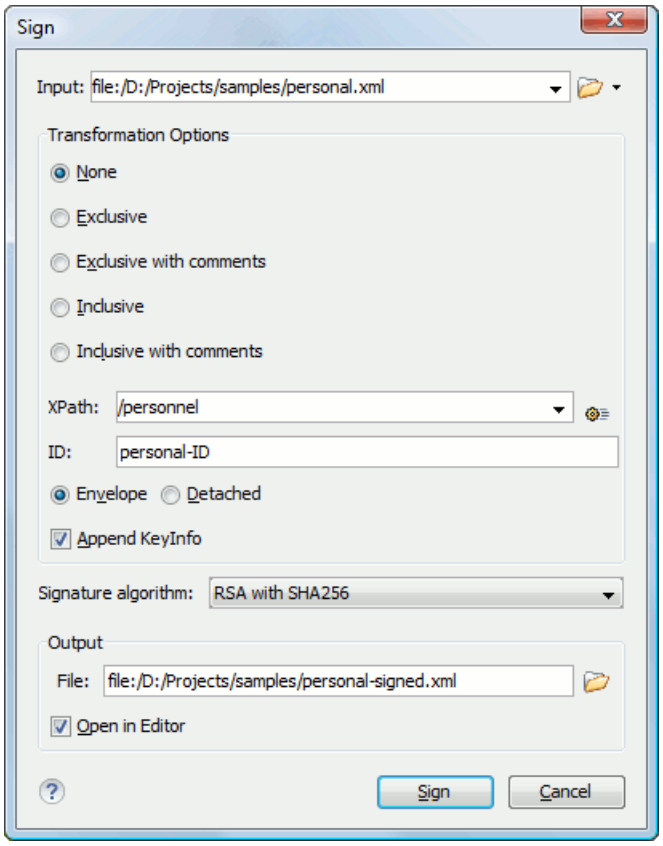

Figure 766: Signature Settings Dialog Box

The following options are available:

Note: If Oxygen XML Editor could not find a valid certificate, a link is provided at the top of the dialog box that opens the *XML Signing Certificates preferences page* where you can configure a valid certificate.

- **Input** - Available if the **Sign** action was selected from the **Tools** menu. Specifies the location of the input URL.
- **Transformation Options** - See the *Digital Signature Overview* section for more information about these options.
  - **None** - If selected, no *canonicalization* algorithm is used.
  - **Exclusive** - If selected, the exclusive (uncommented) *canonicalization* method is used.

    Note: *Exclusive Canonicalization* just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.
  - **Exclusive with comments** - If selected, the exclusive with comments *canonicalization* method is used.
  - **Inclusive** - If selected, the inclusive (uncommented) *canonicalization* method is used.

    Note: *Inclusive Canonicalization* copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive *Canonicalization* is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive *Canonicalization* will copy them and the signature will be invalid.
  - **Inclusive with comments** - If selected, the inclusive with comments *canonicalization* method is used.
- **XPath** - The XPath expression provides the fragments of the XML document to be signed.

- **ID** - Provides ID of the XML element to be signed.
- **Envelope** - If selected, the *enveloped* signature is used. See the *Digital Signature Overview* for more information.
- **Detached** - If selected, the *detached* signature is used. See the *Digital Signature Overview* for more information.
- **Append KeyInfo** - If this option is selected, the `ds:KeyInfo` element will be added in the signed document.
- **Signature algorithm** - The algorithm used for signing the document. The following options are available: **RSA with SHA1**, **RSA with SHA256**, **RSA with SHA384**, and **RSA with SHA512**.
- **Output** - Available if the **Sign** action was selected from the **Tools** menu. Specifies the path of the output file where the signed XML document will be saved.
- **Open in editor** - If selected, the output file will be opened in Oxygen XML Editor.

Verifying Signature

You can verify the signature of a file by selecting the **Verify Signature** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu. The **Verify Signature** dialog box then allows you to specify the location of the file whose signature is verified.

If the signature is valid, a dialog box displays the name of the signer. Otherwise, an error shows details about the problem.

WSDL SOAP Analyzer

WSDL SOAP Analyzer is a tool that helps you test if the messages defined in a Web Service Descriptor (WSDL) are accepted by a Web Services server.

After you edit and validate your Web service descriptor against a mix of the XML Schemas for WSDL and SOAP, it is easy to check if the defined SOAP messages are accepted by the remote Web Services server by using the integrated **WSDL SOAP Analyzer** tool (available from the toolbar or **Tools** menu).

Oxygen XML Editor provides two ways of testing, one for the currently edited WSDL document and another for the remote WSDL documents that are published on a web server. To open the **WSDL SOAP Analyzer** tool for the currently edited WSDL document do one of the following:

- Click the **WSDL SOAP Analyzer** toolbar button.
- Use the **WSDL SOAP Analyzer** action from the **Tools** menu.
- Go to **Open with** > **WSDL SOAP Analyzer** in the contextual menu of the ***Project*** view.

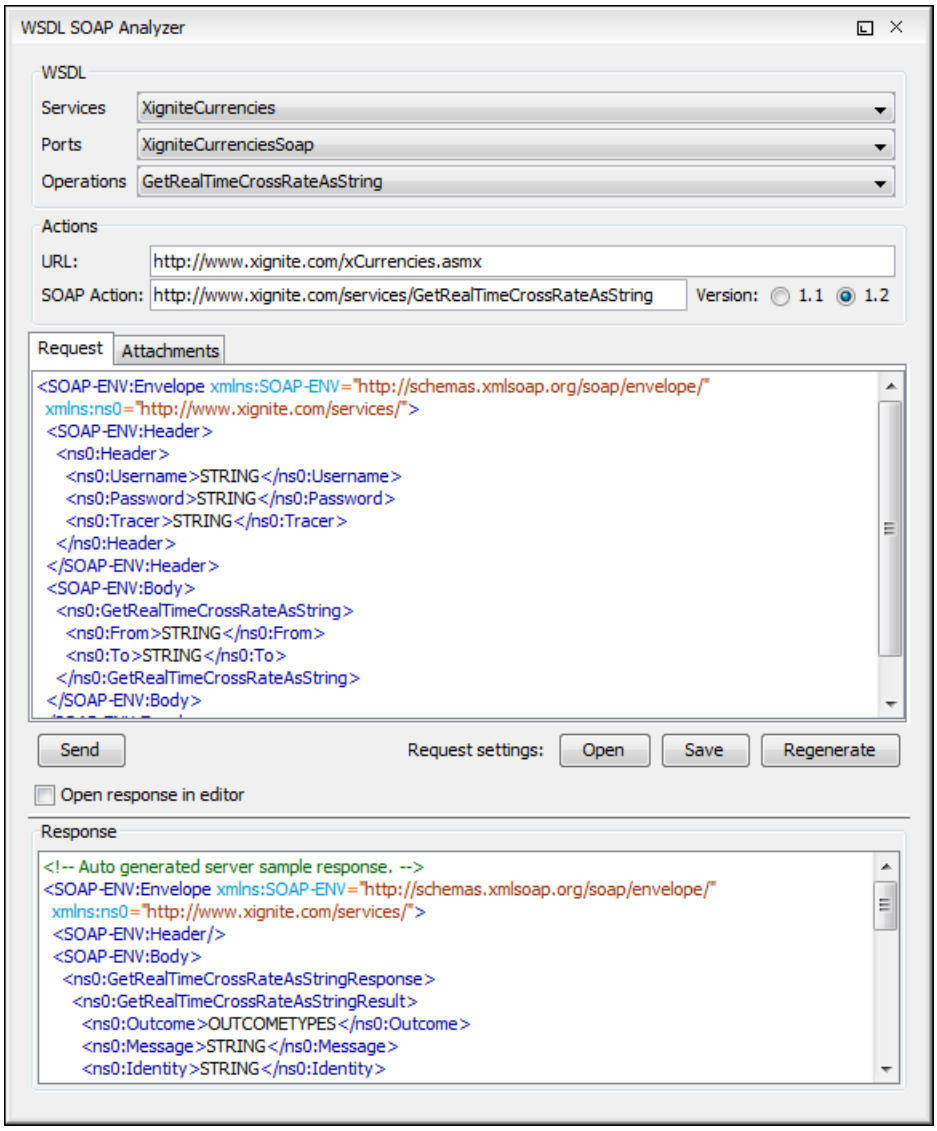

Figure 767: WSDL SOAP Analyzer Dialog Box

This tool contains a SOAP analyzer and sender for Web Services Description Language file types. The analyzer fields are as follows:

- **Services** - The list of services defined by the WSDL file.
- **Ports** - The ports for the selected service.
- **Operations** - The list of available operations for the selected service.
- **Action URL** - The script that serves the operation.
- **SOAP Action** - Identifies the action performed by the script.
- **Version** - Choose between 1.1 and 1.2. The SOAP version is selected automatically depending on the selected port.
- **Request Editor** - It allows you to compose the web service request. When an action is selected, Oxygen XML Editor tries to generate as much content as possible for the SOAP request. The envelope of the SOAP request has the correct namespace for the selected SOAP version, that is *http://schemas.xmlsoap.org/soap/envelope/* for SOAP 1.1 or *http://www.w3.org/2003/05/soap-envelope* for SOAP 1.2. Usually you just have to change a few values for the request to be valid. The *Content Completion Assistant* is available for this editor and is driven by the schema that defines the type of the current message. While selecting various operations, Oxygen XML Editor remembers the modified request for each one. You can press the **Regenerate** button to overwrite your modifications for the current request with the initial generated content.
- **Attachments List** - You can define a list of file URLs to be attached to the request.

- **Response Area** - Initially it displays an auto generated server sample response so you can have an idea about how the response looks like. After pressing the **Send** button, it presents the message received from the server in response to the Web Service request. It may show also error messages. If the response message contains attachments, Oxygen XML Editor prompts you to save them, then tries to open them with the associated system application.
- **Errors List** - There may be situations where the WSDL file is respecting the WSDL XML Schema, but it fails to be valid (for example, in the case of a message that is defined by means of an element that is not found in the types section of the WSDL). In such a case, the errors are listed here. This list is presented only when there are errors.
- **Send Button** - Executes the request. A status dialog box is displayed when Oxygen XML Editor is connecting to the server.

The testing of a WSDL file is straight-forward: click the WSDL analysis button, then select the service, the port, and the operation. The editor generates the skeleton for the SOAP request. You can edit the request, eventually attach files to it and send it to the server. Watch the server response in the response area. You can find more details in the *Testing Remote WSDL Files* section.

Note: SOAP requests and responses are automatically validated in the **WSDL SOAP Analyzer** using the XML Schemas specified in the WSDL file.

Once defined, a request derived from a Web Service descriptor can be saved with the **Save** button to a Web Service SOAP Call (WSSC) file for later reuse. In this way, you save time in configuring the URLs and parameters.

You can open the result of a Web Service call in an editor panel using the **Open** button.

Testing Remote WSDL Files

To open and test a remote WSDL file the steps are the following:

1. Go to **Tools** > **WSDL SOAP Analyzer** .
2. On the **WSDL File** tab enter the URL of the remote WSDL file.
   You enter the URL:
   - by typing
   - by browsing the local file system
   - by browsing a remote file system
   - by browsing *a UDDI Registry*
3. Press the **OK** button.
   This will open the ***WSDL SOAP Analyzer** tool*. In the **Saved SOAP Request** tab you can open directly a previously saved Web Service SOAP Call (WSSC) file, thus skipping the analysis phase.

UDDI Registry Browser

Pressing the button in the **WSDL File Opener** dialog box (menu **Tools** > **WSDL SOAP Analyzer**) opens the **UDDI Registry Browser** dialog box.

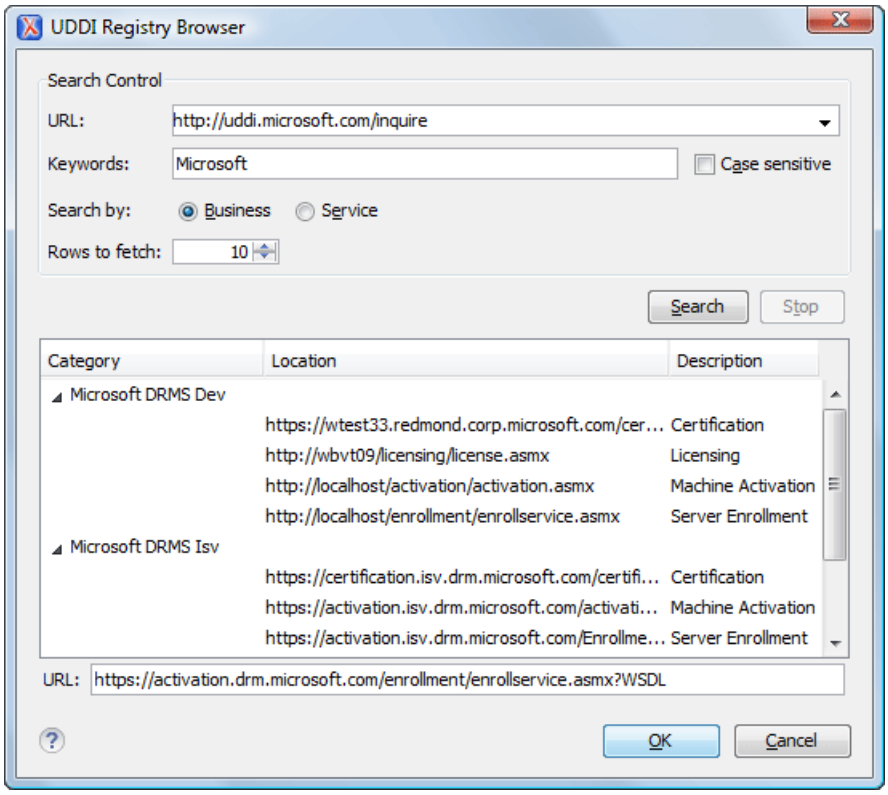

Figure 768: UDDI Registry Browser Dialog Box

The fields of the dialog box are as follows:

- **URL** - Type the URL of an UDDI registry or choose one from the default list.
- **Keywords** - Enter the string you want to be used when searching the selected UDDI registry for available Web services.
- **Rows to fetch** - The maximum number of rows to be displayed in the result list.
- **Search by** - You can choose to search either by company or by provided service.
- **Case sensitive** - When selected, the search takes into account the keyword case.
- **Search** - The WSDL files that matched the search criteria are added in the result list.

When you select a WSDL from the list and click the **OK** button, the **UDDI Registry Browser** dialog box is closed and you are returned to the **WSDL File Opener** dialog box.

XML Schema Regular Expressions Builder

The XML Schema regular expressions builder allows you to test regular expressions on a fragment of text as they are applied to an XML instance document. Start the tool by selecting **XML Schema Regular Expressions Builder** from the **Tools** menu.

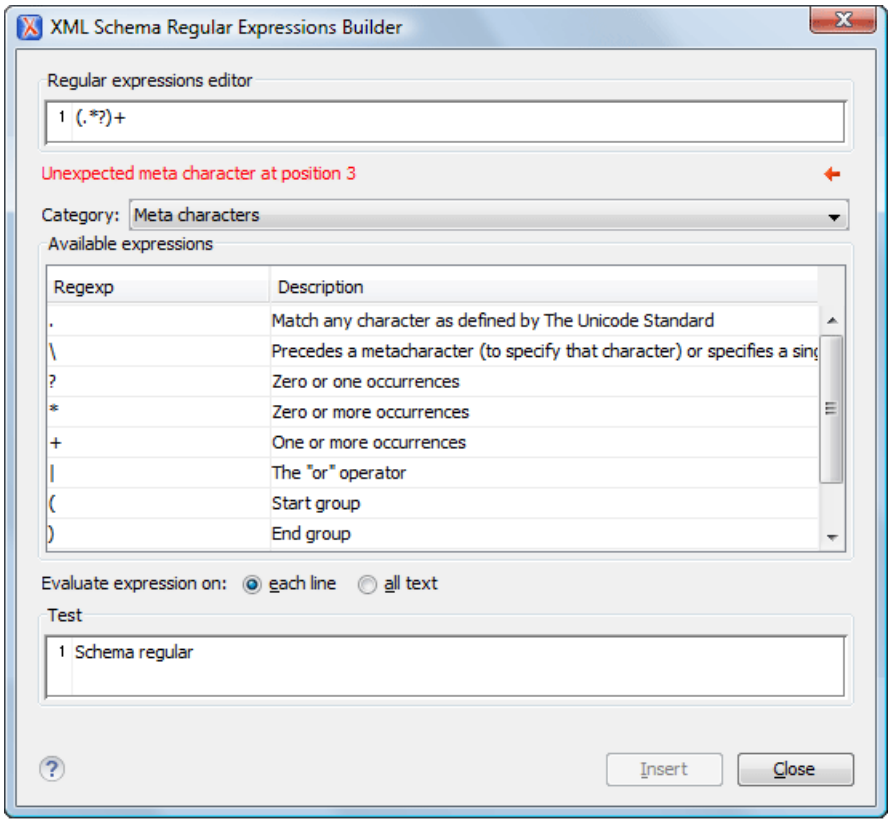

Figure 769: XML Schema Regular Expressions Builder Dialog Box

The dialog box contains the following:

Regular expressions editor

Allows you to edit the regular expression to be tested and used. Content completion is available and presents a list with all the predefined expressions. It is triggered by pressing **Ctrl + Space (Command + Space on OS X)**.

Error display area

If the edited regular expression is incorrect, an error message will be displayed here. The message contains the description and the exact location of the error. Also, clicking the quick navigation button (←) highlights the error inside the regular expression.

Category

You can choose from several categories of predefined expressions. The selected category influences the displayed expressions in the **Available expressions** table.

Available expressions

This table includes the available regular expressions and a short description for each of them. The set of expressions depends on the category selected in the previous **Category** combo box. You can add an expression in the **Regular expressions editor** by double-clicking the expression row in the table. You will notice that in the case of **Character categories** and **Block names**, the expressions are also listed in complementary format.

Evaluate expression on

You can choose between two options:

- **Evaluate expression on each line** - The edited expression will be applied on each line in the **Test** area.
- **Evaluate expression on all text** - The edited expression will be applied on the whole text.

Test

A text editor that allows you to enter a text sample for which the regular expression will be applied. All matches of the edited regular expression will be highlighted.

After editing and testing your regular expression you can insert it in the current editor. The **Insert** button will become active when an editor is opened in the background and there is an expression in the **Regular expressions editor**.

The regular expression builder cannot be used to insert regular expressions in the ***Grid*** *mode* or *schema* ***Design*** *mode*. Accordingly, the **Insert** button will be not available if the current document is edited in these modes.

Note: Some regular expressions may indefinitely block the Java Regular Expressions engine. If the execution of the regular expression does not end in about five seconds, the application displays a dialog box that allows you to interrupt the operation.

Large File Viewer

XML files tend to become larger and larger mostly because they are frequently used as a format for database export or for porting between multiple database formats. Traditional XML text editors simply cannot handle opening these huge export files, some having sizes exceeding one gigabyte, because all the file content must be loaded in memory before the user can actually view it.

The best performance of the viewer is obtained for encodings that use a fixed number of bytes per character (such as UTF-16 or ASCII). The performance for UTF-8 is very good for documents that use mostly characters of the European languages. For the same encoding, the rendering performance is higher for files consisting of long lines (up to few thousands characters) and may degrade for short lines. In fact, the maximum size of a file that can be rendered in the Large File Viewer decreases when the total number of the text lines of the file increases. Trying to open a very large file (for example, a file of 4 GB) with a very high number of short lines (100 or 200 characters per line) may produce an *out of memory* error (**OutOfMemoryError**) that would require either increasing the Java heap memory with the -Xmx startup parameter or decreasing the total number of lines in the file.

The powerful **Large File Viewer** is available from the **Tools** menu or as a standalone application. You can also right-click a file in your project and choose to open it with the viewer. It uses an efficient structure for indexing the opened document. No information from the file is stored in the main memory, just a list of indexes in the file. In this way the viewer can open very large files, up to 10 gigabytes. If the opened file is XML, the encoding used to display the text is detected from the XML prolog of the file. For other file types, the encoding is taken from the Oxygen XML Editor options. See *Encoding for non XML files*.

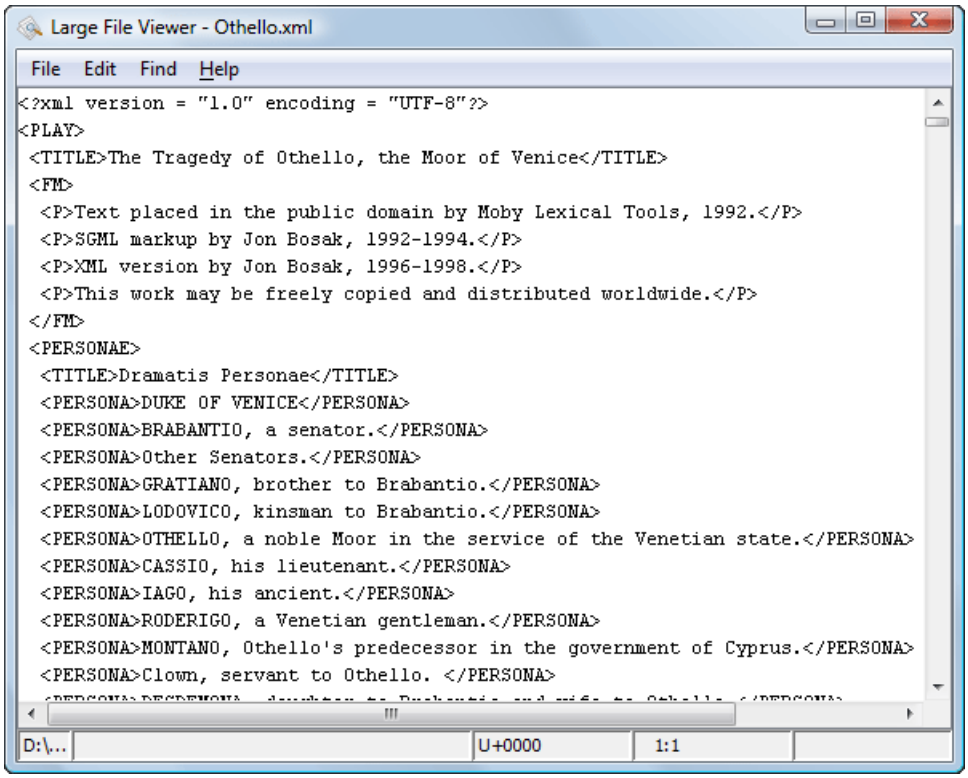

Figure 770: Large File Viewer

Large File Viewer components:

- The menu bar provides menu driven access to all the features and functions that are available in **Large File Viewer**:

  File > Open

  Opens files in the viewer (also available in the contextual menu).

  File > Exit

  Closes the viewer.

  Edit > Copy

  Copies the selected text to clipboard (also available in the contextual menu).

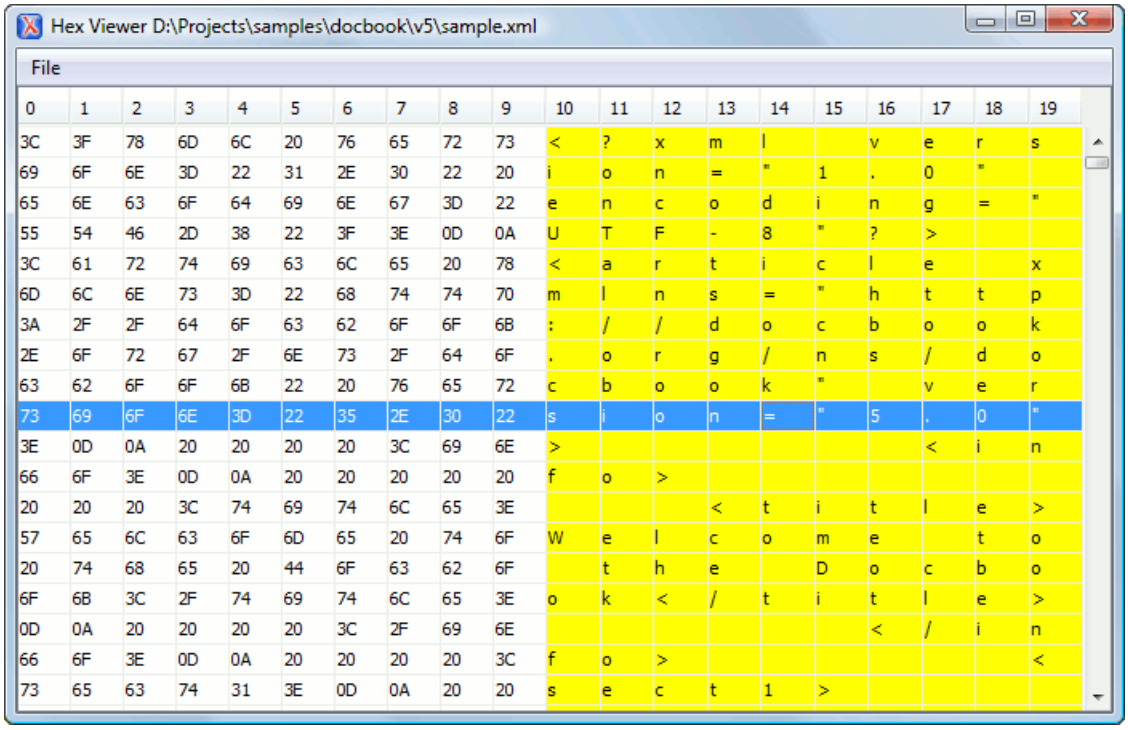
  Find > Find

  Opens a reduced **Find** dialog box that provides some basic search options, such as:

  - **Case sensitive** - When selected, operations are case-sensitive.
  - **Regular Expression** - When selected, allows you to use any regular expression in *Perl-like syntax*.
  - **Wrap around** - Continues the find operation from the start/end of the document after reaching the end/, depending on whether the search is in forward or backward direction.

  Help > Help

  Provides access to the User Manual.



- The status bar provides information about the current opened file path, the Unicode representation of the character at cursor position and the line and column in the opened document where the cursor is located.

Attention: For faster computation the **Large File Viewer** uses a fixed font (plain, monospace font of size 12) to display characters. The font is *not* configurable from the ***Preferences** page*.

Tip: The best performance of the viewer is accomplished for encodings that use a fixed number of bytes per character (such as UTF-16 or ASCII). The performance for UTF-8 is very good for documents that use mostly characters of the European languages. For the same encoding the rendering performance is high for files consisting of short lines (up to a few thousand characters) and may degrade for long lines.

Hex Viewer

When the Unicode characters that are visible in a text viewer or editor are not enough and you need to see the byte values of each character of a document, you can start the **Hex Viewer** that is available on the **Tools** menu. It has two panels: the characters are rendered in the right panel and the bytes of each character are displayed in the left panel. There is a 1:1 correspondence between the characters and their byte representation: the byte representation of a character is displayed in the same matrix position of the left panel as the character in the matrix of the right panel.

Figure 771: Hex Viewer

To open a file in **Hex Viewer** use the **File** > **Open** action. Alternatively, you can drag a file and drop it in the **Hex Viewer** panel.

Standalone SVG Viewer

Oxygen XML Editor includes a simple **SVG Viewer** that allows you to work with SVG images.

To open the viewer, select **SVG Viewer** from the **Tools** menu.

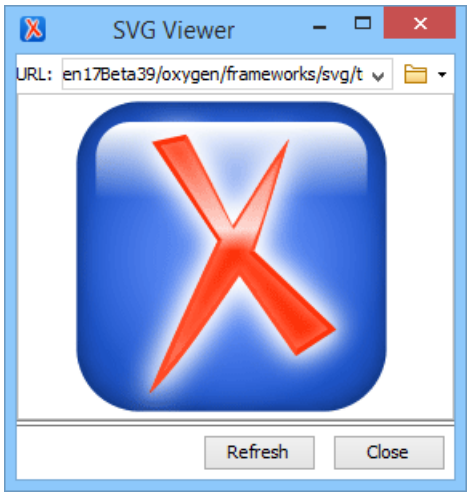

Figure 772: SVG Viewer

You can browse for and open any SVG file that has the `.svg` or `.svgz` extension.

If the file is included in the current project, you can open it in the viewer by right-clicking the image file in the ***Project*** *view* and selecting **Open with** > **SVG Viewer**.

Actions Available in the SVG Viewer

The following actions are available in the **SVG Viewer**:

Zoom in

To zoom in on an image, use any of the following methods:

- Scroll **forward** with the mouse wheel.
- Select **Zoom in** from the contextual menu.
- Use the **Ctrl + I (Command + I on OS X)** keyboard shortcut.

Zoom out

To zoom in on an image, use any of the following methods:

- Scroll **backward** with the mouse wheel.
- Use the **Ctrl + O (Command + O on OS X)** keyboard shortcut.
- Select **Zoom out** from the contextual menu.

Rotate

To rotate an image, use either of the following methods:

- Use the **Ctrl + Right-Click + Drag (Command + Right-Click + Drag on OS X)** shortcut.
- Select **Rotate** from the contextual menu. This rotates the image exactly 90 degrees clockwise.

Refresh

To refresh (or reset) an image, use either of the following methods:

- Use the **Ctrl + T (Command + T on OS X)** keyboard shortcut.
- Select **Refresh** from the contextual menu.

Move

To move an image, use either of the following methods:

- Use the **Arrow Keys** on your keyboard.
- Use the **Shift + Left-Click + Drag** shortcut.

Pan

To pan an image, **click and drag** the image with your mouse.

Related Information:
Editing SVG Files on page 918

Tree Editor

The **Tree Editor** (**Tools** > **Tree Editor**) is used for editing the content of a document displayed as an XML tree. The workspace offers the following functional areas:

- Main menu - Provides access to all the features and functions available in Oxygen XML Editor **Tree Editor**.
- Toolbar - Provides easy access to common and frequently used functions. Each icon is a button that acts as a shortcut to a related function.
- Editor panel - Easy editing of structured mark-up documents. Each token has an associated icon for easier visual identification.
- Message panel - Displays messages returned from user operations.
- Model view - Shows the detailed information about the attribute or element that you are working on.
- All Elements panel - Presents a list of all defined elements that can be inserted within your document.

The tree editor does not offer entity support. Entities are not presented with a special type of node in the tree and new entity nodes cannot be inserted in the document.

Compare Files

The **Compare Files** tool can be used to compare files or XML file fragments. The tool provides a mechanism for comparing two files or fragments, as well as the mechanism for a three-way comparison. The utility is available from the **Tools** menu or can be opened as a stand-alone application from the Oxygen XML Editor installation folder (`diffFiles.exe`).

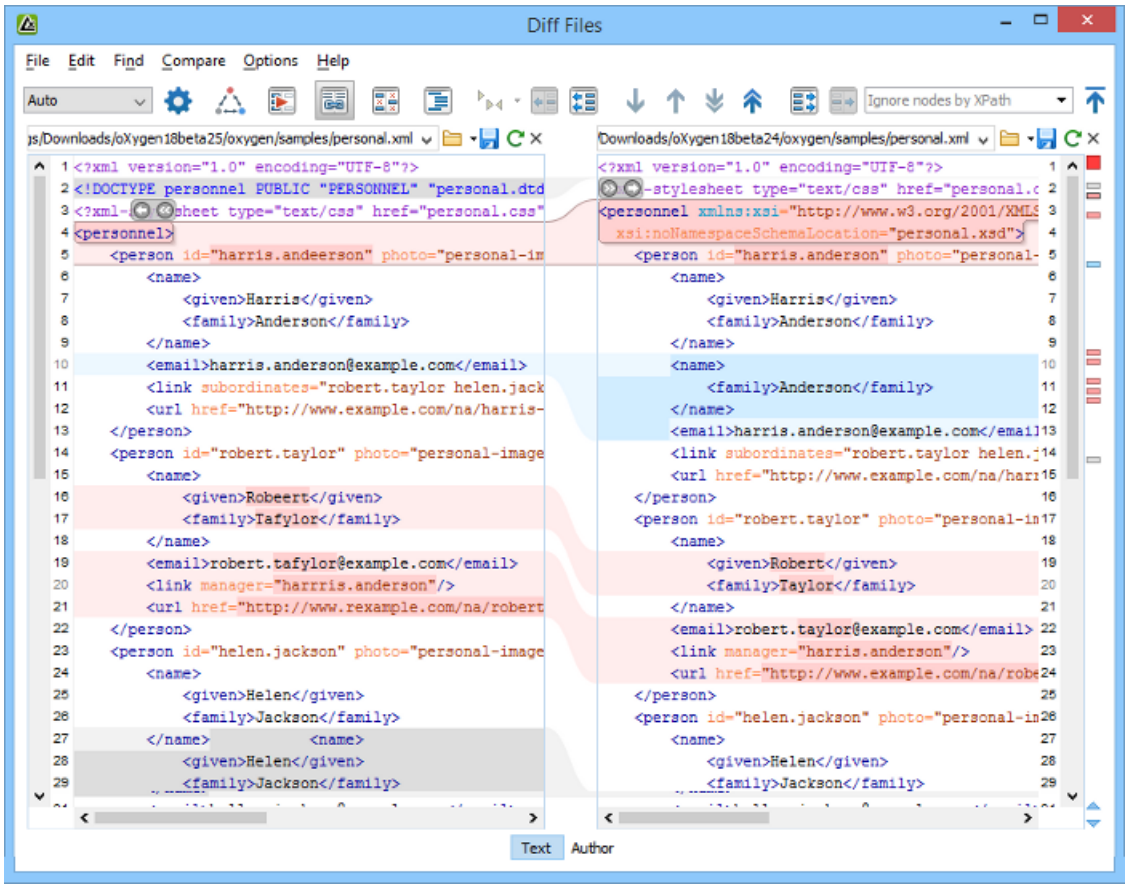

Figure 773: Compare Files Tool

Two-Way Comparisons

The **Compare Files** tool can be used to compare the differences between two files or XML fragments.

Compare Files

To perform a two-way comparison, follow these steps:

1. Open a file in the left panel and the file you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down menu.

   Step Result: The selected files are opened in the two side-by-side editors. A text editing mode is used to offer a better view of the differences.
2. To highlight the differences between the two files, click the **Perform File Differencing** button from the toolbar.
3. You can use the drop-down menu on the left side of the toolbar to change the *algorithm* for the operation.
4. You can also use the **Diff Options** button to access the **Files Comparison** preferences page where you can choose to ignore certain types of markup and configure various options.
5. If you are comparing XML documents using the **XML Fast** or **XML Accurate** algorithms, you can enter an XPath 2.0 expression in the **Ignore nodes by XPath** text field to ignore certain nodes from the comparison.

The resulting comparison will show you differences between the two files. The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes. This layout allows you to easily identify and focus on a group of related changes.

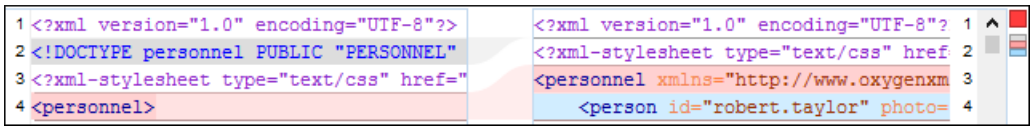

Figure 774: Two-Way Differences

Highlighting Colors

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the ***Files Comparison / Appearance*** *preferences page*, but the default colors and their shades mean the following:

- **Pink** - Identifies modifications on either side.
- **Gray** - Identifies an addition of a node in the left side (your outgoing changes).
- **Blue** - Identifies an addition of a node in the right side (incoming changes).
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Comparing Fragments (Copy/Paste)

To compare XML file fragments, you need to copy and paste the fragments you want to compare into each side, without selecting a file. If a file is already selected, you need to close it using the **Close (Ctrl + W (Command + W on OS X))** button, before pasting the fragments. Other notes for pasting fragments:

- As long as the fragment is more than 10 characters, the application will attempt to automatically detect the content type. It can detect the following types: XML, DTD, CSS, JSON, and Markdown (if it starts with #). If one of those content types is detected, the fragments will be displayed with syntax highlights.
- If you save modified fragments, a dialog box opens that allows you to save the changes as a new document.

Navigate Differences

To navigate through differences, do one of the following:

- Use the navigation buttons on the toolbar (or in the **Compare** menu).

- Select a block of differences by clicking its small colored marker in the overview ruler located in the right-most part of the window. At the top of the overview ruler there is a success indicator that turns green where there are no differences, or red if differences are found.
- Click a colored area in between the two text editors.

Editing Actions

You can edit the files directly in either editing pane. The two editors are constantly synchronized and the differences are refreshed when you save the modified document or when you click the  **Perform File Differencing** button.

A variety of actions are available on the *toolbar* and in the *various menus* (these same actions are also available in the contextual menu in both editing panes). The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

 **Append left change to right and**  **Append right change to left**

Copies the content of the selected change from one side and appends it on the other, according to the content of the corresponding change. As a result, the side where the arrow points to will contain the changes from both sides.

 **Copy change from left to right and**  **Copy change from right to left**

Replaces the content of a change from one side with the content of the corresponding change from the other side.

 **Remove change**

Rejects the change on the particular side and preserves the particular content on the other side.

Two-Way Diff Algorithms

Oxygen XML Editor offers the following two-way diff algorithms to compare files or fragments:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Characters** - Computes the differences at character level, meaning that it compares two files or fragments looking for identical characters. This algorithm is not available when the file comparison is in **Author** mode.
- **Words** - Computes the differences at word level, meaning that it compares two files or fragments looking for identical words. This algorithm is not available when the file comparison is in **Author** mode.
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **Syntax Aware** - Computes differences for known file types or fragments. This algorithm splits the files or fragments into sequences of *tokens* and computes the differences between them. The meaning of a *token* depends on the type of compared files or fragments.

  Known file types include those listed in the **New** dialog box, such as XML file types (XSLT files, XSL-FO files, XSD files, RNG files, NVDL files, etc.), XQuery file types (`.xquery`, `.xq`, `.xqy`, `.xqm` extensions), DTD file types (`.dtd`, `.ent`, `.mod` extensions), TEXT file type (`.txt` extension), or PHP file type (`.php` extension).

  For example:

  - When comparing XML files or fragments, a token can be one of the following:
    - The name of an XML tag
    - The < character
    - The /> sequence of characters
    - The name of an attribute inside an XML tag
    - The = sign
    - The " character
    - An attribute value
    - The text string between the start tag and the end tag (a text node that is a child of the XML element corresponding to the XML tag that encloses the text string)

- When comparing plain text, a token can be any continuous sequence of characters or any continuous sequence of whitespaces, including a new line character.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Three-Way Comparisons

Oxygen XML Editor also includes a three-way comparison feature to help you solve conflicts and merge changes between multiple modifications. It is especially helpful for teams who have multiple authors editing and committing the same documents. It provides a comparison between a local change, another change, and the original base revision. Some additional advantages include:

- Visualize and merge content that was modified by you and another member of your team.
- Marks differences correctly even when the document structure is rearranged.
- Allows you to merge XML-relevant modifications.

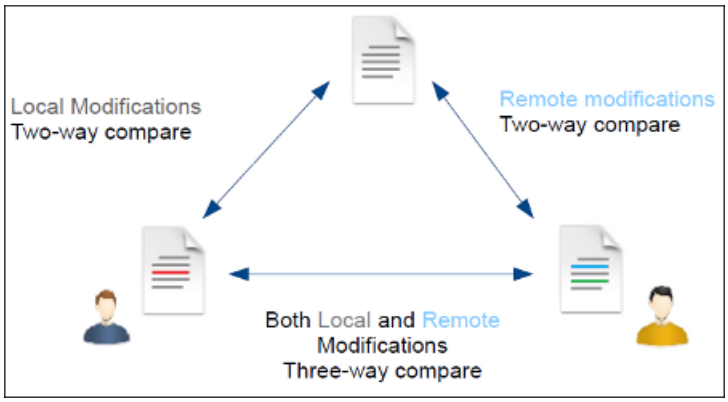

Figure 775: Three-Way Comparison

Compare Files

To perform a three-way comparison, follow these steps:

1. Open a file in the left panel and the file you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down menu.

   Step Result: The selected files are opened in the two side-by-side editors. A text editing mode is used to offer a better view of the differences.
2. Click the **Three-Way Comparison** button on the toolbar and select the base file in the **Base** field. You can specify the path by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down menu.
3. To highlight the differences, click the **Perform File Differencing** button on the toolbar.
4. You can use the drop-down menu on the left side of the toolbar to change the *algorithm* for the operation.
5. You can also use the **Diff Options** button to access the **Files Comparison** preferences page where you can choose to ignore certain types of markup and configure various options.

The resulting comparison will show you differences between the two files, as well as differences between either of them and the base (ancestor) file. The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes.

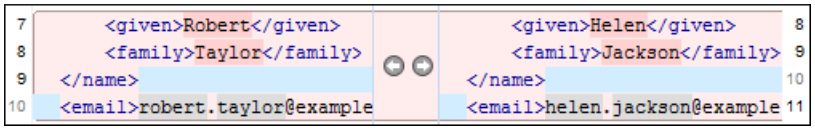

Figure 776: Three-Way Differences

Highlighting Colors

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the ***Files Comparison / Appearance*** *preferences page*, but the default colors and their shades mean the following:

- **Pink** - Identifies blocks of changes that include conflicts.
- **Gray** - Identifies your outgoing changes that do not include conflicts.
- **Blue** - Identifies incoming changes that do not include conflicts.
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Navigate Differences

To navigate through differences, do one of the following:

- Use the navigation buttons on the toolbar (or in the **Compare** menu).
- Select a block of differences by clicking its small colored marker in the overview ruler located in the right-most part of the window. At the top of the overview ruler there is a success indicator that turns green where there are no differences, or red if differences are found.
- Click a colored area in between the two text editors.

Editing Actions

You can edit the files directly in either editing pane. The two editors are constantly synchronized and the differences are refreshed when you save the modified document or when you click the  **Perform File Differencing** button.

A variety of actions are available on the *toolbar* and in the *various menus* (these same actions are also available in the contextual menu in both editing panes). The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

Append left change to right and Append right change to left

Copies the content of the selected change from one side and appends it on the other, according to the content of the corresponding change. As a result, the side where the arrow points to will contain the changes from both sides.

Copy change from left to right and Copy change from right to left

Replaces the content of a change from one side with the content of the corresponding change from the other side.

Remove change

Rejects the change on the particular side and preserves the particular content on the other side.

Three-Way Diff Algorithms

Oxygen XML Editor offers the following three-way diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Second Level Comparisons

For both two-way and three-way comparisons, Oxygen XML Editor automatically performs a second level comparison for the **Lines**, **XML Fast**, and **XML Accurate** algorithms. After the first comparison is finished, the second level comparisons for the **Lines** algorithm is processed on text nodes using a word level comparison, meaning that it looks for identical words. For the **XML Fast** and **XML Accurate** algorithms, the second level

comparison is processed using a *syntax-aware comparison*, meaning that it looks for identical *tokens*. This second level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

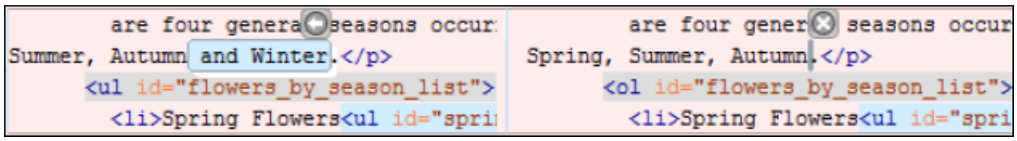

Figure 777: Second Level Diff Comparison

Note: If a modified text fragment contains XML markup (such as processing instructions, XML comments, CData, or elements), the second level comparison will not automatically be performed. In this case you can manually select a second level comparison by doing a word level or character level comparison.

To do a word level comparison, select **Show word level details** from the contextual menu or **Compare** menu.

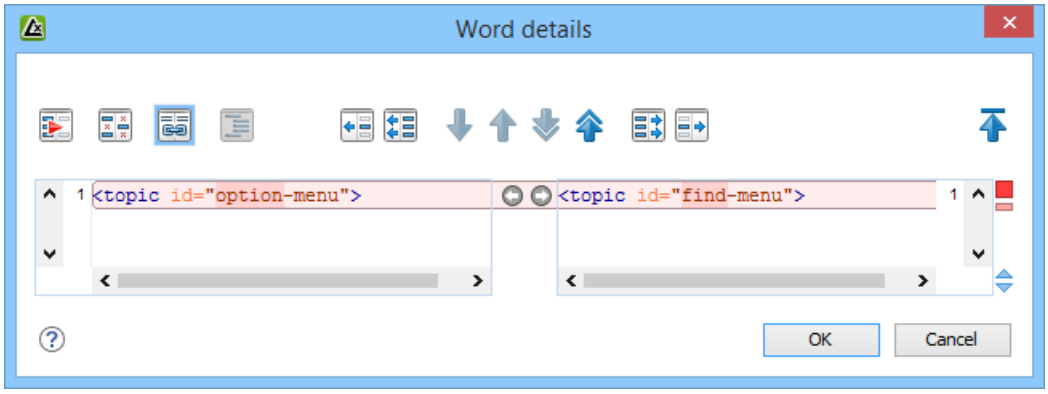

Figure 778: Word Level Comparison

To do a character level comparison, select **Show Character Level details** from the contextual menu or **Compare** menu.

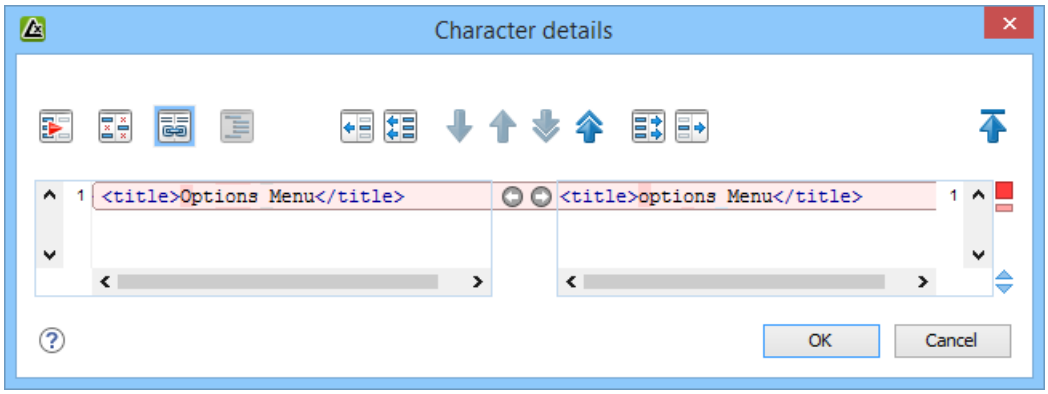

Figure 779: Character Level Comparison

Author Visual Mode

The **Compare Files** tool includes an **Author** mode that displays the files in a visual mode similar to the **Author** editing mode in Oxygen XML Editor/Author. This makes it easier to see how the compared changes will look in the final output. This visual mode is available when the compared files are detected as being XML. To determine whether the files are initially opened in the merge tool's **Text** or **Author** mode, it detects the ***Initial Edit Mode*** *in the Document Type Association configuration* and the mode the files were last opened in Oxygen XML Editor/Author.

Note: This mode is not available if the ***Enable file comparison in Author mode*** *option* is not selected in the **Diff** > **Files Comparison** preferences page.

This visual mode includes unique features such as a ***Tags Display Mode*** *drop-down button* on the toolbar that allows you to select the amount of tags to display in this visual mode. This mode also presents differences that were made using the **Track Changes** feature (although the **Track Changes** feature is not available in the comparison tool).

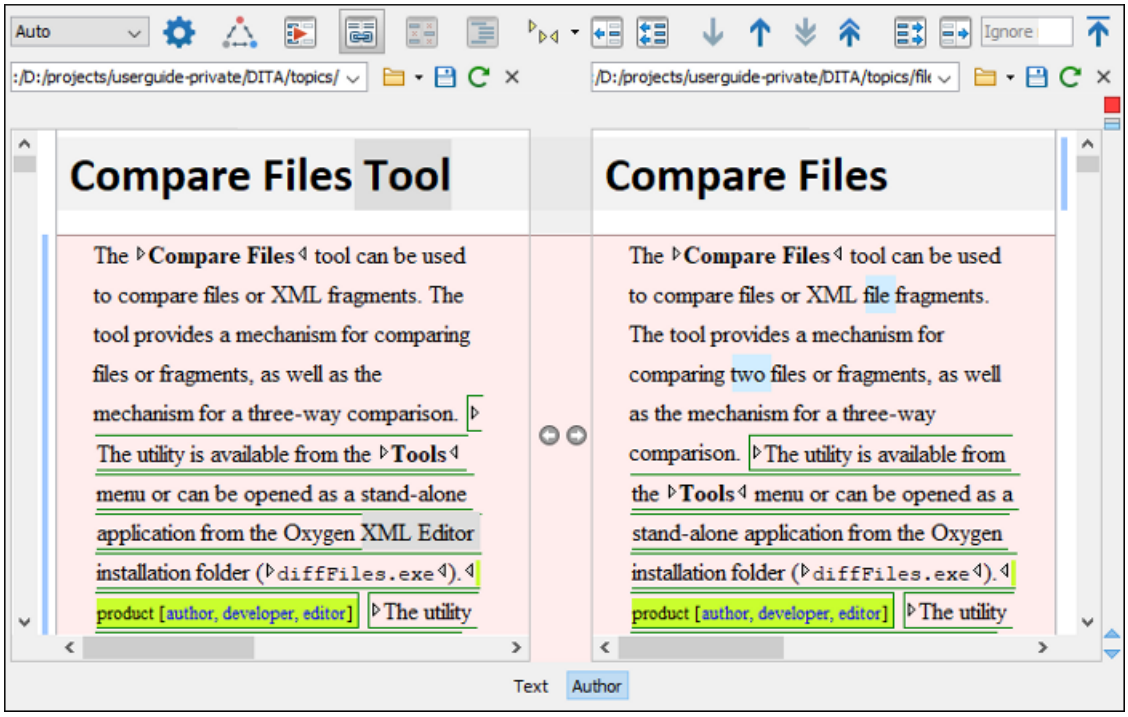

Figure 780: File Comparison Tool - Author Mode

Author Mode Algorithms

The visual **Author** mode offers the following diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Second Level Comparisons

The visual **Author** mode automatically performs a second level comparison for the **XML Fast** and **XML Accurate** algorithms. After the first comparison is finished, the second level comparisons is processed on text nodes using a word level comparison, meaning that it looks for identical words. This second level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

Compare Directories on page 961

Starting File Comparison Tool from a Command Line

The file comparison tool can be started by using command-line arguments. In the installation folder there is an executable shell (`diffFiles.bat` on Windows, `diffFiles.sh` on OS X and Linux). To specify the files to compare, you can pass command-line arguments using the following construct: `diffFiles.bat/diffFiles.sh [path to left file] [path to right file] [path to 3-way base file]`.

If three files are specified, the tool will start in the *3-way comparison mode*. If only two files are specified, the tool will start in the *2-way comparison mode*. The first specified file will be added to the left panel in the comparison

tool, the second file to the right panel, and the optional third file will be the base (ancestor) file used for a 3-way comparison. If you pass only one argument, you are prompted to manually choose another file.

If you want to launch the file comparison tool from an external application with specified files and you want the file browsing tools at the top of both panels to be hidden, you should use the `-ext` argument as the first command. There are some additional arguments that are allowed and to see all the details for the command line construct, type `diffFiles.bat --help` in the command line.

Example:

To do a 3-way comparison, the command line might look like this:

Windows

```
diffFiles.bat "c:\docs\file 1" "c:\docs\file 2" c:\docs\basefile
```

Tip: If there are spaces in the path names, surround the paths with quotes.

Linux

```
diffFiles.sh home/file1 home/file2 home/basefile
```

Mac OS X

```
diffFiles.sh documents/file1 documents/file2 documents/basefile
```

How to Integrate the File Comparison Tool with Git

The file comparison tool can be integrated with Git clients. It requires that you configure your `.gitconfig` file and then you can simply start the tool from the command line.

To integrate the **Compare Files** tool with your Git client, follow this procedure:

1. Use one of the following methods to instruct your Git client to use the Oxygen **Compare Files** tool:
   - **Manual Configuration** - Locate your Git user-specific configuration file (`.gitconfig`) and edit it with a text editor (for example, in Windows, the `.gitconfig` file is most likely located in your user home directory). Add (or replace) the following lines:

     ```
     [diff]
         tool = oxygendiff
     [merge]
         tool = oxygendiff
     [difftool "oxygendiff"]
         cmd = '[pathToOxygenInstallDir]/diffFiles.exe' -ext $REMOTE $LOCAL $LOCAL
     [mergetool "oxygendiff"]
         cmd = '[pathToOxygenInstallDir]/diffFiles.exe' -ext $LOCAL $REMOTE $BASE $MERGED
         trustExitCode = true
     [difftool]
         prompt = false
     ```

     Note: For Mac OS X, the **cmd** lines would start with something like: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**. For Linux, the **cmd** lines would start with something like: **sh "/Oxygen XML Editor/diffFiles.sh"**.
   - **Command Line Configuration** - To automatically configure the `.gitconfig` file, you can run the following commands from a command line:

     ```
     git config --global diff.tool oxygendiff
     git config --global difftool.oxygendiff.cmd '[Oxygen install dir]/diffFiles.exe -ext
     $REMOTE $LOCAL $LOCAL'
     git config --global merge.tool oxygendiff
     git config --global mergetool.oxygendiff.cmd '[Oxygen install dir]/diffFiles.exe
     -ext $LOCAL $REMOTE $BASE $MERGED'
     git config --global mergetool.oxygendiff.trustExitCode true
     ```

     Note: For Mac OS X, the Oxygen file comparison tool would be specified in the second and fourth commands with something like: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**. For Linux, it would be something like: **sh "/Oxygen XML Editor/diffFiles.sh"**.
2. To start the **Compare Files** tool and see a comparison of changes for a particular file, run the following command from a command line:

   ```
   git difftool [PathToFile]
   ```

Tip: If the file you want to compare has conflicts, you can start the **Compare Files** tool as a *merge conflict resolution* tool by running the following command:

```
git mergetool [PathToFile]
```

For more information about the Git *difftool* syntax, see *https://git-scm.com/docs/git-difftool*.

For more information about the Git *mergetool* syntax, see *https://git-scm.com/docs/git-mergetool*.

How to Integrate the File Comparison Tool with SourceTree

The file comparison tool can be integrated with SourceTree so that you can use it to compare changes. The advantages of doing this include:

- The Oxygen **Compare Files** tool presents the files side-by-side and makes it much easier to determine real changes.
- The Oxygen **Compare Files** tool includes XML comparison algorithms.
- The Oxygen **Compare Files** tool includes various options for configuring the comparison.
- The Oxygen **Compare Files** tool allows you to navigate through changes.

To integrate the **Compare Files** tool with SourceTree, follow this procedure, depending on your operating system:

Windows

1. In SourceTree, go to **Tools** > **Options**.
2. Go to the **Diff** tab.
3. In the **External Diff/Merge** section, configure the settings as follows:
   - **External Diff Tool** - Select **Custom**.
   - **Diff Command** - Enter the path of the Oxygen `diffFile.exe` file (for example: `c:\Programs\Oxygen XML Editor 19\diffFiles.exe`).
   - **Arguments** - Enter **-ext $REMOTE $LOCAL $LOCAL**.
   - **Merge Tool** - Select **Custom**.
   - **Diff Command** - Enter the path of the Oxygen `diffFile.exe` file (for example: `c:\Programs\Oxygen XML Editor 19\diffFiles.exe`).
   - **Arguments** - Enter **-ext $LOCAL $REMOTE $BASE $MERGED**.
4. Click **OK**.

   Result: In SourceTree, you can now compare file changes with the Oxygen **Compare Files** tool by simply selecting **External Diff** from the contextual menu, **Actions** menu, or **Ctrl+D**.

Mac OS X

1. In SourceTree, go to **SourceTree** > **Preferences**.
2. Go to the **Diff** tab.
3. In the **External Diff/Merge** section, configure the settings as follows:
   - **External Diff Tool** - Select **Custom**.
   - **Diff Command** - Enter a command line argument to launch the Oxygen `diffFiles.sh` file (for example: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**).
   - **Arguments** - Enter **-ext $REMOTE $LOCAL $LOCAL**.
   - **Merge Tool** - Select **Custom**.
   - **Diff Command** - Enter a command line argument to launch the Oxygen `diffFiles.sh` file (for example: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**).
   - **Arguments** - Enter **-ext $LOCAL $REMOTE $BASE $MERGED**.
4. Close the preferences dialog box.

   Result: In SourceTree, you can now compare file changes with the Oxygen **Compare Files** tool by simply selecting **External Diff** from the contextual menu or **Actions** menu.

Toolbar and Contextual Menu Actions of the Compare Files Tool

The toolbar of the **Compare Files** tool contains operations that can be performed on the source and target files or XML fragments. Many of the actions are also available in the contextual menu.

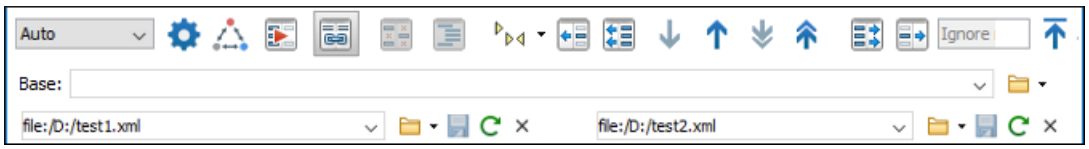

Figure 781: Compare Toolbar

The following actions are available:

Algorithm

This drop-down menu allows you to select one of the following diff algorithms (depending on whether it is a two-way or three-way comparison):

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Characters** - Computes the differences at character level, meaning that it compares two files or fragments looking for identical characters. This algorithm is not available when the file comparison is in **Author** mode.
- **Words** - Computes the differences at word level, meaning that it compares two files or fragments looking for identical words. This algorithm is not available when the file comparison is in **Author** mode.
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **Syntax Aware** - Computes differences for the file types or fragments known by Oxygen XML Editor, taking the syntax (the specific types of tokens) into consideration. This algorithm is not available when the file comparison is in **Author** mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Diff Options

Opens the ***Files Comparison*** *preferences page* where you can configure various options.

Three-Way Comparison

Toggle action that allows you to perform a three-way comparison between the two files displayed in the two editing panes and a base (ancestor) file.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Synchronized scrolling

Toggles synchronized scrolling on or off so that a selected difference can be seen on both sides of the application window. This option is on by default.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces. This option is not available when the file comparison is in **Author** mode.

Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on OS X))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences. This option is not available when the file comparison is in **Author** mode.

Note: When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Tags Display Mode

Allows you to select the amount of markup to be displayed in the ***Author*** *visual mode*. You can choose between: **Full Tags with Attributes**, **Full Tags**, **Block Tags**, **Inline Tags**, **Partial Tags**, or **No Tags**.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Copy All Changes from Left to Right

Copies all changes from the file in the left panel to the file in the right panel.

Copy Change from Left to Right

Copies the selected difference from the file in the left panel to the file in the right panel.

Ignore Nodes by XPath

You can use this text field to enter an *XPath expression* to ignore certain nodes from the comparison. It will be processed as XPath version 2.0. You can also enter the name of the node to ignore all nodes with the specified name (for example, if you want to ignore all ID attributes from the document, you could simply enter `@id`). This field is only available when comparing XML documents using the **XML Fast** or **XML Accurate** algorithms.

Note: If an XPath expression is specified in the ***Ignore nodes by XPath*** *option* in the **Diff / File Comparison** preferences page, that one is used as a default when the application is started. If you then enter an expression in this field on the toolbar, this one will be used instead of the default. If you delete the expression from this field, neither will be used.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Base

Available for *three-way comparisons*. It is the base file that will be compared with the files opened in the left and right editors. You can specify the path to the file by using the text field, its history drop-down, or the browsing tools in the **Browse** drop-down menu.

Left-Side (Source) File

You can specify the path to the file to be compared on the left side (source) by using the text field, its history drop-down, or the browsing tools in the **Browse** drop-down menu.

Save

Saves the changes made in the source (left-side) file.

Reload

Reloads the source (left-side) file.

Close

Closes the source (left-side) file.

Right-Side (Target) File

You can specify the path to the file to be compared on the right side (target) by using the text field, its history drop-down, or the browsing tools in the **Browse** drop-down menu.

Save

Saves the target (right-side) file.

Reload

Reloads the target (right-side) file.

Close

Closes the target (right-side) file.

Compare Files Tool Menus

The menus in the **Compare Files** tool contain some of the same actions that are on the toolbar, as well as some common actions that are identical to the same actions in the Oxygen XML Editor menus. The menu actions include:

File Menu

Source > Open

Browses for a file that will be displayed in the left panel.

Source > Open URL

Browses for a remote file that will be displayed in the left panel.

Source > Open File from Archive

Browses an archive for a file that will be displayed in the left panel.

Source > Reload

Reloads the file in the left panel.

Source > Save

Saves the changes made to the file in the left panel.

Source > Save As

Allows you to choose a destination to save the file in the left panel.

Source > Close

Closes the file in the left panel.

Target > Open

Browses for a file that will be displayed in the right panel.

Target > Open URL

Browses for a remote file that will be displayed in the right panel.

Target > Open File from Archive

Browses an archive for a file that will be displayed in the right panel.

Target > Reload

Reloads the file in the right panel.

Target > Save

Saves the changes made to the file in the right panel.

Target > Save As

Allows you to choose a destination to save the file in the right panel.

Target > Close

Closes the file in the right panel.

Base > Open

Browses for a file that will be compared with both files in a *three-way comparison*.

Base > Open URL

Browses for a remote file that will be compared with both files in a *three-way comparison*.

Base > Open File from Archive

Browses an archive for a file that will be compared with both files in a *three-way comparison*.

Close (Ctrl + W (Command + W on OS X))

Closes the application.

Edit Menu

Cut

Cut the selection from the currently focused editor panel to the clipboard.

Copy

Copy the selection from the currently focused editor panel to the clipboard.

Paste

Paste content from the clipboard into the currently focused editor panel.

Select all

Selects all content in the currently focused editor panel.

Undo

Undo changes in the currently focused editor panel.

Redo

Redo changes in the currently focused editor panel.

Find Menu

Find/Replace

Perform *find/replace* operations in the currently focused editor panel.

Find Next

Go to the next match using the same options as the last *find* operation. This action runs in both editor panels.

Find Previous

Go to the previous match using the same options as the last *find* operation. This action runs in both editor panels.

Compare Menu

Three-Way Comparison

Toggle action that allows you to perform a three-way comparison between the two files displayed in the two editing panes and a base (ancestor) file.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Last Change (Ctrl + E (Command + E on OS X))

Jumps to the last change.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Copy All Changes from Left to Right

Copies all changes from the file in the left panel to the file in the right panel.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy Change from Left to Right

Copies the selected difference from the file in the left panel to the file in the right panel.

Show Word Level Details

Provides a word-level comparison of the selected change.

Show Character Level Details

Provides a character-level comparison of the selected change.

Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on OS X))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

Note: When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Options Menu

Preferences

Opens the preferences dialog box that includes numerous pages of options that can be configured.

Menu Shortcut Keys

Opens the **Menu Shortcut Keys** option page where you can configure keyboard shortcuts available for menu items.

Reset Global Options

Resets options to their default values. Note that this option appears only when the tool is executed as a stand-alone application.

Import Global Options

Allows you to import an options set that you have previously exported.

Export Global Options

Allows you to export the current options set to a file.

Help Menu

Help (F1)

Opens a **Help** dialog box that displays the User Manual at a section that is appropriate for the context of the current cursor position.

Use Online Help

If this option is selected, when you select Help or press F1 while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Report problem

Opens a dialog box that allows the user to write the description of a problem that was encountered while using the application. You can change the URL where the reported problem is sent by using the `com.oxygenxml.report.problems.url` system property. The report is sent in XML format through the `report` parameter of the POST HTTP method.

Support Center

Opens the Oxygen XML Editor Support Center web page in a browser.

Compare Directories

The **Compare Directories** tool can be used to compare and manage changes to files and folders within the structure of your directories. The utility is available from the **Tools** menu or can be opened as a stand-alone application from the Oxygen XML Editor installation folder (`diffDirs.exe`).

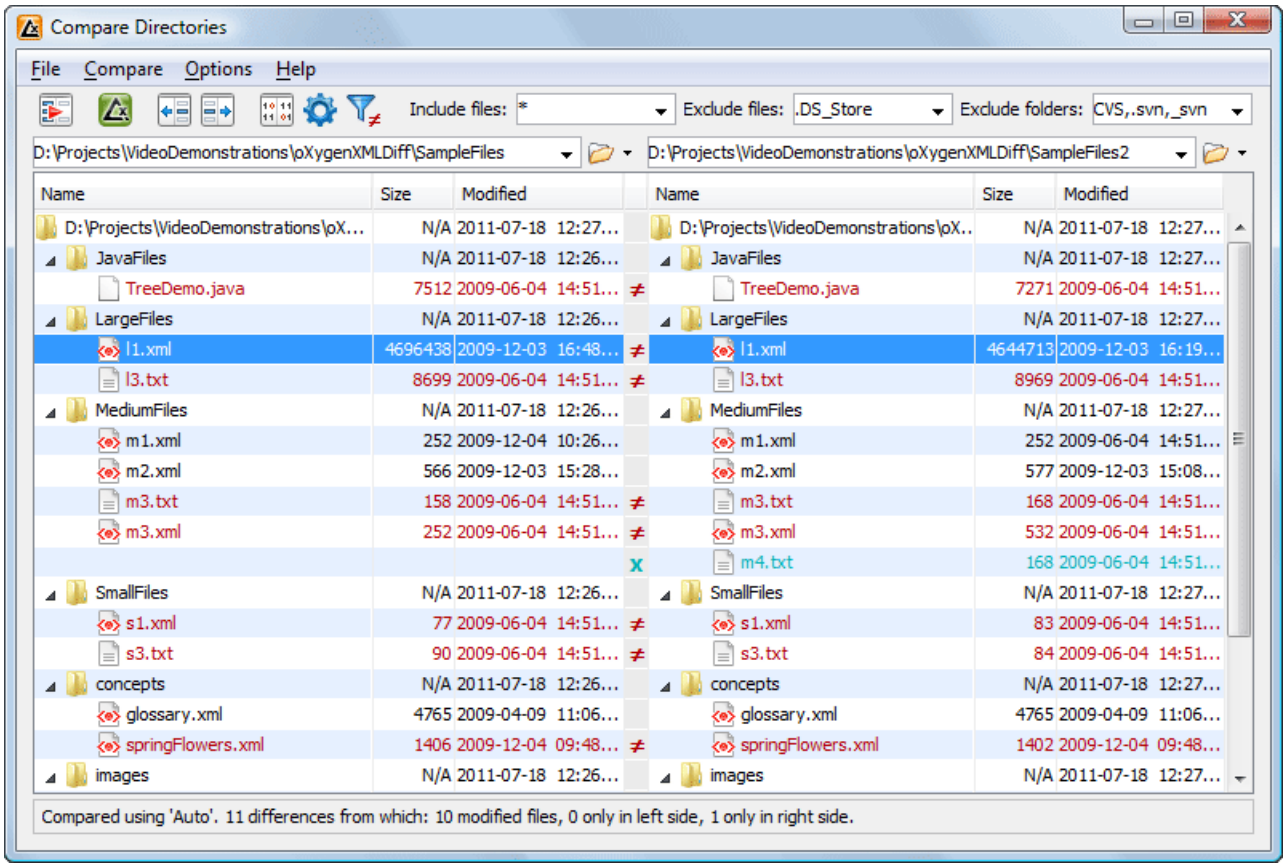

Figure 782: Compare Directories Tool

Starting the Tool from a Command Line

The directory comparison tool can also be started by using command-line arguments. In the installation folder there is an executable shell (`diffDirs.bat` on Windows, `diffDirs.sh` on OS X and Linux). To specify the directories to compare, you can pass command-line arguments using the following construct: `diffDirs.bat/diffDirs.sh [directory path 1] [directory path 2]`.

If you pass only one argument, you are prompted to manually choose the second directory or archive.

Example:

To do a comparison between two directories, the command line would look like this:

Windows

```
diffDirs.bat "c:\documents new" "c:\documents old"
```

Tip: If there are spaces in the path names, surround the paths with quotes.

Linux

```
diffDirs.sh home/documents1 home/documents2
```

Mac OS X

```
diffDirs.sh documents1 documents2
```

Directory Comparisons

To perform a directory comparison, follow these steps:

1. Select a folder in the left panel and the folder you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the **Browse for local directory** action in the **Browse** drop-down menu.

Step Result: The selected directory structures are opened in the two side-by-side panels.

2. To highlight the differences between the two folders, click the **Perform Directories Differencing** button from the toolbar.
3. You can also use the **Diff Options** button to access the ***Directories Comparison*** *preferences page* where you can configure various options.

To compare the content of two archives, follow these steps:

1. Use the **Browse for archive file** action in the **Browse** drop-down menu to select the archives in the left and right panels.
2. By default, the supported archives are not treated as directories and the comparison is not performed on the files inside them. To make Oxygen XML Editor treat supported archives as directories, select the ***Look in archives*** *option* in the **Directories Comparison** preferences page.
3. To highlight the differences, click the **Perform Directories Differencing** button from the toolbar.

The directory comparison results are presented using two tree-like structures showing the files and folders, including their name, size, and modification date. A column that contains graphic symbols separates the two tree-like structures. The graphic symbols can be one of the following:

- An **X** symbol, when a file or a folder exists in only one of the compared directories.
- A ≠symbol, when a file exists in both directories but the content differs. The same sign appears when a collapsed folder contains differing files.

The color used for the symbol and the directory or file name can be customized in the ***Directories Comparison / Appearance*** *preferences page*. You can double-click lines marked with the ≠ symbol to open a **Compare Files** window, which shows the differences between the two files.

The directories that contain files that differ are expanded automatically so that you can focus directly on the differences. You can merge the contents of the directories by using the copy actions. If you double-click (or press **Enter**) on a line with a pair of files, Oxygen XML Editor starts a *file comparison* between the two files, using the **Compare Files** tool.

Related Information:

Compare Files on page 1646

Toolbar and Contextual Menu Actions of the Compare Directories Tool

The toolbar of the **Compare Directories** tool contains operations that can be performed on the compared directory structure. Some of the toolbar actions are also available in the contextual menu.

Figure 783: Compare toolbar

Toolbar Actions

Perform Directories Differencing

Looks for differences between the two directories displayed in the left and right side of the application window.

Perform Files Differencing

Opens the ***Compare Files*** *tool* that allows you to compare the currently selected files.

Copy Change from Right to Left

Copies the selected change from the right side to the left side (if there is no file/folder in the right side, the left file/folder is deleted).

 **Copy Change from Left to Right**

Copies the selected change from the left side to the right side (if there is no file/folder in the left side, the right file/folder is deleted).

 **Binary Compare**

Performs a byte-level comparison on the selected files.

 **Diff Options**

Opens the ***Directory Comparison*** *preferences page* where you can configure various options.

 **Show Only Modifications**

Displays a more uncluttered file structure by hiding all identical files.

File and folder filters

Differences can be filtered using three combo boxes: **Include files**, **Exclude files**, and **Exclude folders**. They come with predefined values and are editable to allow custom values. All of them accept multiple comma-separated values and the ***** and **?** wildcards. For example, to filter out all JPEG and GIF image files, edit the **Exclude files** filter box to read **`*.jpeg, *.png`**. Each filter includes a drop-down menu with the latest 15 filters applied.

Contextual Menu Actions

 **Perform Files Differencing**

Opens the ***Compare Files*** *tool* that allows you to compare the currently selected files.

 **Binary Compare**

Performs a byte-level comparison on the selected files.

 **Copy Change from Right to Left**

Copies the selected difference from the file in the right panel to the file in the left panel.

 **Copy Change from Left to Right**

Copies the selected difference from the file in the left panel to the file in the right panel.

Open

If the action is invoked on a file, the selected file is opened in Oxygen XML Editor. If the action is invoked on a directory, the selected directory is opened in the default file browser for your particular operating system.

Open in System Application

Opens the selected file in the system application that is associated with that type of file. The action is available when launching the **Compare Directories** tool from the **Tools** menu in Oxygen XML Editor.

Show in Explorer

Opens the default file browser for your particular operating system with the selected file highlighted.

Compare Directories Tool Menus

The menus in the **Compare Directories** tool contain some of the same actions that are on the toolbar, as well as some common actions that are identical to the same actions in the Oxygen XML Editor menus. The menu actions include:

File Menu

Close (Ctrl + W (Command + W on OS X))

Closes the application.

Compare Menu

Perform Directories Differencing

Looks for differences between the two directories displayed in the left and right side of the application window.

Perform Files Differencing

Opens the ***Compare Files*** *tool* that allows you to compare the currently selected files.

Copy Change from Right to Left

Copies the selected change from the right side to the left side (if there is no file/folder in the right side, the left file/folder is deleted).

Copy Change from Left to Right

Copies the selected change from the left side to the right side (if there is no file/folder in the left side, the right file/folder is deleted).

Options Menu

Preferences

Opens the preferences dialog box that includes numerous pages of options that can be configured.

Menu Shortcut Keys

Opens the **Menu Shortcut Keys** option page where you can configure keyboard shortcuts available for menu items.

Reset Global Options

Resets options to their default values. Note that this option appears only when the tool is executed as a stand-alone application.

Import Global Options

Allows you to import an options set that you have previously exported.

Export Global Options

Allows you to export the current options set to a file.

Help Menu

Help (F1)

Opens a **Help** dialog box that displays the User Manual at a section that is appropriate for the context of the current cursor position.

Use Online Help

If this option is selected, when you select Help or press F1 while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Report problem

Opens a dialog box that allows the user to write the description of a problem that was encountered while using the application. You can change the URL where the reported problem is sent by using the `com.oxygenxml.report.problems.url` system property. The report is sent in XML format through the `report` parameter of the POST HTTP method.

Support Center

Opens the Oxygen XML Editor Support Center web page in a browser.

Compare Images

You can use the **Compare Directories** tool to compare images. If you double-click a line that contains two different images, the **Compare images** window is displayed. This dialog box presents the images in the left and right sides, scaled to fit the available view area. You can use the contextual menu actions to scale the images to their original size or scale them down to fit in the view area.

The supported image types are: *GIF*, *JPG*, *JPEG*, *PNG*, and *BMP*.

Compare Directories Against a Base (3-Way)

The **Compare Directories Against a Base (3-way)** tool allows you to perform three-way comparisons on directories to help you identify and merge changes between multiple modifications of the same directory structure. It is especially helpful for teams that have multiple authors contributing documents to the same directory system. It offers information about conflicts and changes, and includes actions to easily merge, accept, overwrite, or ignore changes to the directory system.

How to Perform 3-Way Directory Comparisons

To perform a 3-way directories comparison, follow these steps:

1. Select **Compare Directories Against a Base (3-way)** from the **Tools** menu.

   Step Result: This opens a dialog box that allows you to select the 3 file sets that will be used for the comparison.

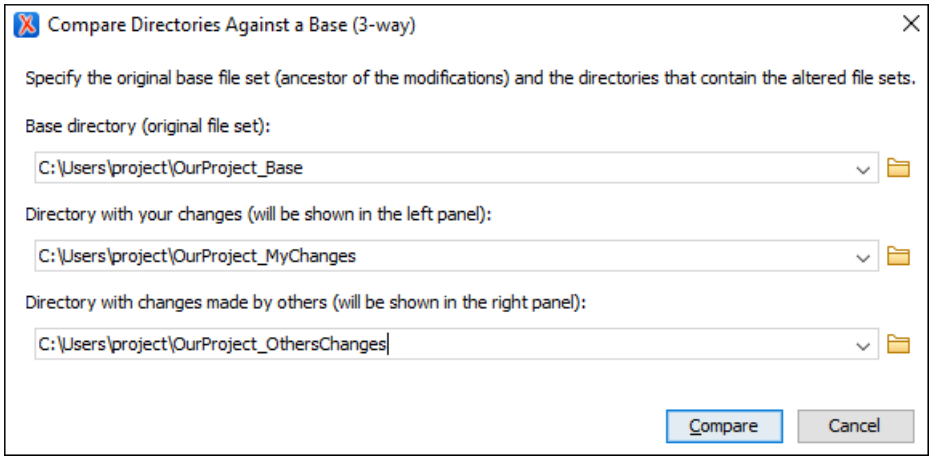

Figure 784: Compare Directories Against a Base File Set Chooser

2. Select the file sets to be compared:
   - **Base directory** - This is the original (base) file set before any modifications were made by your or others.
   - **Directory with your changes** - This is the file set with changes that you have made. This file set will be displayed in the left panel in the comparison tool.
   - **Directory with changes made by others** - This is the file set with changes made by others that you want to merge with your changes. This file set will be displayed in the right panel in the comparison tool.
3. Click the **Compare** button to compare the file sets and open the comparison and merge tool.
4. Use the features and actions described in the next section to identify and merge the changes.

3-Way Directory Comparison and Merge Tool

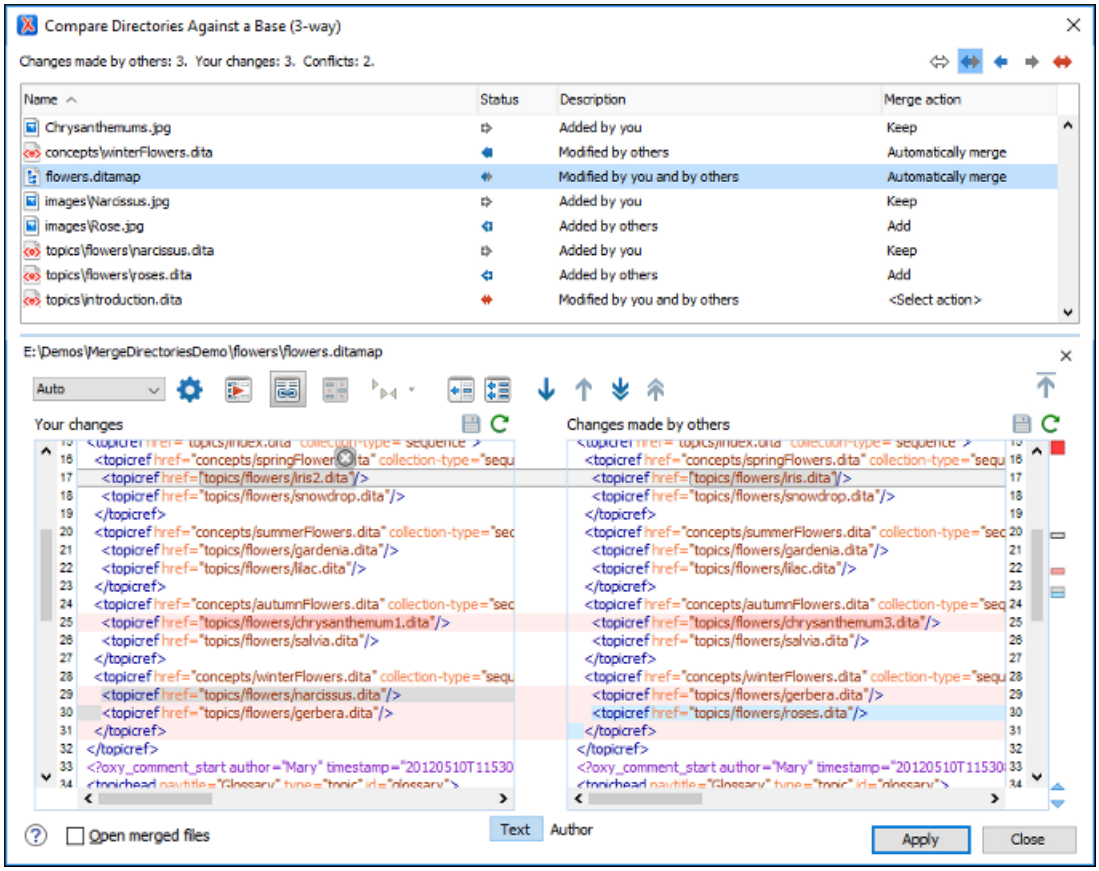

Figure 785: Comparison and Merge Tool

The 3-way directory comparison and merge tool includes the following information, features, and actions:

Number of Changes and Conflicts

The first thing you see in top-left corner of the tool is grand total of all the changes made by others, changes made by you, and the number of conflicts.

Filter Buttons

In the top-right corner you can use the toggle buttons to filter the list of modifications:

Show all files

Use this button to show all modified and unmodified files, as well as conflicts.

Show only files modified by you and others

Filters the list to show all files that have been modified, including conflicts.

Show only files modified by others

Filters the list to only show the files that were modified by others.

Show only files modified by you

Filters the list to only show the files that were modified by you.

Show only conflicting files

Filters the list to only show files that contain conflicts.

List of Files Panel

This panel shows the list of files in the compared file sets based upon the filter button that is selected. This panel includes the following sortable columns:

- **Name** - The file names.

- **Status** - An icon that represents the file status. Red icons indicate some sort of conflict. Gray icons indicate modifications made by you. Blue icons indicate modifications made by others.
- **Description** - A description of the file status.
- **Merge Action** - This column provides a drop-down menu for each file that allows you to choose some merge actions depending upon its status. A default action is always set to automatically merge the changes made by others with your changes. If there is a conflict, the default is **<Select action>** and you are required to make a selection. Click this column to access the drop-down menu where you can make a selection. The same actions are available in the contextual menu.

You can click a file to open it in the file comparison panel (the file from your file set is shown in the left panel while the file from the file set with changes made by others is shown in the right panel). For image files, the comparison panel shows a preview of the image. For other binary files, a preview is not available and you will just see its status.

File Comparison Panels

If you click a file in the top panel, the file is opened in this file comparison section. The file from your file set is shown in the left panel and the file from the other file set is shown in the right panel.

Note: If Oxygen XML Editor does not recognize the file type, a dialog box will be displayed that allows you to select the type of editor you want it to be associated with for this comparison (if you want Oxygen XML Editor to remember this association, you can select the **Associate file type with editor** option at the bottom of the dialog box).

This panel includes the following information and toolbar actions:

File Path

The first thing you see in this panel is the file path where merge actions will be applied if you make changes.

Close

Closes the file comparison panel.

Algorithm Drop-Down Menu

This drop-down menu allows you to select one of the following diff algorithms to be used for file comparisons:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Diff Options

Opens the ***Files Comparison*** *preferences page* where you can configure various options.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Synchronized scrolling

Toggles synchronized scrolling. When toggled on, a selected difference can be seen in both panels.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces. This option is not available when the file comparison is in **Author** mode.

Tags Display Mode

Allows you to select the amount of markup to be displayed in the **Author** visual mode. You can choose between: **Full Tags with Attributes**, **Full Tags**, **Block Tags**, **Inline Tags**, **Partial Tags**, or **No Tags**.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Left-Side File (Your changes)

Above the panel you can see the file path and the following two buttons:

Save

Saves changes made to the file.

Reload

Reloads the file.

Right-Side File (Changes made by others)

Above the panel you can see the file path and the following two buttons:

Reload

Reloads the file.

Displaying Changes in the File Comparison Panels

The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes.

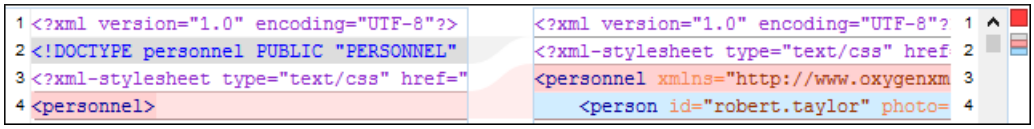

Figure 786: File Comparison Panels

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the ***Files Comparison / Appearance*** *preferences page*, but the default colors and their shades mean the following:

- **Pink** - Identifies modifications on either side.
- **Gray** - Identifies an addition of a node in the left side (your outgoing changes).
- **Blue** - Identifies an addition of a node in the right side (incoming changes).
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Direct Editing Actions in the File Comparison Panels

In addition to selecting merge actions from the drop-down menus in the **Merge Action** column in the top panel, you can also edit the files directly in the left pane (your local changes). The two editors are constantly synchronized and the differences are refreshed when you save the modified document (**Save** button or **Ctrl +S**) or when you click the **Perform File Differencing** button.

A variety of actions are available in the contextual menu in both editing panes. The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

Append right change to left

Copies the content of the selected change from the right side and appends it on the left side.

Copy change from right to left

Replaces the content of a change in the left side with the content of the change in the right side.

Remove change

Removes the change from the left side.

Any time you save manual changes (**Save** button or **Ctrl+S**), the selection in the **Merge Action** column in the top panel automatically changes to **Use merged** and a copy of the original file is kept so that you can revert to the original file if necessary. To discard your manual changes and revert to your original changes, select a different action in the **Merge Action** drop-down menu.

Open Merged Files

If you select this option, all the files that will be modified by the merge operation will be opened in the editor after the operation is finished.

Applying Changes

When you click the **Apply** button, all the merge actions you have selected and the changes you have made will be processed.

If there are unresolved conflicts (conflicts where no merge action is selected in the **Merge Action** drop-down menu), a dialog box will be displayed that allows you to choose how to solve the conflicts. You can choose between the following:

- **Keep your changes** - If you select this option and then click **Apply**, your local changes will be preserved for the unresolved conflicts.
- **Overwrite your changes** - If you select this option and then click **Apply**, your local changes will be overwritten with the changes made by others, for the unresolved conflicts.
- **Cancel** - You can click the **Cancel** button to go back to the merge tool to resolve the conflicts individually.

Cancelling Changes

If you click the **Cancel** button at the bottom of the merge tool, all the changes you made in the tool will be lost.

Author Visual Mode

The **Comparison and Merge** tool includes an **Author** mode that displays the files in a visual mode similar to the **Author** editing mode in Oxygen XML Editor/Author. This makes it easier to see how the compared changes will look in the final output. This visual mode is available when the compared files are detected as being XML. To

determine whether the files are initially opened in the merge tool's **Text** or **Author** mode, it detects the ***Initial Edit Mode*** *in the Document Type Association configuration* and the mode the files were last opened in Oxygen XML Editor/Author.

Note: This mode is not available if the ***Enable file comparison in Author mode*** *option* is not selected in the **Diff** > **Files Comparison** preferences page.

This visual mode includes unique features such as a ***Tags Display Mode*** *drop-down button* on the toolbar that allows you to select the amount of tags to display in this visual mode. This mode also presents differences that were made using the **Track Changes** feature (although the **Track Changes** feature is not available in the comparison tool).

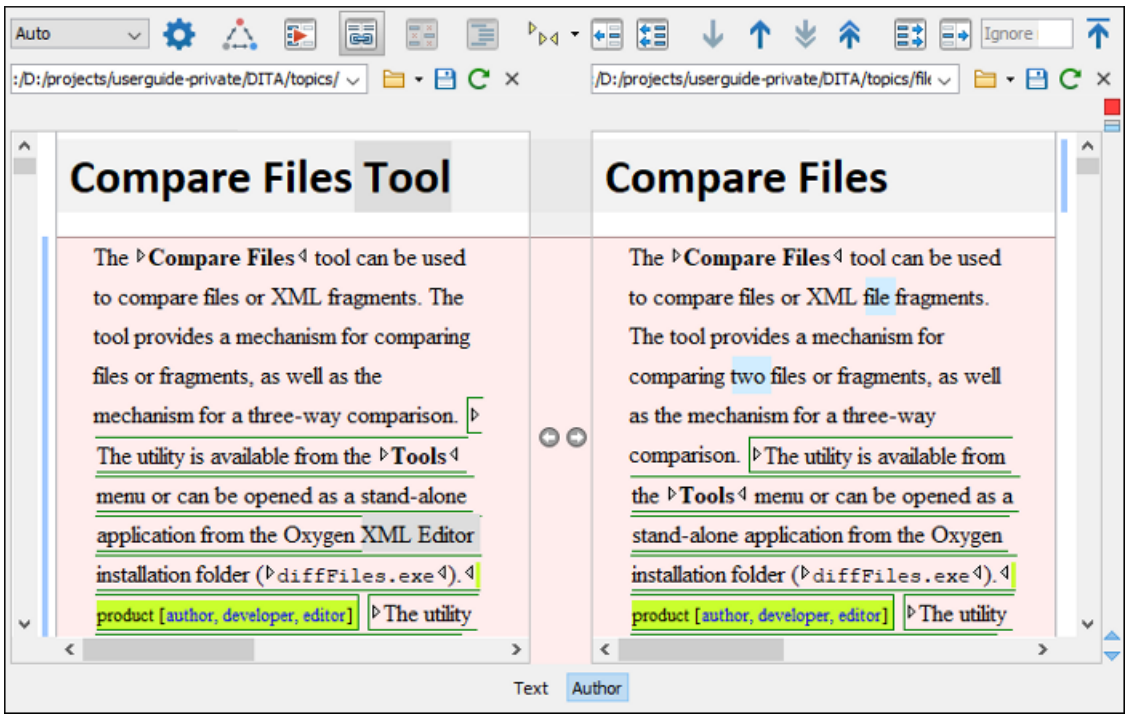

Figure 787: File Comparison Tool - Author Mode

Author Mode Algorithms

The visual **Author** mode offers the following diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Author Mode Second Level Comparisons

The visual **Author** mode automatically performs a second level comparison for the **XML Fast** and **XML Accurate** algorithms. After the first comparison is finished, the second level comparisons is processed on text nodes using a word level comparison, meaning that it looks for identical words. This second level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

Syncro SVN Client

The Syncro SVN Client is a client application for the Apache Subversion™ version control system, compatible with Subversion 1.6, 1.7, and 1.8 servers. It manages files and directories that change over time and are stored in a central repository. The version control repository is much like an ordinary file server, except that it remembers every change ever made to your files and directories. This allows you to access older versions of your files and examine the history of how and when your data changed.

To start Syncro SVN Client, go to **Tools** > **SVN Client**.

Main Window

This section explains the main window of Syncro SVN Client.

Views

The main window consists of the following views:

- ***Repositories*** *view* - Allows you to define and manage Apache Subversion™ repository locations.
- ***Working Copy*** *view* - Allows you to manage with ease the content of the working copy.
- ***History*** *view* - Displays information (author name, revision number, commit message) about the changes made to a resource during a specified period of time.
- ***Editor*** *view* - Allows you to edit various types of text files, with full syntax-highlight.
- ***Annotations*** *view* - Displays a list with information regarding the structure of a document (author and revision for each line of text).
- ***Compare*** *view* - Displays the differences between two revisions of a text file from the working copy.
- ***Image Preview*** *panel* - Allows you to preview standard image files supported by Syncro SVN Client: JPG, GIF and PNG.
- ***Compare Images*** *view* - Displays two images side by side.
- ***Properties*** *view* - Displays the SVN properties of a resource under version control.
- ***Console*** *view* - Displays information about the currently running operation, similar with the output of the Subversion command line client.
- ***Dynamic Help*** *view* - Shows information about the currently selected view.

The main window's status bar presents in the left side the operation in progress or the final result of the last performed action. In the right side there is a progress bar for the running operation and a stop button to cancel the operation.

SVN Main Menu

The main menu of the Syncro SVN Client is composed of the following menus:

File Menu

New submenu:

New File

This operation creates a new file as a child of the selected folder from the ***Repositories*** *view* tree or the ***Working Copy*** *view* tree, depending on the view that was last used. Note that for the ***Working Copy*** *view*, the file is added to *version control* only if the selected folder is under *version control*.

New Folder(Ctrl (Command on OS X) + Shift + F)

This operation creates a new folder as a child of the selected folder from the ***Repositories*** *view* tree or the ***Working Copy*** *view* tree, depending on the view that was last used. Note that for the ***Working Copy*** *view*, the file is added to *version control* only if the selected folder is under *version control*.

New External Folder (Ctrl (Command on OS X) + Shift + W)

This operation allows you to add a new external definition on the selected folder. An external definition is a mapping of a local directory to *a URL of a versioned directory*, and ideally a particular revision, stored in the `svn:externals` property of the selected folder.

Tip: You can specify a particular revision of the external item by using a *peg revision* at the end of the URL (for example, `URL@rev1234`). You can also use peg revisions to access external items that were deleted, moved, or replaced.

The URL used in the external definition format can be relative. You can specify the repository URL that the external folder points to by using one of the following relative formats:

- **../** - Relative to the URL of the directory that the `svn:externals` property is set.
- **^/** - Relative to the root of the repository in which the `svn:externals` property is versioned.
- **//** - Relative to the scheme of the URL of the directory that the `svn:externals` property is set.
- **/** - Relative to the root URL of the server in which the `svn:externals` property is versioned.

Important: To change the target URL of an external definition, or to delete an external item, do the following:

1. Modify or delete the item definition found in the `svn:externals` property that is set on the parent folder.
2. For the change to take effect, use the **Update** operation on the parent folder of the external item.

Note: Syncro SVN Client does not support definitions of local relative external items.

Open (Ctrl (Command on OS X) + O)

This action opens the selected file in an editor where you can modify it. The action is active only when a single item is selected. The action opens a file with the internal editor or the external application associated with that file type. This action works on any file selection from the ***Repositories** view*, ***Working Copy** view*, ***History** view*, or ***Directory Change Set** view*, depending on the view that was last used to invoke it. In the case of a folder, the action opens the selected folder with the system application for folders (for example, Windows Explorer on Windows or Finder on OS X, etc). Note that opening folders is available only for folders selected in the ***Working Copy** view*.

Open with(Ctrl (Command on OS X) + Shift + O)

Displays the **Open with** dialog box for specifying the editor in which the selected file is opened. If multiple files are selected only external applications can be used to open the files. This action works on any file selection from ***Repositories** view*, ***Working Copy** view*, ***History** view*, or ***Directory Change Set** view*, depending on the view that was last used to invoke it.

Show in Explorer/Show in Finder

Opens the parent directory of the selected working copy file and selects the file.

Save (Ctrl (Command on OS X) + S)

Saves the local file currently opened in the editor or the **Compare** view.

Save as

Saves any file selected in the **Repositories**, **History**, or **Directory Change Set** view.

Copy URL Location (Ctrl (Command on OS X) + Alt + U)

Copies the URL location of the resource currently selected in the **Repositories** view to clipboard.

Copy to

Copies the currently selected resource, either in **Repositories** or **Working copy** view, to a specified location.

Note: This action can also be used from **History** and **Directory Change Set** views to recover older versions of a repository item.

Move to(Ctrl (Command on OS X) + M)

Moves the currently selected resource, either in **Repositories** or **Working copy** view, to a specified location.

Rename(F2)

Renames the resource currently selected, either in **Repositories** or **Working copy** view.

Delete (Delete)

Deletes the resource currently selected either, in **Repositories** or **Working copy** view.

Locking:

- **Scan for locks (Ctrl (Command on OS X) + L)** - Contacts the repository and recursively obtains the list of locks for the selected resources. A dialog box containing the locked files and the lock description will be displayed. This is only active for resources under *version control*. For more details see *Scanning for locks*.
- **Lock (Ctrl (Command on OS X) + K)** - Allows you to lock certain files that need exclusive access. You can write a comment describing the reason for the lock and you can also force (*steal*) the lock. This action is active only on files under *version control*. For more details on the use of this action see *Locking a file*.
- **Unlock (Ctrl (Command on OS X) + Alt + K)** - Releases the exclusive access to a file from the repository. You can also choose to unlock it by force (*break the lock*).

Show SVN Properties (Ctrl (Command on OS X) + P)

Opens the ***Properties*** *view* and displays the SVN properties for a selected resource from ***Repositories*** *view* or ***Working Copy*** *view*, depending on the view that was last used to invoke it.

Show SVN Information (Ctrl (Command on OS X) + I)

Provides additional information for a selected resource. For more details, go to *Obtain information for a resource*.

Exit (Ctrl (Command on OS X) + Q)

Closes the application.

Edit Menu

Undo (Ctrl (Command on OS X) + Z)

Undo edit changes in the local file that is currently opened in the editor or the **Compare** view.

Redo (Ctrl (Command on OS X) + Y)

Redo edit changes in the local file that is currently opened in the editor or the **Compare** view.

Cut (Ctrl (Command on OS X) + X)

Cut selection from the local file that is currently opened in the editor view or the **Compare** view to clipboard.

Copy (Ctrl (Command on OS X) + C)

Copy selection from the local file that is currently opened in the editor or the **Compare** view to clipboard.

Paste (Ctrl (Command on OS X) + V)

Paste selection from clipboard into the local file that is currently opened in editor or the **Compare** view.

Find/Replace (Ctrl (Command on OS X) + F)

Perform find and replace operations in the local file that is currently opened in the editor or the **Compare** view.

Find Next (F3)

Go to the next match using the same find options of the last find operation. This action runs in the editor panel and in any non-editable text area (for example, the **Console** view).

Find Previous (Shift + F3)

Go to the previous match using the same find options of the last find operation. This action runs in the editor panel and in any non-editable text area (for example, the **Console** view).

Repository Menu

New Repository Location (Ctrl + Alt + N (Command + Alt + N on OS X))

Displays the **Add SVN Repository** dialog box. This dialog box allows you to define a new repository location.

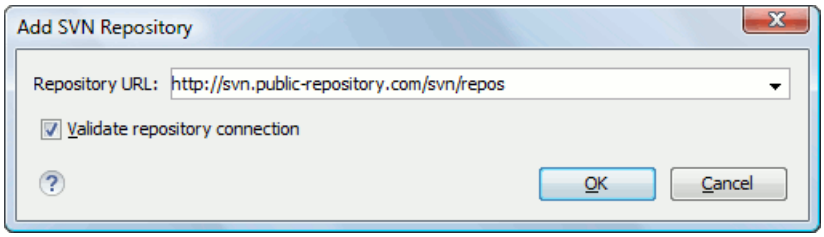

Figure 788: Add SVN Repository Dialog Box

If the **Validate repository connection** option is selected, the URL connection is validated before being added to the **Repositories** view.

Edit Repository Location (Ctrl + Alt + E (Command + Alt + E on OS X))

Context-dependent action that allows you to edit the selected repository location using the **Edit SVN Repository** dialog box. It is active only when a repository location root is selected.

Change the Revision to Browse (Ctrl + Alt + B (Command + Alt + B on OS X))

Context-dependent action that allows you to change the selected repository revision using the **Change the Revision to Browse** dialog box. It is active only when a repository location root is selected.

Remove Repository Location (Ctrl + Alt + R (Command + Alt + R on OS X))

Allows you to remove the selected repository location from the view. It shows you a confirmation dialog box before removal. It is active only when a repository location root is selected.

Refresh (F5)

Refreshes the resource selected in the **Repositories** view.

Check out (Ctrl + Alt + O (Command + Alt + O on OS X))

Allows you to create a working copy from a repository directory, on your local file system. To read more about this operation, see the section *Check out a working copy*.

Export

Opens *the **Export** dialog box* that allows you to configure options for exporting a folder from the repository to the local file system.

Import:

Import folder (Ctrl + Shift + L (Command + Shift + L on OS X))

Allows you to import the contents of a specified folder from the file system into the selected folder in a repository. To read more about this operation, see the section *Importing resources into a repository*.

Note: The difference between the **Import folder** and **Share project** actions is that the latter also converts the selected directory into a working copy.

Import Files (Ctrl + Shift + I (Command + Shift + I on OS X))

Imports the files selected from the files system into the selected folder in the repository.

Working Copy Menu

(on OS X) Working Copies Manager

Opens a dialog box with a list of working copies that the Apache Subversion™ client is aware of. In this dialog box you can add existing working copies or remove those that are no longer needed.

Switch to

Selects one of the following view modes: **All Files**, **Modified**, **Incoming**, **Outgoing**, or **Conflicts**.

Refresh (F5)

Refreshes the state of the selected resources or of the entire working copy (if there is no selection).

Synchronize (Ctrl (Command on OS X) + Shift + S)

Connects to the repository and determines the working copy and repository changes made to the selected resources. The application switches to **Modified** view mode if the ***Always switch to 'Modified' mode*** *option* is selected.

Update (Ctrl (Command on OS X) + U)

Updates all the selected resources that have incoming changes to the HEAD revision. If one of the selected resources is a directory then the update for that resource will be recursive.

Update to revision/depth

Allows you to update the selected resources from the working copy to an earlier revision from the repository. You can also select the update *depth* for the current folder. You can find out more about the *depth* term in the *sparse checkouts* section.

Commit

Collects the outgoing changes from the selected resources in the working copy and allows you to choose exactly what resources to commit. A directory will always be committed recursively. Unversioned resources will be deselected by default. In the **Commit** dialog box you can also enter a comment before sending your changes to the repository.

Update all(Ctrl (Command on OS X) + Shift + U)

Updates all resources from the working copy that have incoming changes. It performs a recursive update on the synchronized resources.

Commit all

Commits all the resources with outgoing changes. It is disabled when **Incoming** mode is selected or the synchronization result does not contain resources with outgoing changes. It performs a recursive commit on the synchronized resources.

Revert (Ctrl (Command on OS X) + Shift + V)

Undoes all local changes for the selected resources. It does not contact the repository and the files are obtained from Apache Subversion™ pristine copy. It is available only for modified resources. See *Revert your changes* for more information.

Edit conflict (Ctrl (Command on OS X) + E)

Opens the **Compare** editor, allowing you to modify the content of the currently conflicting resources. For more information about editing conflicts, see *Edit conflicts*.

Mark Resolved (Ctrl (Command on OS X) + Shift + R)

Instructs the Subversion system that you resolved a conflicting resource. For more information, see *Merge conflicts*.

Mark as Merged (Ctrl (Command on OS X) + Shift + M)

Instructs the Subversion system that you resolved the pseudo-conflict by merging the changes and you want to commit the resource. Read the *Merge conflicts* section for more information about how you can solve the pseudo-conflicts.

Override and Update

Drops any outgoing change and replaces the local resource with the HEAD revision. This action is available on resources with outgoing changes, including conflicting ones. See the *Revert your changes* section.

Override and Commit

Drops any incoming changes and sends your local version of the resource to the repository. This action is available on conflicting resources. For more information see *Drop incoming modifications*.

Mark as copied

You can use this action to mark an item from the working copy as a copy of an other item under *version control*, when the copy operation was performed outside of an SVN client. The **Mark as copied** action is available when you select two items (both the new item and source item), and it depends on the state of the source item.

Mark as moved

You can use this action to mark an item from the working copy as being moved from another location of the working copy, when the move operation was performed outside of an SVN client. The **Mark as moved** action is available when you select two items from different locations (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Mark as renamed

You can use this action to mark an item from the working copy as being renamed outside of an SVN client. The **Mark as renamed** action is available when you select two items from the same directory (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Add to "svn:ignore" (Ctrl (Command on OS X) + Alt + I)

Allows you to add files that should not participate in the *version control* operations inside your working copy . This action can only be performed on resources not under *version control*. It actually modifies the value of the `svn:ignore` property in the parent directory of the resource. Read more about this in the *Ignore Resources Not Under Version Control* section.

Add to version control (Ctrl (Command on OS X) + Alt + V)

Allows you to add resources that are not under *version control*. For further details, see *Add Resources to Version Control* section.

Remove from version control

Schedules selected items for deletion from repository upon the next commit. The items are not removed from the file system after committing.

Clean up (Ctrl (Command on OS X) + Shift + C)

Performs a maintenance cleanup operation on the selected resources from the working copy. This operation removes the Subversion maintenance locks that were left behind. This is useful when you already know where the problem originated and want to fix it as quickly as possible. It is only active for resources under *version control*.

Expand All (Ctrl (Command on OS X) + Alt + X)

Displays all descendants of the selected folder. The same behavior is obtained by double-clicking a collapsed folder.

Collapse all (Ctrl (Command on OS X) + Alt + Z)

Collapses all descendants of the selected folder. The same behavior is obtained by double-clicking a expanded folder.

Compare Menu

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Last Change (Ctrl + E (Command + E on OS X))

Jumps to the last change.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Show Word Level Details

Provides a word-level comparison of the selected change.

Show Character Level Details

Provides a character-level comparison of the selected change.

Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on OS X))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

Note: When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces.

History Menu

Show History(Ctrl (Command on OS X) + H)

Displays the history for a SVN resource at a given revision. The resource can be one selected from the **Repositories** view, **Working Copy** view, or from the **Affected Paths** table from the **History** view, depending on which view was last focused when this action was invoked.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on OS X))

Opens the **Show Annotation** dialog box that computes *the annotations for a file and displays them in the **Annotations** view*, along with the history of the file in the **History** view.

Repositories

This operation is available for any resource selected from view, **Working Copy** view, **History** view or **Directory Change Sets** view, depending on which view was last focused when this action was invoked.

Revision Graph (Ctrl (Command on OS X) + G)

This action allows you to see the graphical representation of a resource's history. For more details about a resource's revision graph see the section *Revision Graph*. This operation is available for any resource selected in the **Repositories** view or **Working Copy** view.

Tools Menu

Share project

Allows you to *share a new project* using an SVN repository. The local project is automatically converted into an SVN working copy.

Branch / Tag

Allows you to copy the selected resource from the **Repositories** view or **Working Copy** view to a branch or tag into the repository. To read more about this operation, see the section *Creating a Branch / Tag*.

Merge (Ctrl (Command on OS X) + J)

Allows you to merge the changes made on one branch back into the trunk, or vice versa, using the selected resource from the working copy. To read more about this operation, see the section *Merging*.

Switch (Ctrl (Command on OS X) + Alt + W)

Allows you to change the repository location of a working copy, or only of a versioned item of the working copy, within the same repository. It is available when the selected item of the working copy is a versioned resource, except for *external* items. To read more about this action, see the *Switching the Repository Location* section.

Relocate

Allows you to change the base URL of the root folder of the working copy to a new URL when the base URL of the repository changed. For example, if the repository itself was moved to a different server. This operation is only available for the root item of the working copy. To read more about this operation, see the *Relocate a Working Copy* section.

Create patch (Ctrl (Command on OS X) + Alt + P)

Allows you to create a file containing all the differences between two resources, based on the `svn diff` command. To read more about creating patches, see *the section about patches*.

Working copy format

This submenu contains the following two operations:

Upgrade

Upgrades the format of the currently loaded working copy to the newest one known by Syncro SVN Client. This allows you to benefit of all the new features of the client.

Downgrade

Downgrades the format of the currently loaded working copy to SVN 1.7 format. This is useful if you want to use older SVN clients with the current working copy, or, by mistake, you have upgraded the format of an older working copy to SVN 1.8.

Note: SVN 1.7 working copies cannot be downgraded to older formats.

See the section *Working Copy Format* to read more about this subject.

Options Menu

Preferences

Opens the **Preferences** dialog box.

Menu Shortcut Keys

Opens the ***Menu Shortcut Keys*** *preferences page*, where users can configure in one place the keyboard shortcuts available for menu items available in Syncro SVN Client.

Global Run-Time Configuration

Allows you to configure SVN general options, that should be used by all the SVN clients you may use:

- **Edit 'config' file** - In this file you can configure various SVN client-side behaviors.
- **Edit 'servers' file** - In this file you can configure various server-specific protocol parameters, including HTTP proxy information and HTTP timeout settings.

Export Options

Allows you to export the current options to an XML file.

Import Options

Allows you to import options you have previously exported.

Reset Options

Resets all your options to the default ones.

Reset Authentication

Resets the Subversion authentication information.

Window Menu

Show View

Allows you to select the view you want to bring to front.

Show Toolbar

Allows you to select the toolbar you want to be visible.

Enable flexible layout

Toggles between a fixed and a flexible layout. When the flexible layout is enabled, you can move and dock the internal views to adapt the application to various viewing conditions and personal requirements.

Reset Layout

Resets all the views to their default position.

Help Menu

Help (F1)

Opens the **Help** dialog box.

Use online help (selected by default)

If this option is selected, when you select **Help** or press **F1** while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Show Dynamic Help view

Displays the **Dynamic Help** view.

Report Problem

Opens a dialog box that allows you to write the description of a problem that was encountered while using the application.

Support Center

Opens the Support Center web page in a browser.

About

Opens the **About** dialog box.

SVN Main Toolbar

The toolbar of the Syncro SVN Client SVN Repositories window contains the following actions:

 **Check out**

Checks out a working copy from a repository. The repository URL and the working copy format must be specified.

 **Synchronize**

Synchronizes the current working copy with the repository.

 **Update All**

Updates all resources of the working copy that have an older revision that repository.

 **Commit All**

Commits all resources of working copy that have a newer version compared to that of the repository.

Refresh

Refreshes the whole content of the current working copy from disk starting from the root folder. At the end of the operation, the modified files and folders that were not committed to repository yet, are displayed in the **Working Copy** view.

Compare

The selected resource is compared with:

- The *BASE* revision, when the selected resource is:
  - Locally modified and the **All Files** view mode is currently selected (no matter if there are incoming changes).
  - Locally modified and there are no incoming changes when any other view mode is selected.
- The remote version of the same resource, when remote information is available after a **Synchronize** operation (only when one of **Modified**, **Incoming**, **Outgoing** and **Conflicts** view modes is selected).
- The working copy revision, when the selected resource is from the **History** view.

Show History

Displays the history of the selected resource (from the **Working Copy** or **Repository** views) in the **History** view.

Show Annotation

Displays the annotations of the selected resource. The selected resource can be in the **Working Copy** or the **History** views.

Revision Graph

Displays the revision graph of the selected resource. The selected resource can be in the **Working Copy** or the **Repositories** views.

Enable/Disable flexible layout

Toggles between a fixed and a flexible layout. When the flexible layout is enabled, you can move and dock the internal views to adapt the application to various viewing conditions and personal requirements.

Status Bar

The status bar of the Syncro SVN Client window displays important details of the current status of the application. This information is available only in the **Working Copy** view.

Figure 789: Status bar

The status bar is composed of the following areas:

- The path of the currently processed file from the current working copy (during an operation such as **Check out** or **Synchronize**) or the result of the last operation.
- The current status of the following working copy options:
  - Show ignored files ( ).
  - Show deleted files ( ).
  - Process `svn:externals` definitions ( ).

  The options for ignored and deleted files are switched on and off from *the **Settings** menu* of the **Working Copy** panel:
- The format of the currently loaded working copy.

- The current numbers of incoming changes ( ), outgoing changes ( ) and conflicting changes ( ).
- A progress bar for the currently running SVN operation and a button ( ) that allows you to stop it.

Getting Started

This section explains the basic operations that can be done in Syncro SVN Client.

SVN Repository Location

This section explains how to add and edit the repository locations in Syncro SVN Client.

Add / Edit / Remove Repository Locations

Usually, team members do all of their work separately, in their own working copy, and then must share their work by committing their changes. This is done using an Apache Subversion™ repository. Oxygen XML Editor supports versions 1.4, 1.5, 1.6, 1.7, and 1.8 of the SVN repository format.

Before you can begin working with a Subversion repository, you must define a repository location in the ***Repositories*** *view*.

To create a repository location, use the **New Repository Location** action that is available in the **Repository** menu, the **Repositories** view toolbar, and in the contextual menu. This action opens the **New Repository Location** dialog box, which prompts you for the *URL of the repository* you want to connect to. You can also *use peg revisions at the end of the URLs* (for example, `URL@rev1234`) to browse only that specific revision. No authentication information is requested at the time the location is defined. It is left to the Subversion client to request the user and password information when it is needed. The main benefit of allowing Subversion to manage your password is that it prompts you for a new password only when your password changes.

Once you enter the repository URL, Oxygen XML Editor tries to contact the server to get the content of the repository for displaying it in the ***Repositories*** *view*. If the server does not respond in the timeout interval set in the preferences, an error is displayed. If you do not want to wait until the timeout expires, you can use the **Stop** button from the toolbar of the view.

To edit a repository location, use the **Edit Repository Location** action that is available in the **Repository** menu and in the contextual menu. This action opens the **Edit Repository Location** dialog box, which prompts you for the *URL of the repository* you want to connect to. You can also *use peg revisions at the end of the URLs* (for example, `URL@rev1234`) to browse only that specific revision.

To remove a repository location, use the **Remove Repository Location** action that is available in the **Repository** menu and in the contextual menu. A confirmation dialog box is displayed to make sure that you do not accidentally remove the wrong locations.

The order of the repositories can be changed in the **Repositories** view at any time with the **Up** arrow and **Down** arrow buttons on the toolbar of the view. For example, pressing the up arrow once moves the selected repository in the list up one position.

To set the reference revision number of an SVN repository use the **Change the Revision to Browse** action that is available in the **Repository** menu and in the contextual menu. The revision number of the repository is used for displaying the contents of the repository when it is viewed in the ***Repositories*** *view*. Only the files and folders that were present in the repository at the moment when this revision number was generated in the repository are displayed as contents of the repository tree. Also, this revision number is used for all the operations executed directly from the ***Repositories*** *view*.

Authentication

Five protocols are supported: *HTTP*, *HTTPS*, *SVN*, *SVN + SSH* and *FILE*. If the repository that you are trying to access is password protected, the **Enter authentication data** dialog box requests a user name and a password. If the **Store authentication data** checkbox is selected, the credentials are stored in Apache Subversion™ default directory:

- Windows - `%HOME%\Application Data\Subversion\auth`. Example: `C:\Documents and Settings\John\Application Data\Subversion\auth`
- Linux and OS X - `$HOME/.subversion/auth`. Example: `/home/John/.subversion/auth`

There is one file for each server that you access. If you want to make Subversion forget your credentials, you can use the **Reset authentication** command from the **Options** menu. This causes Subversion to forget all your credentials. When you reset the authentication data, restart Oxygen XML Editor for the change to take effect.

Tip: The *FILE* protocol is recommended if the SVN repository and Oxygen XML Editor are located on the same computer as it ensures faster access to the SVN repository compared with other protocols.

For HTTPS connections where client authentication is required by your SSL server, you must choose the certificate file and enter the corresponding certificate password that is used to protect your certificate.

When using a secure HTTP (HTTPS) protocol for accessing a repository, a **Certificate Information** dialog box is displayed and asks you whether you want to accept the certificate permanently, temporarily, or simply deny it.

If the repository has SVN+SSH protocol, the SSH authentication can also be made with a private key and a pass phrase.

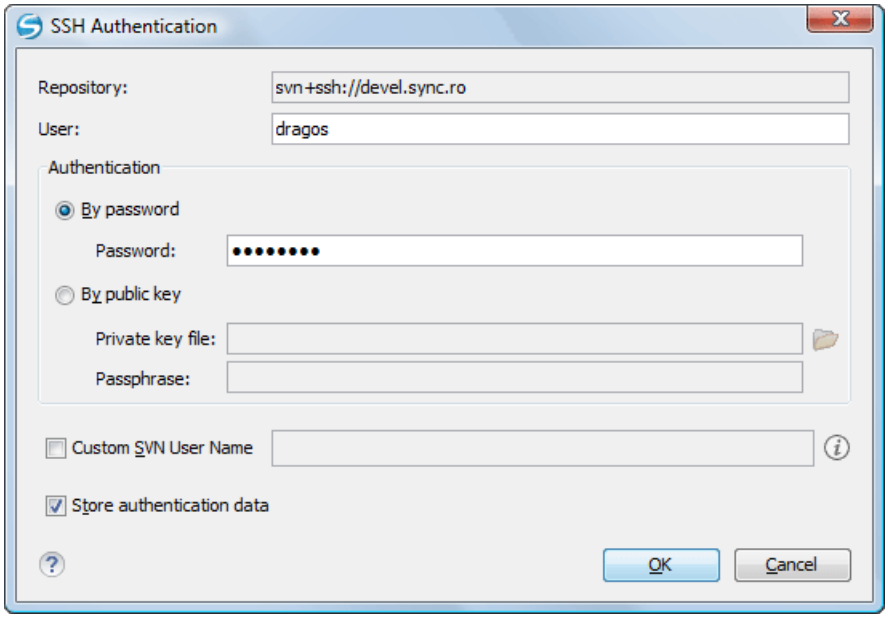

Figure 790: SSH Authentication Dialog Box

After the SSH authentication dialog box, another dialog box appears for entering the SVN user name that accesses the SVN repository. The SVN user name is recorded as the *committer* in SVN operations.

When connecting for the first time to a Subversion repository through SVN+SSH protocol, you will be asked to confirm if you trust the SSH host. The same dialog box is also displayed when the server changed the SSH key or when the key was deleted from the local Subversion cache folder.

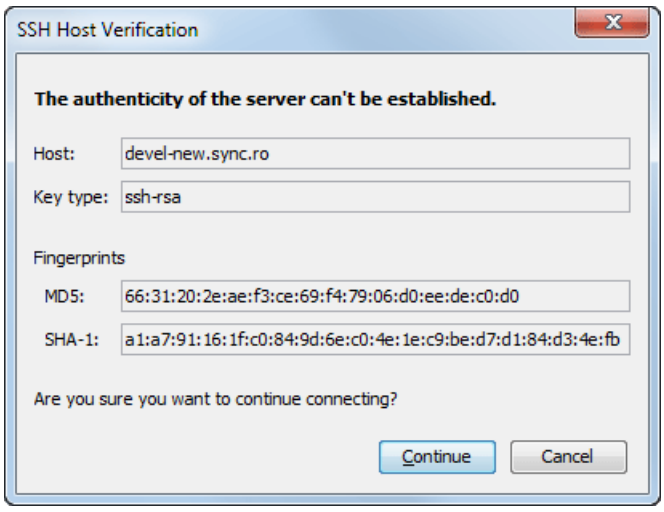

Figure 791: SSH server name and key fingerprint

Share a Project

Even if you start developing a new project, or you want to migrate an existing one to Subversion, the Syncro SVN Client allows you to easily share it with the rest of your team. The shared project directory is automatically converted to a working copy and added under Syncro SVN Client management. The **Share project** action is available in the **Tools** menu and the contextual menu of the **Repositories** view.

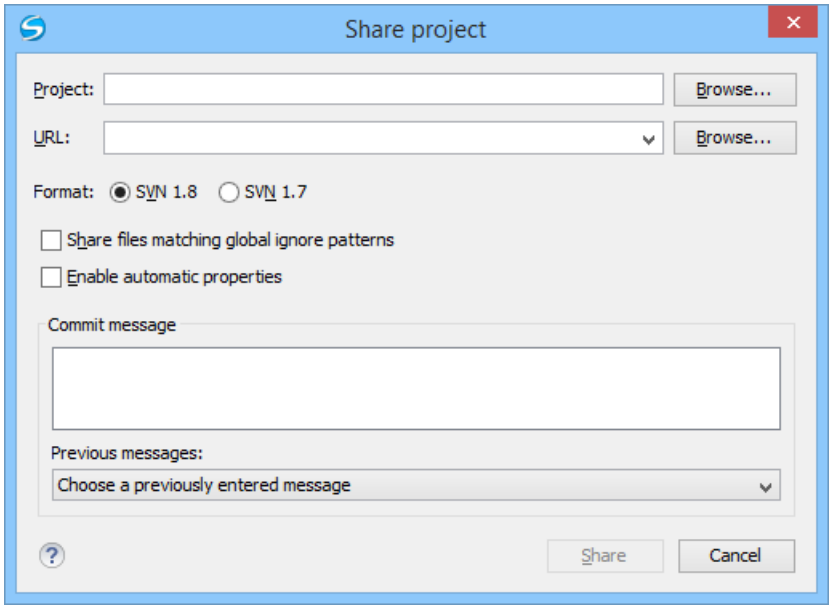

Figure 792: Share Project Dialog Box

The following options can be configured in the **Share project** dialog box:

Project

The location of the project folder on the local disk by using the text box or the **Browse** button. This folder should not be empty or already under version control.

Important: By default, the SVN system only imports the content of the specified folder, and not the root folder itself. Therefore, it is recommended to use the **Browse** button to select the project folder so that the client will automatically append the name of it to the specified URL.

URL

The new location of the project (inside the repository) that will be used to access it.

Note: *Peg revisions* have no effect for this operation since it is used to send information to the repository.

Attention: If the new location already exists, make sure that it is an empty directory to avoid mixing your project content with other files (if items exist with the same name, an error will occur and the operation will not proceed). Otherwise, if the address does not exist, it is created automatically.

Format

The SVN format of the working copy. You can choose between **SVN 1.8** or **SVN 1.7**.

Share files matching global ignore patterns

When selected, the file names that match the patterns defined in either of the following locations are also imported into the repository:

- The `global-ignores` property in *the SVN configuration file*.
- The ***File name ignore patterns*** *option* in the ***SVN*** *>* ***Working Copy*** *preferences page*.

Enable automatic properties/Disable automatic properties

Enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in *the SVN configuration file*.

Note: This option is available only when there are defined properties to be applied automatically for newly added items under version control. You can define these properties in the SVN `config` file (in the `auto-`

`props` section). Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.

Defining a Working Copy

An Apache Subversion™ working copy is an ordinary directory tree on your local system, containing a collection of files. You can edit these files however you want, your working copy being your private work area. To make your own changes available to others or incorporate changes made by others, you must explicitly tell Subversion to do so. You can even have multiple working copies of the same project.

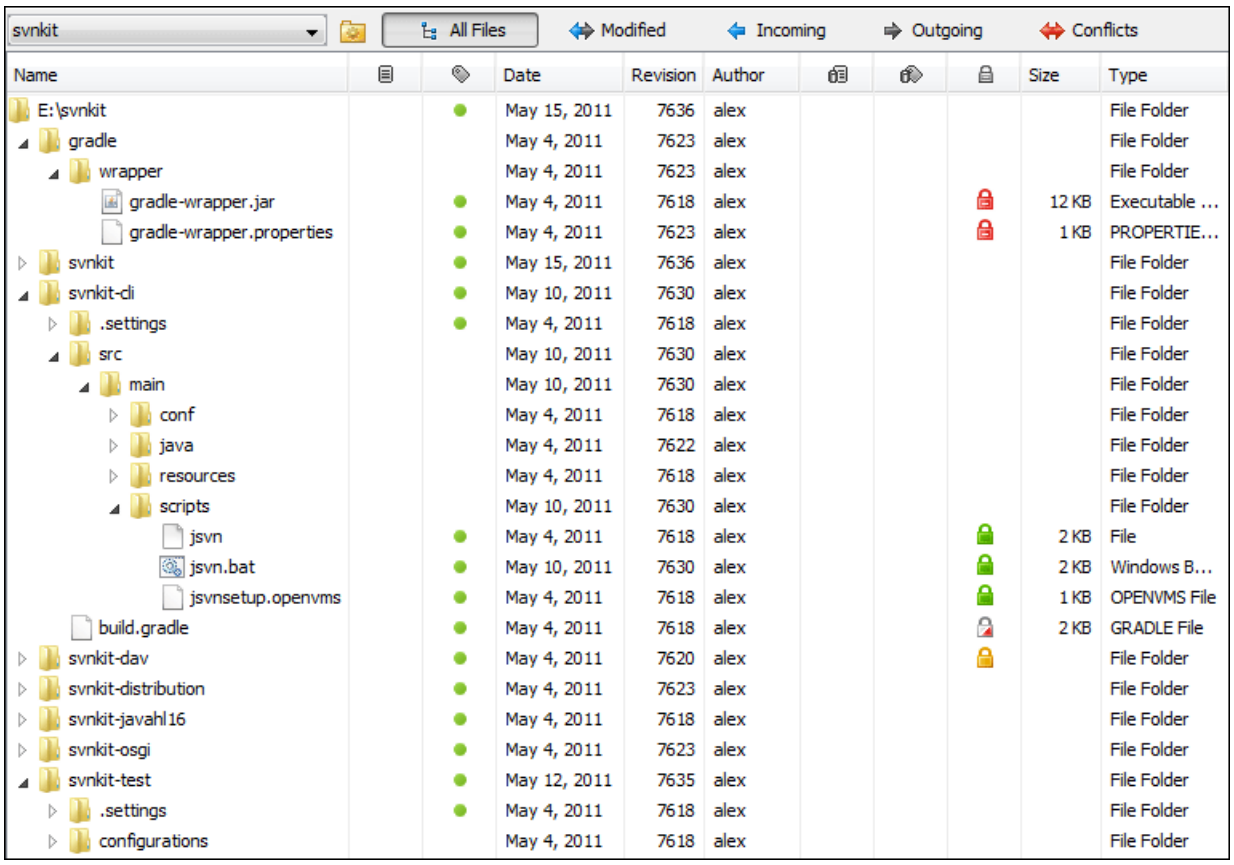

Figure 793: Working Copy View

A Subversion working copy also contains some extra files, created and maintained by Subversion, to help it keep track of your files. In particular, each directory in your working copy contains a subdirectory named `.svn`, also known as the working copy *administrative directory*. This administrative directory contains an unaltered copy of the last updated files from the repository. This copy is usually referred to as the *pristine copy* or the *BASE revision* of the working copy. These files help Subversion recognize which files contain unpublished changes, and which files are out-of-date with respect to others' work.

A typical Subversion repository often holds the files (or source code) for several projects. Usually each project is a subdirectory in the repository's file system tree. In this arrangement, a user's working copy usually corresponds to a particular sub-tree of the repository.

Check Out a Working Copy

Check out means to make a copy of a project from a repository to your local file system. This copy is called a *working copy*. An Apache Subversion™ working copy is a specially formatted directory structure that contains additional `.svn` directories that store Subversion information, as well as a pristine copy of each item that is checked out.

To check out a working copy, locate and select the desired directory in the **Repositories** view and select the **Check out** action from the contextual menu, the toolbar, or the **Repository** menu.

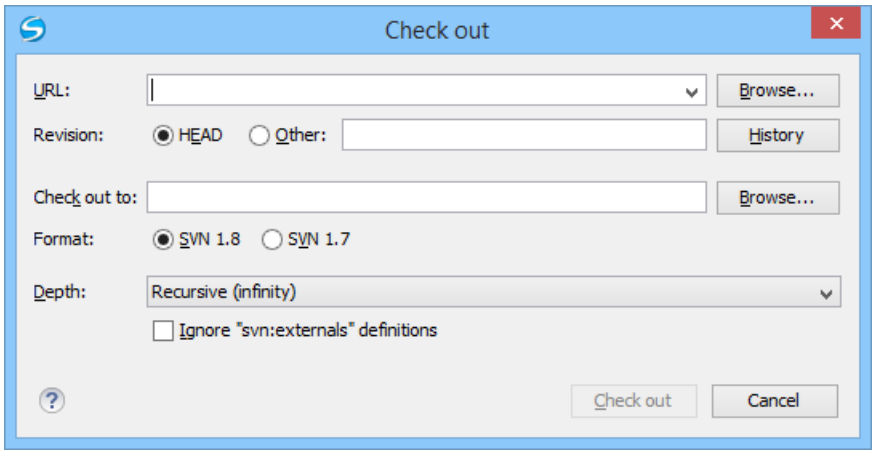

Figure 794: Check Out Dialog Box

The following options can be configured in the **Check out** dialog box:

URL

The location of the repository directory to be *checked out*.

Note: To check out an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg revision* at the end (for example, `URL@rev1234`).

Revision

You can choose between the **HEAD** or **Other** revision. If you need to *check out* a specific revision, specify it in the **Other** text box or use the **History** button and choose a revision from *the **History** dialog box*.

Check out to

Specify *the location where you want to check out* the new working copy by typing the local path in the text box or by using the **Browse** button. If the specified local path does not point to an existing directory, it will automatically be created.

Important: By default, the SVN system only checks out the content of the directory specified by the URL, and not the directory itself. Therefore, it is recommended to use the **Browse** button to select the *check out* location so that the client will automatically append the name of the remote directory to the path of the selected directory.

Warning: The destination directory should be empty. If files exist, they are skipped (left unchanged) by the *check out* operation and *displayed as modified* after the operation has finished. Also, the destination directory must not already be under version control.

Format

The SVN format of the working copy. You can choose between **SVN 1.8** or **SVN 1.7**.

Depth

The depth is useful if you want to *check out* only a part of the selected repository directory and bring the rest of the files and subdirectories in a future update. You can find out more about the checkout depth in the *sparse checkouts* section. You can choose between the following depths:

- **Recursive (infinity)** - Checks out all the files and folders contained in the selected folder.
- **Immediate children (immediates)** - Checks out only the child files and folders without recursing subfolders.
- **File children only (files)** - Checks out only the child files.
- **This folder only (empty)** - Checks out only the selected folder (no child file or folder is included).

Ignore "svn:externals" definitions

When selected, external items are ignored in the *check out* operation. This option is only available if you choose the **Recursive (infinity)** depth.

After a check out, the new working copy is added to the list in the ***Working Copy** view* and loaded automatically.

History Dialog Box

The **History** dialog box presents a list of revisions for a resource. It is opened from the dialog boxes that require setting an SVN revision number, such as *the **Check Out** dialog box* or *the **Branch / Tag** dialog box*. It presents information about revision, commit date, author, and commit comment.

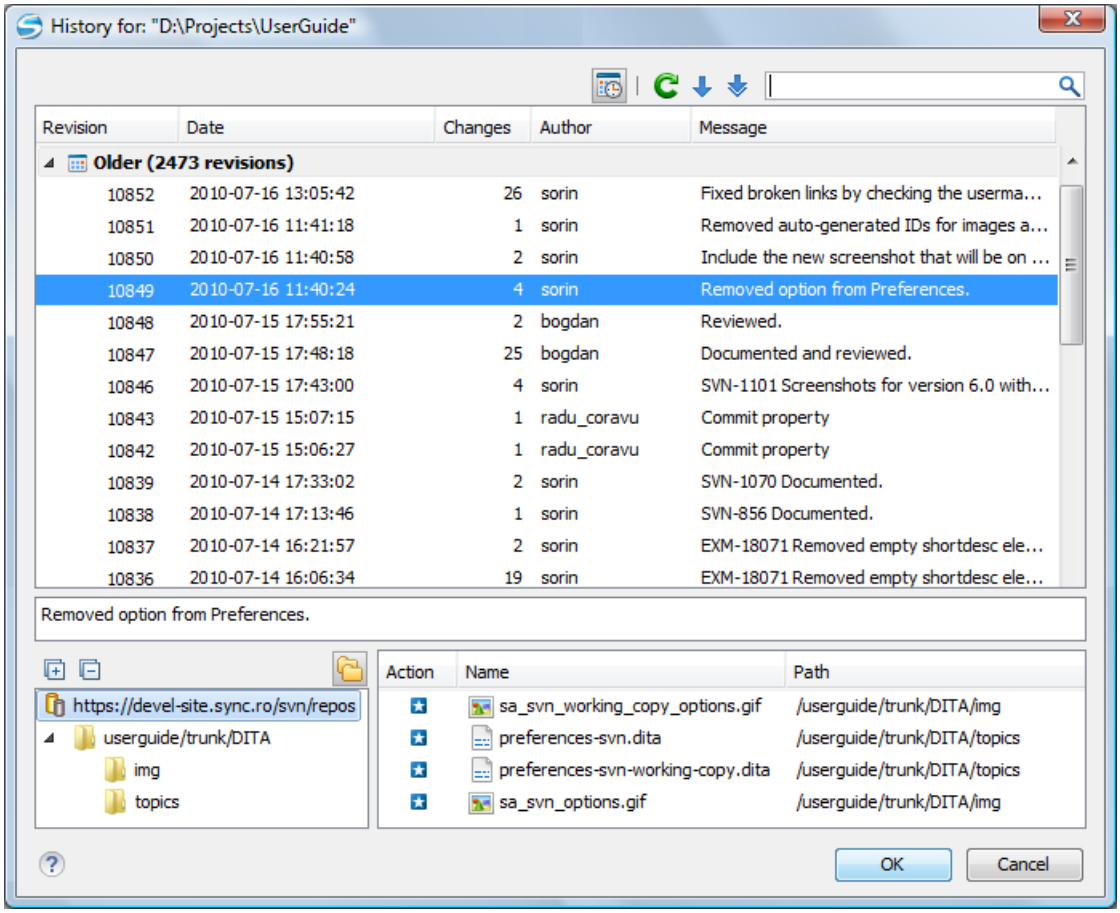

Figure 795: History Dialog Box

The initial number of entries in the list is 50. Additional revisions can be added to the list using the **Get next 50** and **Get all** buttons. The list of revisions can be refreshed at any time with the **Refresh** button. You can group revisions in predefined time frames (today, yesterday, this week, this month), by pressing the **Group by date** button from the toolbar.

The **Affected Paths** area displays all paths affected by the commit of the revision selected in history. You can see the changes between the selected revision and the file's previous state using the **Compare with previous version** action, available in the contextual menu.

Use an Existing Working Copy

Using an existing working copy is the process of taking a working copy that exists on your file system and connecting it to Apache Subversion™ repository. If you have a brand new project that you want to import into your repository, then see the section *Import resources into the repository*. The following procedure assumes that you have an existing valid working copy on your file system.

1. Click the **Working Copies Manager** toolbar button (on Mac OS X) in the ***Working Copy** view*.

   This action opens the **Working copies list** dialog box.
2. Press the **Add** button.
3. Select the working folder copy from the file system. The name is useful to differentiate between working copies located in folders with the same name. The default name is the name of the root folder of the working copy.

Note: For SVN 1.7 and newer working copies, all the internal information is kept only in the root directory. Thus, Syncro SVN Client needs to load the whole working copy.

4. Press the **OK** button.

The selected working copy is loaded and presented in the ***Working Copy*** *view*.

Notice: You can add working copies older than SVN 1.7. However, to load any of them, Syncro SVN Client will require to upgrade the working copy to SVN 1.8 format.

Manage Working Copy Resources

This section explains how to work with the resources that are displayed in the **Working Copy** view.

Edit Files

You can edit files from the ***Working Copy*** *view* by double clicking them or by right clicking them and choosing **Open** from the contextual menu.

Note that only one file can be edited at a time. If you try to open another file, it is opened in the same editor window. The editor has syntax highlighting for known file types, meaning that a different color is used for each type of recognized token in the file. If the selected file is an image, then it is previewed in the editor, with no access to modifying it.

After modifying and saving a file from a working copy, a modified marker - an asterisk (*) - will be added to the file's icon in the ***Working Copy*** *view*. The asterisk marks the files that have local modifications that were not committed to the repository.

Add Resources to Version Control

To share new files and folders (created in your working copy), add them to version control using the **Add to version control** option from the ***Working Copy*** *view*.

You can easily spot resources not under version control by the (*unversioned*) icon displayed in the **Local file status** column. Resources scheduled for addition (*added*) are displayed with this icon in the **Working Copy** view and are added in the repository after you commit them.

Note: Do not make a confusion between and icons. The former icon stands for resources that are actually copies of resources already committed in the repository, meaning they are *scheduled for addition with history*.

When you use the **Add to version control** option on a directory, its entire structure is scanned and all the resources that can be added under version control are presented.

Although it is not mandatory to add resources under version control explicitly, it is recommended. If you forgot to add a resource, when you *commit your changes*, the resource is presented in the commit dialog box, but not selected. When you commit and *unversioned* resource, it is automatically added under version control before starting the commit operation.

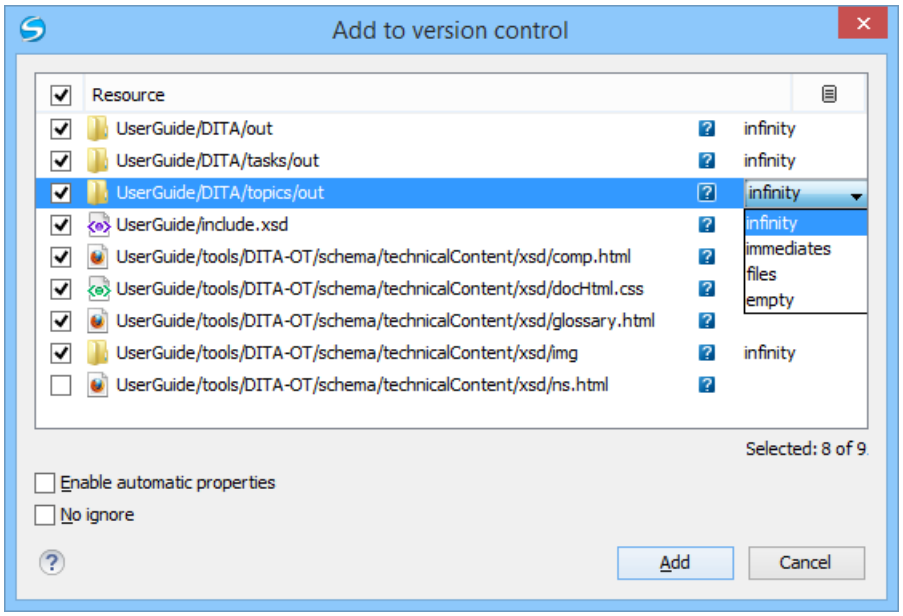

Figure 796: Add to Version Control Dialog Box

Note: *Ignored* (!) items can also be added under version control.

The **Depth** column is displayed only when directories are also presented in the dialog box. For any directory, you can use one of the available values to instruct Subversion to limit the scope of the operation to a particular tree depth.

Note: The initial value of the **Depth** field can have the following values, depending on the *listing mode of the items in the working copy view*:

- *infinity* - When the working copy items are presented as a tree.
- *files* - When the working copy items are presented compressed.
- *empty* - When the working copy items are presented flat.

When you add unversioned or ignored directories, the initial value of the **Depth** field also depends on the state of the **Show unversioned directories content** and **Show ignored directories content** options. If these options are selected, the value is based on the listing mode of the items in the working copy view. When they are not selected, the value is *empty* .

The following options are available in this dialog box:

- **Enable automatic properties** or **Disable automatic properties** - enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in the `config` file of the Subversion configuration directory.

  Note: This option is available only when there are defined properties to be applied automatically for resources newly added under version control. You can define these properties in the `config` file of the Subversion configuration directory, in the `auto-props` section. Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.
- **No ignore** - when you select this option, file-name patterns defined to ignore *unversioned* resources do not apply. Resources that are located inside an *unversioned* directory selected for addition, and match these patterns, are also scheduled for addition in the repository.

  Note: This option is available only when directories are also presented in the dialog box.

  You can define file-name patterns to ignore *unversioned* resources in one of the following locations:

  - In the `config` file of the Subversion configuration directory (the `global-ignores` option from the `miscellany` section).
  - In the Oxygen XML Editor options (*open the **Preferences** dialog box **(Options > Preferences)*** and go to **SVN** > **Working copy** > **Application global ignores**).

Each of the above two options is activated only when you select an item for which the option can be applied.

Ignore Resources Not Under Version Control

Some resources inside your working copy do not need to be subject to version control. These resources can be files created by the compiler, `*.obj`, `*.class`, `*.lst`, or output folders used to store temporary files. Whenever you *commit changes*, Apache Subversion™ shows your modified files in the commit dialog box, but the unversioned files are also listed. Since the unversioned files are committed unless otherwise specified, it is difficult to see exactly what you are committing.

The best way to avoid these problems is to add the derived files to the Subversion ignore list. That way they are never displayed in the commit dialog box and only genuine unversioned files that must be committed are displayed.

You can choose to ignore a resource by using the **Add to svn:ignore** action in the contextual menu of the ***Working Copy** view*.

In the **Add to svn:ignore** dialog box, you can specify the resource to be ignored by name or by a custom pattern. The custom pattern can contain the following wildcard characters:

- * - Matches any string of characters of any size, including the empty string.
- ? - Matches any single character.

For example, you can choose to ignore all text documents by using the pattern: `*.txt`.

The action **Add to svn:ignore** adds a predefined Subversion property called `svn:ignore` to the parent directory of the specified resource. In this property, there are specified all the child resources of that directory that must be ignored. The result is visible in the **Working Copy** view. The ignored resources are represented with gray icons.

Delete Resources

The **Delete** action is available in the contextual menu of the ***Working Copy** view*. When you delete an item from the working copy, it is marked as *deleted* (scheduled for deletion from repository upon the next commit) and removed from the file system. Depending on the state of each item, you are prompted to confirm the operation.

If a resource is deleted from the file system without Subversion's knowledge, the resource is marked as *missing* ( ) in your working copy. You can decide what you want to do with a *missing* item:

- In the case of a commit, any *missing* item is first automatically deleted and then committed.

  Note: Not any *missing* item can be committed as *deleted*, and removed from the repository. For example, you cannot commit an item that no longer exists on the disk and that was scheduled for addition ( ) previously, since this item does not exist in the repository, but you can use the **Delete** action instead.
- If you want to recover *missing* items, either *update* the items themselves or one of their parent directories. This fetches their latest version from the repository.

You can also delete conflicting items (file content conflicts, property conflicts, tree-conflicts) and Syncro SVN Client automatically marks them as resolved.

Note: It is recommended that you resolve conflicts manually to avoid loosing any important remote modifications.

Finally, you can change your mind and *revert* the deleted items to their initial, pristine, state.

Copy Resources

You can copy resources from various locations of the working copy. You select them in the ***Working Copy** view* and then use **Copy to** from the contextual menu. This is not a simple file system copy, but an Apache Subversion™ command. It will copy the resource and the copy will also have the original history. This is one of the important features of Subversion, as you can keep track of where the copied resources originated.

Based on the selected items, the **Copy to** action is available only if it can be performed. Even if the operation would not normally be possible in SVN (due to some invalid local file states against copy), Oxygen XML Editor performs the copy operation as a simple file system operation. This means no SVN versioning meta-data is affected.

Note:

- If you copy an item to a directory that is *not under version control* (*unversioned* or *ignored*), the history of the item is not preserved. For example, when copying directories, all items inside them will also be copied without history.
- If you copy a directory that contains *external* items, these are not copied. This is specific for SVN 1.7 working copies only. To fetch the *external* items, use the **Update** operation on the copied directory.

In the **Copy to** dialog box, you can navigate through the working copy directories to choose a target directory, to copy inside it. If you try to copy a single resource you are also able to change that resource's name. For *versioned* items, you can select **Ignore resource history** to copy them without their history (similar to a simple file system copy).

Note: The **Copy to** dialog box only presents all the local directories that are a valid destination against the copy operation, based on their local file status. Also, the *working copy settings* are taken into account.

In the **Commit** dialog box, only the directory in question will appear without its children.

Move Resources

As in the case of the copy command, you can move several resources at once. Select the resources in the ***Working Copy*** *view* and choose the **Move to** action from the contextual menu. The move command actually behaves as if a copy followed by a delete command were issued. You will find the moved resources at the desired destination and also at their original location, but marked as *deleted*.

Note: *External* items cannot be moved using the **Move to** action, because they cannot be deleted. Instead, you should edit the `svn:externals` property defining the *external* item and use the **Update** operation on the item's parent folder for the change to take effect.

Attention: For SVN 1.8 working copies: when committing items that were moved and/or renamed, make sure you select both the source and the destination. Otherwise, the commit operation will fail.

Rename Resources

The **Rename** action is available in the contextual menu of the ***Working Copy*** *view* and can be performed on a single resource. This action acts as a move command with the destination directory being the same as the original location of the resource. A copy of the original item is created with the new name, also keeping its history. The original item is marked as *deleted*.

Note: *External* items cannot be renamed using the **Rename** action because they cannot be deleted. Instead, you should edit the *svn:externals* property defining the *external* item, then use the **Update** operation on the item's parent folder for the change to take effect.

Attention: For SVN 1.8 working copies: when committing items that were moved and/or renamed, make sure you select both the source and the destination. Otherwise, the commit operation will fail.

Lock / Unlock Resources

The idea of version control is based on the *copy-modify-merge* model of file sharing. This model states that each user contacts the repository and creates a local working copy (check out). Users can then work independently and modify their working copies according to their needs. When their goal has been accomplished, it is time for the users to share their work with the others, to send them to the repository (commit). When a user has modified a file that has been also modified on the repository, the two files will have to be merged. The version control system assists the user with the merging as much as it can, but in the end the user is the one that must make sure it is done correctly.

The copy-modify-merge model only works when files are contextually mergeable: this is usually the case of line-based text files (such as source code). However this is not always possible with binary formats, such as images or sounds. In these situations, the users must each have exclusive access to the file, ending up with a *lock-modify-unlock* model. Without this, one or more users could end up wasting time on changes that cannot be merged.

An SVN lock is a piece of metadata that grants exclusive access to a user. This user is called the lock owner. A lock is uniquely identified by a lock token (a string of characters). If someone else attempts to commit the file (or delete a parent of the file), the repository demands two pieces of information:

- User authentication - the user performing the commit must be the lock owner

- Software authorization - the user's working copy must have the same lock token as the one from the repository, proving that it is the same working copy where the lock originated from.

Scanning for Locks

When starting to work on a file that is not contextually mergeable (usually a binary file), it is better to verify if someone else is not already working on that file. You can do this in the ***Working Copy** view* by selecting one or more resources, then right-clicking them and choosing the **Scan for Locks** action from the contextual menu.

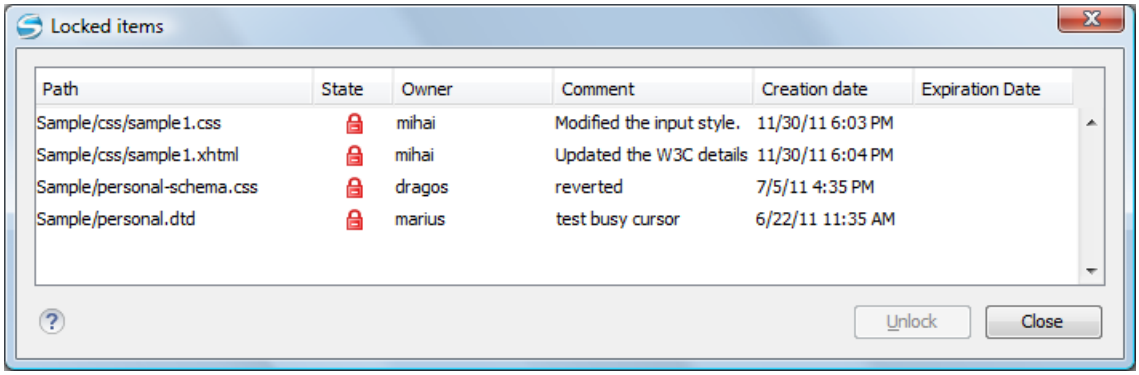

Figure 797: Locked Items Dialog Box

The **Locked items** dialog box contains a table with all the resources that were found locked on the repository. For each resource there are specified: resource path, state of the lock, owner of the lock, lock comment, creation and expiration date for the lock (if any).

The state of the lock can be one of the following:

- - Appears when one of the following conditions apply:
  - Another user has locked the file in the repository.
  - The file was locked by the same user from another working copy.
  - The file was locked from the **Repositories** view.
- - Displayed after you have locked a file from the current working copy.
- - A file already locked from your working copy is no longer locked in the repository (it was unlocked by another user).
- - A file already locked from your working copy is being locked by another user. Now the owner of the file lock is the user who stole the lock from you.

You can unlock a resource by selecting it and pressing the **Unlock** button.

Working Copy Locks on page 1738

Repository Locks on page 1731

Locking a File

By locking a file, you have exclusive write access to it in the repository.

You can lock a file from your working copy or directly from the **Repositories** view.

Note: You can only lock files (not directories). This is a restriction imposed by Apache Subversion™.

The **Lock** dialog box allows you to write a comment when you set a lock or when you *steal* an existing one. Note that you should *steal* a lock only after you made sure that the previous owner no longer needs it. Otherwise, you may cause an unsolvable conflict, which could be the reason the lock was put there in the first place. The Subversion server can have a policy concerning lock stealing, as it may not allow you to do this if certain conditions are not met.

The lock stays in place until you unlock the file or until someone breaks it. There is also the possibility that the lock expires after a period of time specified in the Subversion server policy.

Unlocking a File

A file can be unlocked from the contextual menu of the ***Working Copy*** *view*. A dialog box will prompt you to confirm the unlocking and it will also allow you to break the lock (unlock it by force).

Synchronize with Repository

In the work cycle you will need to incorporate other people's changes (update) and to make your own work available to others (commit). This is what the **Incoming** and **Outgoing** modes of *the* ***Working Copy*** *view* was designed for, to help you send and receive modifications from the repository.

The **Incoming** and **Outgoing** modes of this view focus on incoming and outgoing changes. The incoming changes are the changes that other users have committed in the repository since you last updated your working copy. The outgoing changes are the modifications you made to your working copy as a result of editing, removing or adding resources.

The view presents the status of the working copy resources against the BASE revision after a **Refresh** operation. You can view the state of the resources versus a repository HEAD revision by using the **Synchronize** action from *the* ***Working Copy*** *view*.

View Differences

One of the most common requirements in project development is to see what changes have been made to the files from your Working Copy or to the files from the repository. You can examine these changes after a synchronize operation with the repository, by using the **Open in compare editor** action from the contextual menu.

The text files are compared using a built-in ***Compare*** *view* that uses a line differencing algorithm or a specified external diff application (if such an application is set in the ***SVN Diff*** *preferences page*). When a file with outgoing status is involved, the compare is performed between the file from the working copy and the BASE revision of the file. When a file with incoming or conflict status is involved, the differences are computed using a three-way algorithm that means that the local file and the repository file are each compared with the BASE revision of the file. The results are displayed in the same view. The differences obtained from the local file comparison are considered outgoing changes and the ones obtained from the repository file comparison are considered incoming changes. If any of the incoming changes overlap outgoing changes then they are in conflict.

A special case of difference is a *diff pseudo-conflict*. This is the case when the left and the right sections are identical but the BASE revision does not contain the changes in that section. By default, this type of changes are ignored. If you want to change this, you can go to the **SVN** preferences page and select the ***Allow unversioned obstructions*** *option*.

The right editor of the internal compare view presents either the BASE revision or a revision from the repository of the file so its content cannot be modified. By default, when opening a synchronized file in the **Compare** view, a compare is automatically performed. After modifying and saving the content of the local file presented in the left editor, another compare is performed. You will also see the new refreshed status in the ***Working Copy*** *view*.

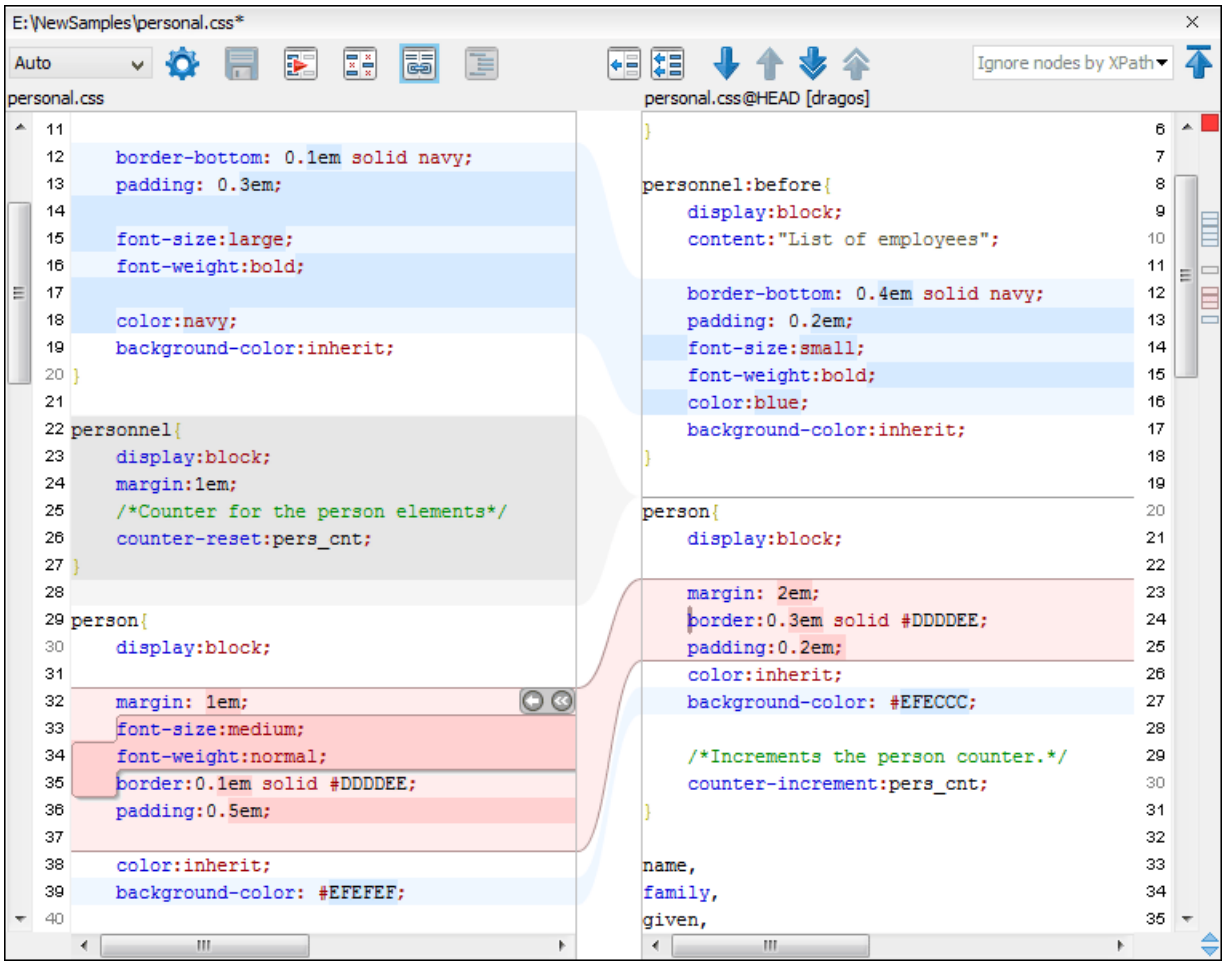

Figure 798: Compare View

At the top of each of the two editors, there are presented the name of the opened file, the corresponding SVN revision number (for remote resources) and the author who committed the associated revision.

There are three types of differences:

- Incoming changes - Changes committed by other users and not present yet in your working copy file. They are marked with a blue highlight and on the middle divider the arrows point from right to left.
- Outgoing changes - Changes you have done in the content of the working copy file. They are marked with a gray highlight and the arrows on the divider are pointing from left to right.
- Conflicting changes - This is the case when the same section of text that you already modified in the local file has been modified and committed by some other person. They are marked with a red highlight and red diamonds on the divider.

There are numerous actions and options available in the ***Compare View*** *toolbar* or in the **Compare** menu from the main menu. You can decide that some changes need adjusting or that new ones must be made. After you perform the adjustments, you may want to perform a new compare between the files. For this case there is an action called **Perform files differencing**. After each files differencing operation the first found change will be selected. You can navigate from one change to another by using the actions **Go to first**, **Go to previous**, **Go to next** and **Go to last modification**. If you decide that some incoming change needs to be present in your working file you can use the action **Copy change from right to left**. This is useful also when you want to override the outgoing modifications contained in a conflicting section. The **Copy all non-conflicting changes from right to left** action copies all incoming changes that are not contained inside a conflicting section in your local file.

Suppose that only a few words or letters are changed. Considering that the differences are performed taking whole lines of text into account, the change will contain all the lines involved. To find exactly what words or letters have changed, the **Word Details** and **Character Details** dialog boxes are available. They present a more detailed comparison result when you double-click the middle divider of a difference.

When you want to examine only the changes in the real text content of the files, while disregarding the changes in the number of white spaces between words or lines, there is an option available in the *SVN Preferences* that allows you to enable or disable the white space ignoring feature of the compare algorithm.

Conflicts

A file conflict occurs when two or more developers have changed the same few lines of a file or the properties of the same file. As Subversion knows nothing of your project, it leaves resolving the conflicts to the developers. Whenever a conflict is reported, you should open the file in question, and try to analyze and resolve the conflicting situation.

Real Conflicts vs Mergeable Conflicts

There are two types of conflicts:

- *real conflict* (icon in *Name* column) - Syncro SVN Client considers the following resource states to be real conflicts:
  - *conflicted* state - A file reported by SVN as being in this state is obtained after it was updated/merged while having incoming and outgoing content or property changes at the same time, changes that could not be merged. A content conflict (icon in *Local file status* column) is reported when the modified file has binary content or it is a text file and both local and remote changes were found on the same line. A properties conflict (icon in *Local properties status* column) is reported when a property's value was modified both locally and remotely.
  - *tree conflicted* state (icon in *Local file status* column) - Obtained after an update or merge operation, while having changes at the directory structure level (for example, file is locally modified and remotely deleted or locally scheduled for deletion and remotely modified).
  - *obstructed* state (icon in *Local file status* column) - Obtained after a resource was versioned as one kind of object (file, directory, symbolic link), but has been replaced outside Syncro SVN Client by a different kind of object.
- *pseudo-conflict* (icon in *Name* column) - A file is considered to be in *pseudo-conflict* when it contains both incoming and outgoing changes. When incoming and outgoing changes do not intersect, an update operation may automatically merge the incoming file content into the existing locally one. In this case, the *pseudo-conflict* marker is removed. This marker is used only as a warning that should prevent you to run into a real conflict.

Note:

- A conflicting resource cannot be committed to repository. You have to resolve it first, by using **Mark Resolved** action (after manually editing/merging file contents) or by using **Mark as Merged** action (for pseudo-conflicts).
- and icons are presented only when one of the following view modes is selected: **Modified**, **Incoming**, **Outgoing**, **Conflicts**.
- The icon is used also for folders to signal that they contain a file in real conflict or pseudo-conflict state.

Content Conflicts vs Property Conflicts

A *Content conflict* appears in the content of a file. A merge occurs for every inbound change to a file that is also modified in the working copy. In some cases, if the local change and the incoming change intersect each other, Apache Subversion™ cannot merge these changes without intervention. So if the conflict is real when updating the file in question the conflicting area is marked like this:

```
<<<<<<< filename
your changes
=======
code merged from repository
>>>>>>> revision
```

Also, for every conflicted file Subversion places three additional temporary files in your directory:

- `filename.ext.mine` - This is your file as it existed in your working copy before you updated your working copy, that is without conflict markers. This file has your latest changes in it and nothing else.
- `filename.ext.rOLDREV` - This is the file that was the BASE revision before you updated your working copy, that is the file revision that you updated before you made your latest edits.
- `filename.ext.rNEWREV` - This is the file that Subversion client just received from the server when you updated your working copy. This file corresponds to the HEAD revision of the repository.

OLDREV and NEWREV are revision numbers. If you have conflicts with binary files, Subversion does not attempt to merge the files by itself. The local file remains unchanged (exactly as you last changed it) and you will get `filename.ext.r*` files also.

A *Property conflict* is obtained when two people modify the same property of the same file or folder. When updating such a resource a file named `filename.ext.prej` is created in your working copy containing the nature of the conflict. Your local file property that is in conflict will not be changed. After resolving the conflict, you should use the **Mark resolved** action to commit the file. Note that the **Mark resolved** action does not really resolve the conflict. It just removes the conflicted flag of the file and deletes the temporary files.

Edit Real Content Conflicts

The conflicts of a file in the conflicted state (a file with the red double arrow icon) can be edited visually with the **Compare** view (the built-in file comparison tool) or with an *external diff application*. Resolving the conflict means deciding for each conflict if the local version of the change will remain or the remote one instead of the special conflict markers inserted in the file by the SVN server.

The **Compare** view (or the external diff application *set in Preferences*) is opened with the **Edit Conflict** action, which is available on the contextual menus of *the **Working Copy** view* for files in the conflicted state (an update operation was executed but the differences could not be merged without conflicts). The external diff application is called with 3 parameters because it is a 3-way diff operation between the local version of the file from the working copy and the HEAD version from the SVN repository with the BASE version from the working copy as common ancestor.

If the***Show warning dialog when edit conflicts*** *option* is selected, you will be warned at the beginning of the operation that the operation will overwrite the conflict version of the file received from the SVN server (the version that contains the conflict markers <<<<<<<, =======, >>>>>>>) with the original local version of the file that preceded the update operation. If you press the OK button the visual conflict editing will proceed and a backup file of the conflict version received from the SVN server is created in the same working copy folder as the file with the edited conflicts. The name of the backup file is obtained by appending the extension `.sync.bak` to the file as stored on the SVN server. If you press the **Cancel** button the visual editing will be aborted.

The usual actions on the differences between two versions of a file are available on the toolbar of this view:

 **Save**

Saves the modifications of the local version of the file displayed in the left side of the view.

 **Perform Files Differencing**

Looks for differences between the two files displayed in the left and right side panels.

 **Ignore Whitespaces**

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces.

 **Synchronized scrolling**

Toggles synchronized scrolling. When toggled on, a selected difference can be seen in both panels.

 **Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on OS X))**

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

Note: When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

 **Copy Change from Right to Left**

Copies the selected difference from the file in the right panel to the file in the left panel.

 **Copy All Changes from Right to Left**

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

The operation begins by overwriting the conflict version of the file received from the SVN server (the version that contains the conflict markers <<<<<<<, =======, >>>>>>>) with the original local version of the file before running the update action that created the conflict. After that the differences between this original local version and the repository version are displayed in the **Compare** view.

If you want to edit the conflict version of the file directly in a text editor instead of the visual editing offered by the **Compare** view you should work on the local working copy file after the update operation without running the action **Edit Conflict**. If you decide that you want to edit the conflict version directly after running the action **Edit Conflict** you have to work on the `.sync.bak` file.

If you did not finish editing the conflicts in a file at the first run of the action **Edit Conflict** you can run the action again and you will be prompted to choose between resuming the editing where the previous run left it and starting again from the conflict file received from the SVN server.

After the conflicts are edited and saved in the local version of the file you should run one of the following:

- The **Mark Resolved** action on the file so that the result of the conflict editing process can be committed to the SVN repository.
- The **Revert** action so that the repository version overwrites all the local modifications.

Both actions remove the backup file and other temporary files created with the conflict version of the local file.

Revert Your Changes

If you want to undo changes made in your working copy, since the last update, select the items you are interested in, right-click to display the contextual menu and select **Revert**. A dialog box will open that shows you the files and folders that you have changed and can be reverted. Select those you want to revert and click the **OK** button. Revert will undo only your local changes. It does not undo any changes that have already been committed. If you choose to revert a conflicting item to its pristine copy, then the eventual conflict is solved by losing your outgoing modifications. If you try to revert a resource not under version control, the resource will be deleted from the file system.

Note: By default, a directory will be recursively reverted (including any other modified item it contains). However, if the directory has only property changes, you need to explicitly choose if the operation will include any modified items found inside it.

If you want some of your outgoing changes to be overridden you must first open the file in ***Compare*** *view* and choose the sections to be replaced with ones from the repository file. This can be achieved either by editing directly the file or by using the action **Copy change from right to left** from the ***Compare*** *view toolbar*. After editing the conflicting file you have to run the action **Mark as merged** before committing it.

If you want to drop all local changes and bring all incoming changes into your working copy resource, you can use the **Override and update** action. It discards the changes in the local file and updates it from the repository. A dialog box will display the files that will be affected.

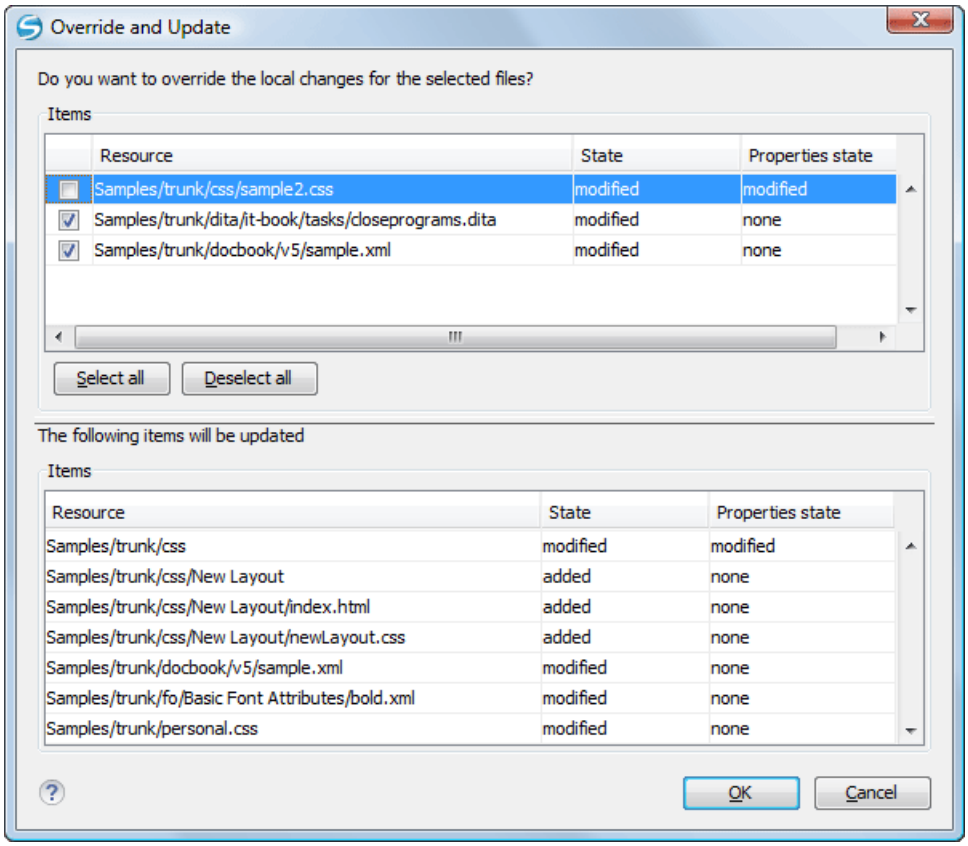

Figure 799: Override and Update Dialog Box

In the first table of the dialog box you will be able to see the resources that will be overridden. In the second table you will find the list of resources that will be updated. Only resources that have an incoming status are updated.

Tip: If you want to roll-back out of your working copy changes that have already been committed to the repository, see *Merge Revisions*.

Merge Conflicted Resources

Before you can safely commit your changes to the repository you must first resolve all conflicts. In the case of pseudo-conflicts they can be resolved in most cases with an update operation that will merge the incoming modifications into your working copy resource. In the case of real conflicts, conflicts that persist after an update operation, it is necessary to resolve the conflict using the built-in compare view and editor or, in the case of properties conflict, the ***Properties*** *view*. Before you can commit you must *mark as resolved* the affected files.

Both pseudo and real conflicts can be resolved without an update. You should open the file in the compare editor and decide which incoming changes need to be copied locally and which outgoing changes must be overridden or modified. After saving your local file you have to use the *Mark as merged* action from the contextual menu before committing.

Drop Incoming Modifications

In the situation when your file is in conflict but you decide that your working copy file and its content is the correct one, you can decide to drop some or all of the incoming changes and commit afterwards. The action **Mark as merged** proves to be useful in this case too. After opening the conflicting files with ***Compare*** *view*, *Editor* or editing their properties in the **Properties** view and deciding that your file can be committed in the repository replacing the existing one, you should use the **Mark as merged** action. When you want to override completely the remote file with the local file you should run the **Override and commit** action, which drops any remote changes and commits your file.

In general it is much safer to analyze all incoming and outgoing changes using the **Compare** view and only after to update and commit.

Tree Conflicts

A *tree conflict* is a conflict at the directory tree structure level and occurs when the user runs an update action on a resource that has the following conditions:

- It is locally modified and the same resource was deleted from the repository (or deleted as a result of being renamed or moved).
- It was locally deleted (or deleted as a result of being renamed or moved) and the same resource is incoming as modified from the repository.

The same conflict situation can occur after a merge or a switch action. The action ends with an error and the folder containing the file that is now in the tree conflict state is also marked with a conflict icon.

Such a conflict can be resolved in one of the following ways that are available when the user double clicks on the conflicting resource or when running the **Edit conflict** action:

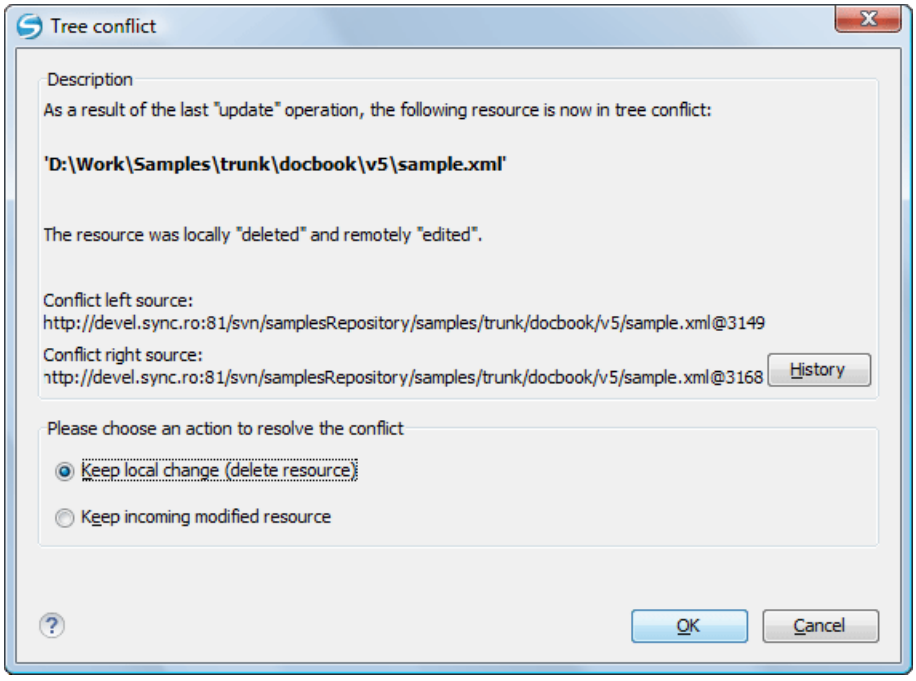

Figure 800: Resolve a tree conflict

- **Keep local change (delete resource)** - Keeps the incoming change that comes from the repository.
- **Keep incoming modified resource** - If there is a renamed version of the file committed by other user that will be added to the working copy too.

Update the Working Copy

While you are working on a project, other members of your team may be committing changes to the project repository. To get these changes, you have to *update* your working copy. Updating may be done on single files, a set of selected files, or recursively on entire directory hierarchies. The update operation can be performed from ***Working Copy*** *view*. It updates the selected resources to the last synchronized revision (if remote information is available) or to the *HEAD* revision of the repository.

There are three different kinds of incoming changes:

- *Non-conflicting* - A non-conflicting change occurs when a file has been changed remotely but has not been modified locally.
- *Conflicting, but auto-mergeable* - An auto-mergeable conflicting change occurs when a text file has been changed both remotely and locally (for example, has non-committed local changes) but the changes are on different lines of text. Not applicable to binary resources (for example, multimedia files, PDFs, executable program files)
- *Conflicting* - A conflicting change occurs when one or more of the same lines of a text file have been changed both remotely and locally.

If the resource contains only incoming changes or the outgoing changes do not intersect with incoming ones then the update will end normally and the Subversion system will merge incoming changes into the local file. In the case of a conflicting situation the update will have as result a file with conflict status.

The Oxygen XML Editor allows you to update your working copy files to a specific revision, not only the most recent one. This can be done by using the **Update to revision/depth** action from the **Working Copy** view (**All Files** view mode) or the **Update to revision** action from the ***History*** *view* contextual menu.

If you select multiple files and folders and then you perform an **Update** operation, all of those files and folders are updated one by one. The Subversion client makes sure that all files and folders belonging to the same repository are updated to the exact same revision, even if between those updates another commit occurred.

When the update fails with a message saying that there is already a local file with the same name Subversion tried to check out a newly versioned file, and found that an unversioned file with the same name already exists in your working folder. Subversion will never overwrite an unversioned file unless you specifically do this with an **Override and update** action. If you get this error message, the solution is simply to rename the local unversioned file. After completing the update, you can check to see if the renamed file is still needed.

Send Your Changes to the Repository

Sending the changes you made to your working copy is known as *committing* the changes. If your working copy is up-to-date and there are no conflicts, you are ready to commit your changes.

The **Commit** action sends the changes from your local working copy to the repository. The **Commit** dialog box presents all the items that you can commit.

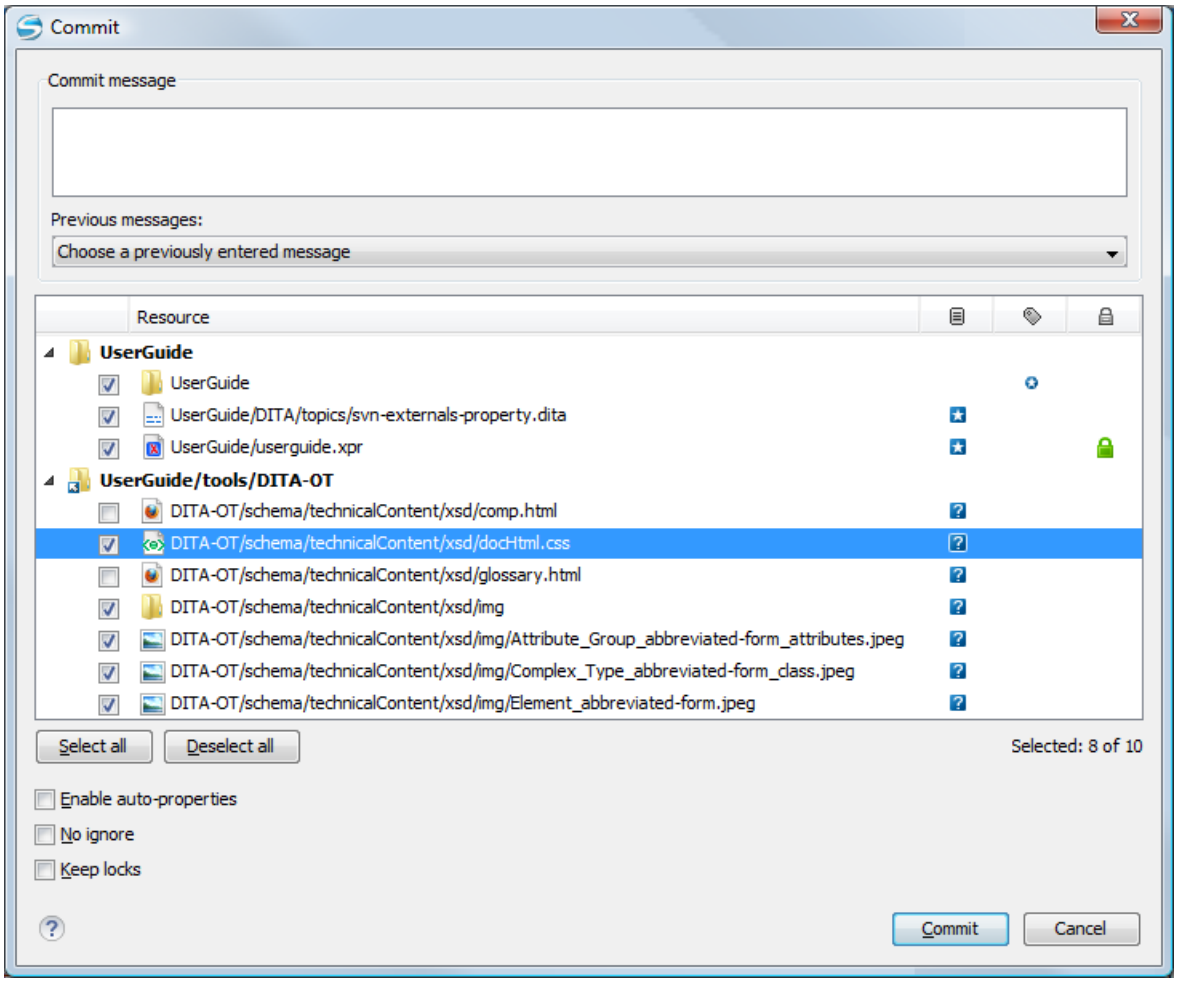

Figure 801: Commit dialog box

Enter a message to associate with the commit, or choose a previous message from the **Previous messages** list (the last 10 commit messages will be remembered even after restarting the SVN client application).

An item that can be committed has one of the following states: *added*, *modified* (content or properties), *replaced*, and *deleted*. All items that have one of these states are selected in the dialog box by default. If you do not want to commit one of the items, deselect it.

Attention: For SVN 1.8 working copies: when committing items that were moved and/or renamed, make sure you select both the source and the destination. Otherwise, the commit operation will fail.

Besides the items that have one of the mentioned states, Syncro SVN Client also includes the files being *unversioned* or *missing* and these items are handled automatically:

- *Unversioned* items are added under version control.
- *Missing* items are deleted.

Note: If the **Show unversioned directories content** option is not selected, the **Commit** dialog box does not display the items inside an *unversioned*directory.

Unversioned or *missing* items are not selected by default in the **Commit** dialog box, unless you have selected them explicitly when issuing the commit command.

Note: In some cases, items that have one of the above states are not presented in the **Commit** dialog box.

For example:

- Items that have been *added* or *replaced* previously, but now are presented as *missing* after being removed from the file system, outside of an SVN client. Such items do not exist in the repository and you should use the **Delete** action to remove them from your working copy.

- Items that have incoming changes from the repository, after a synchronization. You need to have your working copy up-to-date before committing your changes.
- Files that, after a synchronization, appear as locked by other users or from other locations than the current working copy.

Note: Due to dependencies between items, when you select or clear an *unversioned* ( ) or *added* ( ) item in the **Commit** dialog box, other items with one of these states can be selected or cleared automatically.

The modifications that will be committed for each file can be reviewed in the compare editor window by double clicking a file in the **Commit** dialog box, or by right clicking and selecting the **Show Modifications** action from the contextual menu. This option is available to review only file content changes, not property changes.

The **Local file status** column indicates the actual state of the items and the **Local properties status** column indicates whether or not the properties of an item are modified.

The **Lock information** column is displayed if at least one of the files in the **Commit** dialog box has lock information associated with it, valid against the commit operation.

The following options are available in this dialog box:

- **Enable automatic properties** or **Disable automatic properties** - enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in the `config` file of the Subversion configuration directory.

  Note: This option is available only when there are defined properties to be applied automatically for resources newly added under version control. You can define these properties in the `config` file of the Subversion configuration directory, in the `auto-props` section. Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.
- **Keep locks** - selecting the **Keep locks** option preserves any locks you set on various files.

  Note: This option is available only when files that you locked are presented in the dialog box.

Each of the above options is activated only when you select an item for which the option can be applied.

Your working copy must be up-to-date with respect to the resources you commit. This is ensured by using the **Update** action prior to committing, resolving conflicts and re-testing as needed. If your working copy resources you are trying to commit are out of date you will get an appropriate error message.

Committing to Multiple Locations

Although Subversion does not support committing to multiple locations at once, Syncro SVN Client offers this functionality regarding *external* items.

If items to be committed belong to different *external* definitions than those found in the working copy, they are grouped under the corresponding item that indicates their repository origin. Each parent item is rendered bold and its corresponding repository location is presented when hovering it. Parent items are decorated with a small arrow ( ) if they are *external* definitions. The working copy root directory is never decorated and is not presented if there are no *external* items listed (all items belong to the main working copy). Each child item is presented relative to the parent item.

Note: When an *external* directory has modifications of its own, it is presented both as a parent item and as an item that you can select and commit. This is always the case for *external* files.

The sets of items belonging to *external* definitions from the same repository are committed together, resulting a single revision. So, the number of revisions can be smaller than the number of *externals*. External definitions are considered from the same repository if they have the same protocol, server address, port, and repository address within the server.

Note: *External* files are always from the same repository as the parent directory that defines them, so they are always committed together with the changes from their parent directory.

Integration with Bug Tracking Tools

Users of bug tracking systems can associate the changes they make in the repository resources with a specific ID in their bug tracking system. The only requirement is that the user includes the bug ID in the commit message

that they enter in the **Commit** dialog box. The format and the location of the ID in the commit message are configured with SVN properties.

To make the integration possible Syncro SVN Client needs some data about the bug tracking tool used in the project. You can configure this using the following *SVN properties* that must be set on the folder that contains resources associated with the bug tracking system (usually they are set recursively on the root folder of the working copy):

- **bugtraq:message** - A string property. If it is set the ***Commit*** *dialog box* will display a text field for entering the bug ID. It must contain the string *%BUGID%*, which is replaced with the bug number on commit.
- **bugtraq:label** - A string property that sets the label for the text field configured with the **bugtraq:message** property.
- **bugtraq:url** - A string property that is the URL pointing to the bug tracking tool. The URL string should contain the substring *%BUGID%* which Syncro SVN Client replaces with the issue number. That way the resulting URL will point directly to the correct issue.
- **bugtraq:warnifnoissue** - A boolean property with the values *true*/*yes* or *false*/*no*. If set to *true*, the Syncro SVN Client will warn you if the bug ID text field is left empty. The warning will not block the commit, only give you a chance to enter an issue number.
- **bugtraq:number** - A boolean property with the value *true* or *false*. If this property is set to *false*, then any character can be entered in the bug ID text field. If the property is set to *true* or is missing then only numbers are allowed as the bug ID.
- **bugtraq:append** - A boolean property. If set to *false*, then the bug ID is inserted at the beginning of the commit message. If *yes* or not set, then it's appended to the commit message.
- **bugtraq:logregex** - This property contains one or two regular expressions, separated by a newline. If only one expression is set, then the bug ID's must be matched in the groups of the regular expression string (for example, `[Ii]ssue #?(\d+)`). If two expressions are set, then the first expression is used to find a string which relates to a bug ID but may contain more than just the bug ID (for example, `Issue #123` or `resolves issue 123`). The second expression is then used to extract the bug ID from the string extracted with the first expression. An example: if you want to catch every pattern `issue #XXX` and `issue #890, #789` inside a log message you could use the following strings:
  - `[Ii]ssue #?(\d+)(,? ?#?(\d+))+`
  - `(\d+)`

The data configured with these SVN properties is stored on the repository when a revision is committed. A bug tracking system or a statistics tools can retrieve the revisions that affected a bug from the SVN server and present the commits related to that bug to the user of the bug tracking system.

If the **bugtraq:url** property was filled in with the URL of the bug tracking system and this URL includes the *%BUGID%* substring as specified above in the description of the **bugtraq:url** property then the ***History*** *view* presents the bug ID as a hyperlink in the commit message. Clicking such a hyperlink in the commit message of a revision opens a Web browser at the page corresponding to the bug affected by that commit.

Obtain Information for a Resource

This section explains how to obtain information for a SVN resource:

Request Status Information for a Resource

While you are working with the SVN Client you often need to know which files you have changed, added, removed, or renamed, or even which files got changed and committed by others. This is where the **Synchronize** action from the ***Working Copy*** *view* comes in handy. The **Working Copy** view shows you every file that has changed your working copy, as well as any unversioned files you may have.

If you want more detailed information about a given resource, you can use the  **Show SVN Information** action. This action is available from the **File** menu or the contextual menu of the **Working Copy**, **Repositories**, **History**, or **Directory Change Set** views, or from the **Revision Graph** dialog box. The **SVN Information** dialog box will be displayed, showing information about the selected resource. The information displayed depends on the location of the item (local or remote) and may include the following:

- Local path and repository location
- Revision number

- Last change author, revision and date
- Information about locks
- Local file status
- Local properties status
- Local directory depth
- Repository location and revision number for copied files or directories
- Path information about locally moved items
- Path information about conflict generated files
- Remote file status
- Remote properties status
- File size and other information

The value of a property of the resource displayed in the dialog box can be copied by right-clicking the property and selecting the **Copy** action.

Request History for a Resource

In Apache Subversion™, both files and directories are versioned and have a history. If you want to examine the history for a selected resource and find out what happened at a certain revision you can use the **History view** that can be accessed from *Repositories view*, *Working Copy view*, *Revision Graph*, or *Directory Change Set view*. From the **Working copy view** you can display the history of local versioned resources. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Related Information:

History View on page 1744

Management of SVN Properties

In the ***Properties*** *view* you can read and set the Apache Subversion™ properties of a file or folder. There is a set of predefined properties with special meaning to Subversion. For more information about properties in Subversion see the SVN Subversion specification. Subversion properties are revision dependent. After you change, add or delete a property for a resource, you have to commit your changes to the repository.

If you want to change the properties of a given resource you need to select that resource from the ***Working Copy*** *view* and run the **Show properties** action from the contextual menu. The ***Properties*** *view* will show the local properties for the resource in the working copy. Once the Properties view is visible, it will always present the properties of the currently selected resource. There are actions available in the **Properties** view *toolbar* that allow you to add, change, and delete the properties.

If you choose the **Add a new property** action, a new dialog box will appear that contains the following:

- **Name** - Combo box that allows you to enter the name of the property. The drop-down menu of the combo box presents the predefined Subversion properties (such as **svn:ignore**, **svn:externals**, **svn:needs-lock**, etc.)
- **Current value** - Text area that allows you to enter the value of the new property.

If the selected item is a directory, you can also set the property recursively on its children by selecting the **Set property recursively** checkbox.

If you want to change the value for a previously set property, you can use the **Edit property** action, which will display a dialog box with the following information:

- **Name** - Property name (cannot be changed).
- **Current value** - The current value (can be changed).
- **Base value** - The value of the property, if any, from the resource in the pristine copy (cannot be changed).

If you want to completely remove a property previously set you can choose the **Remove property** action. It will display a confirmation dialog box in which you can also choose if the property will be removed recursively.

There is a **Refresh** action in the ***Properties*** *view* that can be used when the properties have been changed from outside the view. This can happen, for example, when the view was already presenting the properties of a resource and they have been changed after an **Update** operation.

Branches and Tags

One of the fundamental features of version control systems is the ability to create a new line of development from the main one. This new line of development will always share a common history with the main line if you look far enough back in time. This line is known as a *branch*. Branches are mostly used to try out features or fixes. When the feature or fix is finished, the branch can be merged back into the main branch (*trunk*).

Another feature of version control systems is the ability to take a snapshot of a particular revision, so you can at any time recreate a certain build or environment. This is known as *tagging*. Tagging is especially useful when making release versions.

In Apache Subversion™, there is no difference between a *tag* and a *branch*. On the repository, both are ordinary directories that are created by copying. The trick is that they are cheap copies instead of physical copies. Cheap copies are similar to hard links in Unix, which means that they merely link to a specific tree and revision without making a physical copy. As a result, branches and tags occupy little space on the repository and are created very quickly.

Provided that nobody ever commits to the directory in question, it remains a tag. If people start committing to it, it becomes a branch.

Create a Branch / Tag

To create a branch or tag by copying a directory, use the **Branch/Tag** action that is available in the **Tools** menu when an item is selected in the ***Working Copy*** *view* or ***Repositories*** *view*, or from the contextual menu of the **Repositories** view.

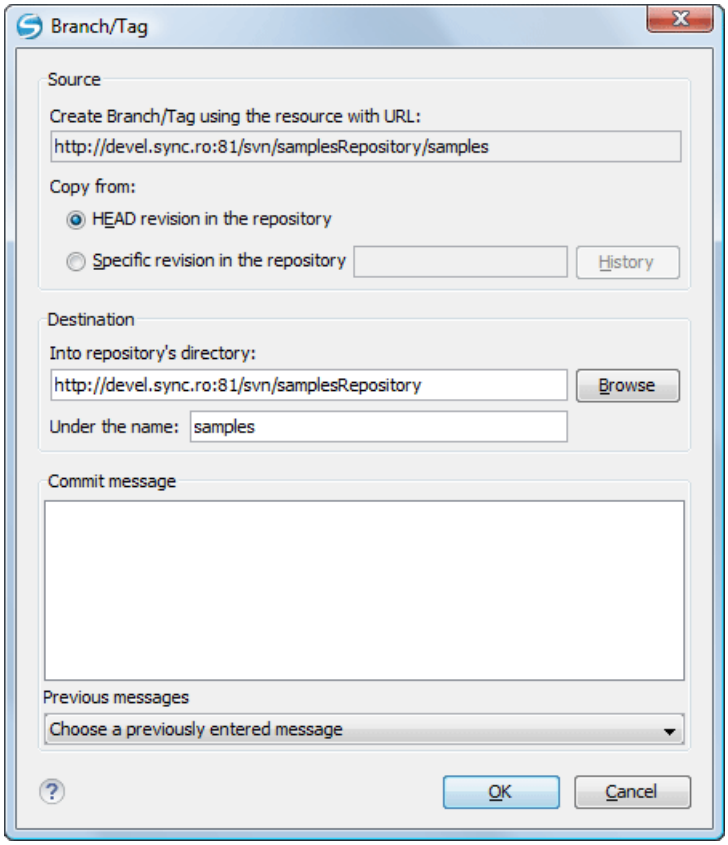

Figure 802: Branch/Tag Dialog Box

You can configure the following options in this dialog box:

You can specify the source revision of the copy in the **Copy from** section. You can choose between the following options:

- **HEAD revision in the repository** - The new branch or tag will be copied in the repository from the HEAD revision. The branch will be created very quickly, as the repository will make a *cheap* copy.

- **Specific revision in the repository** - The new branch will be copied into the repository, but you can specify the exact desired revision. For example, this is useful if you forgot to make a branch or tag when you released your application. If you click the **History** button you can select the revision number from *the **History** dialog box*. This type of branch will also be created very quickly.
- **Working copy** - (Available only if the item is selected from the **Working copy** view). The new branch will be a copy of your local working copy. If you have updated some files to an older revision in your working copy, or if you have made local changes, that is exactly what goes into the copy. This involves transferring some data from your working copy back to the repository, or more specifically, the locally modified files.

You can specify the location of the new branch or tag in the **Destination** section:

- **Into repository's directory** - *The URL of the parent directory* of the new branch or tag.

  Note: *Peg revisions* have no effect for this operation since it is used to send information to the repository.
- **Under the name** - You can specify another branch or tag name other than the name of the resource selected in the **Repositories** or **Working copy** view.

The new branch or tag will be created as a child of the specified URL of the repository directory and will have the new name.

Merging

At some stage during the development process, you will want to merge the changes made on a *branch* back into the *trunk*, or vice-versa. The *merge* is accomplished by comparing two points (branches or revisions) in the repository and applying the obtained differences to your working copy. This process is closely related to the *diff* concept.

Note: A *branch* is a line of development that exists independently of another line, yet still shares a common history if you look far enough back in time. A *branch* always begins life as *a copy of something* (such as a trunk, another branch, or tag), and moves on from there, generating its own history.

The **Merge** action is available in the **Tools** menu. The working copy item selected when you issued the command will be the one receiving the generated changes. If there is no item selected, the *merge* operation will be performed on the entire working copy.

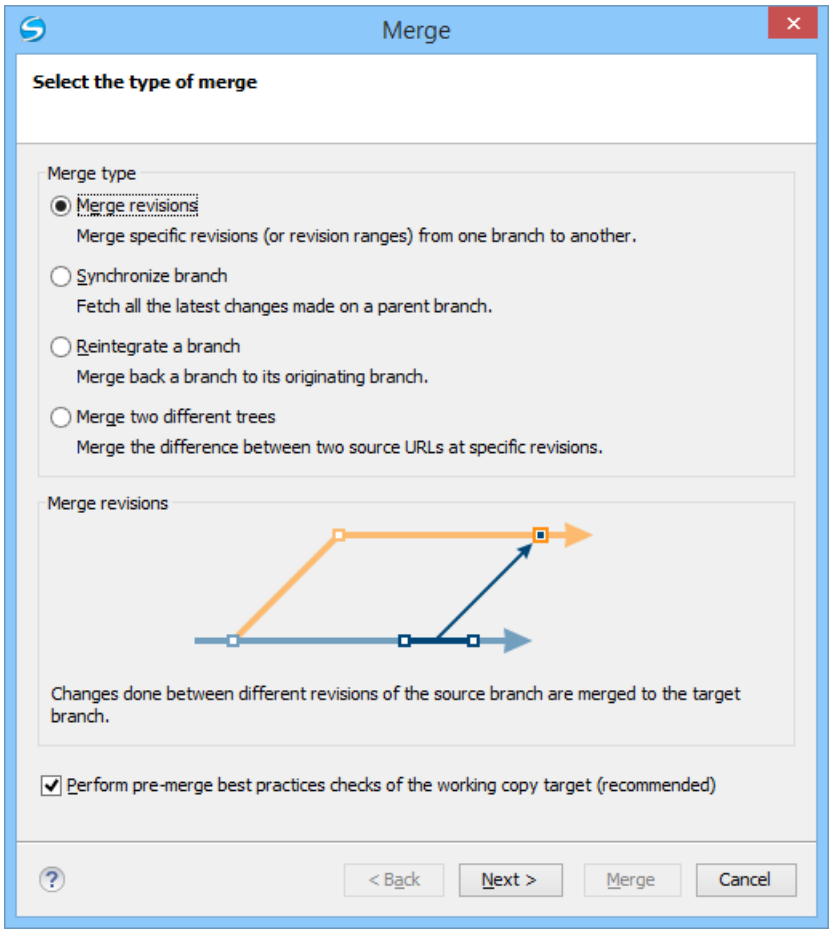

Figure 803: Merge Wizard

The four types of merging are as follows:

- ***Merge revisions*** - Port changes from one branch to another. Note that the *trunk* can also be considered a branch, in this context.
- ***Synchronize branch*** - Fetch all the changes made on a parent branch (or the *trunk*) to a child branch.
- ***Reintegrate a branch*** - Merge a branch back to its parent branch (can also be the *trunk*).
- ***Merge two different trees*** - Integrate the changes done on a branch to a different branch.

It is recommended that you enable the following pre-merge check:

- ***Perform pre-merge best practices checks of the working copy target*** - When selected, the SVN Client checks if the working copy target item is ready for the merge operation and displays the **pre-merge checks** wizard page.

Remember: It is a good idea to perform a merge into an unmodified working copy. If you have made changes to your working copy, commit them first. If the *merge* does not go as you expect, you may want to revert the changes and revert cannot recover your uncommitted modifications.

Important: The above recommendation becomes mandatory when *reintegrating a branch*.

Pre-Merge Checks

Before performing a merge, it is recommended to make sure that the working copy target item is ready for the merge operation. The SVN Client includes a best practices step that checks various conditions of the working copy target item to ensure that the merge operation will succeed. By selecting the **Perform pre-merge best practices checks of the working copy target** option in the first page of the **Merge** wizard, the **Pre-merge checks** wizard page is displayed to give you a summary of the verified conditions.

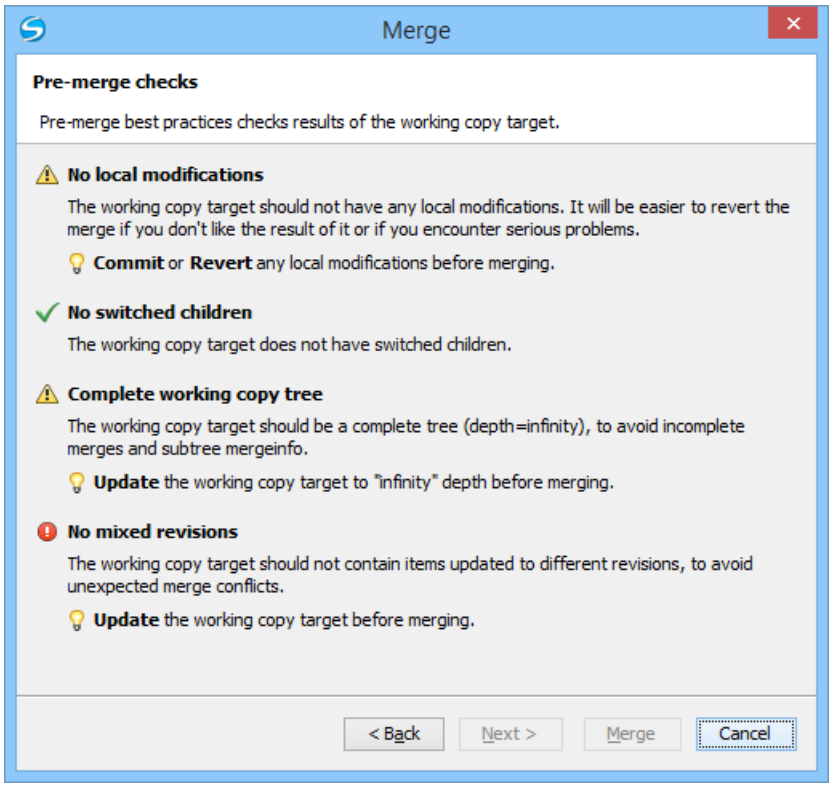

Figure 804: Pre-Merge Checks Wizard Page

The following conditions are checked in this operation:

No local modifications

The working copy item (or any of its children) receiving the merge should not contain uncommitted changes, to make it easier to revert merge-generated changes if you encounter unexpected results.

Tip: If this condition fails, you should *commit* or *revert* the local modifications before merging.

No switched children

None of the children of the working copy item receiving the merge should be switched, to avoid incomplete merges and *subtree mergeinfo*.

Tip: If this condition fails, you should switch back all the children before merging.

Complete working copy tree

The working copy item receiving the merge should be a complete directory tree structure with an infinite depth, to avoid incomplete merges and *subtree mergeinfo*.

Tip: If this condition fails, you should change the *sticky* depth of the working copy item receiving the merge to *infinity* value.

No mixed revisions

To avoid unexpected merge conflicts, the working copy item that is receiving the merge should not contain items that were updated to other revisions.

Tip: If this condition fails, you should *update* the working copy before merging.

Each condition is marked with an icon that represents the state of the condition. The possible states are as follows:

- (**Successful**) - The condition is fulfilled successfully.
- (**Warning**) - The condition is not fulfilled, but it is not mandatory.
- (**Error**) - The condition is not fulfilled and is mandatory (therefore, the operation cannot proceed until you solve the error).

Tip: For each condition state, a message is displayed that gives you additional information about the results and, for warning or errors, a hint that explains how you can solve them.

Important: After solving any of the warnings or errors, it is recommended that you perform the *pre-merge checks* again to make sure your new changes are valid.

Merge Revisions

This case is when you have made one or more changes to a branch and you want to duplicate them in another branch. For example, we know that a problem has been fixed by committing revisions 17, 20, and 25 on branch B1. These changes are also needed in branch B2. Thus, to merge them, we need a working copy of the B2 branch.

To merge revisions from a different branch, follow these steps:

1. Go to menu **Tools** > **Merge**.
   The **Merge** wizard is opened.
2. Select the **Merge revisions** option.
3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.
   a) Press the **Next** button.
   If the **Perform pre-merge best practices checks of the working copy target** option is selected, *the **Pre-Merge Checks** wizard page* is displayed.

   Note: If errors are found you need to solve them before proceeding.
4. Press the **Next** button.
   The **Merge revisions** wizard page is displayed.
5. In the **Merge from (URL)** text box, enter *the URL of the branch or tag* that contain the changes that you want to duplicate in your working copy. In our example, it is the URL of the B1 branch.

   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop down menu, which displays a history of previously used URLs.

   Note: If the URL belongs to a different repository than the working copy, the **Ignore ancestry / Disable merge tracking** option (in the ***Merge Options** wizard page*) will be selected automatically (and you cannot change this). This is because the *Subversion client cannot track changes between different repositories*.

   Tip: You can also specify a *peg revision* at the end of the URL (for example, `URL@rev1234`). The peg revision does not affect the merge range you select. By default, the `HEAD` revision is assumed.
6. In the **Revisions to merge** section, choose between the **all revisions** and **specific revision(s)** options.

   - **all revisions** - The operation will include *all eligible revisions* that were not yet merged.
   - **specific revision(s)** - You can specify one or more individual revisions and/or revision ranges. Also, you can mix *forward* ranges (for example, `1-5`), *backward* ranges (for example, `20-15`), and subtract specific revisions from a range (for example, `1-5, -3`).

   Note: If using the Subversion command-line client, a revision range of the form `1-5` means all changes starting from revision 2 up to revision 5 (the changes necessary to reach revision 5, committed after revision 1). Unlike the Subversion command-line client, in Syncro SVN Client the revision ranges are inclusive, meaning that it will process all revisions, starting with revision 1, up to and including revision 5.

   Attention: The `HEAD` revision is the only non-numerical revision allowed, and it can only be used when specifying revision ranges as one of the ends of the range (for example, `10-HEAD`). Be careful when using it, as it might not refer to the desired revision, if it has recently been committed by another user.

   Tip: If you want to perform a *reverse merge* and roll-back your working copy changes that have already been committed to the repository, use the *negative revisions* notation (for example, `-7`) or *backward revision ranges* (for example, `20-10`).

   a) If you press the **History** button, *the **History** dialog box* is displayed, which allows you to select one or more revisions to be merged.
7. Optionally, if you want to *configure the options* for your merge, press the **Next** button.
   The ***Merge Options** wizard page* is displayed that allows you to configure options for the operation.

Warning: If the **Ignore ancestry / Disable merge tracking** option is selected and you chose **all revisions** in the **Revisions to merge** section, revisions that were previously merged will also be included, which may result in conflicts.

8. Press the **Merge** button.
   The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, *you may need to resolve conflicts* after making major changes.

Note: The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Synchronize a Branch

While working on your own branch, other people on your team might continue to make important changes in the parent branch (which can be the *trunk* itself or any other branch). It is recommended to periodically duplicate those changes in your branch to make sure your changes are compatible with them. This is done by performing a *synchronize merge*, which will bring your branch up-to-date with any changes made to its ancestral parent branch since your branch was last created or synchronized. Subversion is aware of the history of your branch and can detect when it split away from the parent branch.

Frequently keeping your branch in sync with the parent branch helps you to prevent unexpected conflicts when the time comes for you to duplicate your changes back into the parent branch. The synchronization uses *merge tracking* to skip all those revisions that have already been merged, thus a sync merge can be repeated periodically to fetch all the latest changes of the parent branch to keep up-to-date with it.

Important: It is recommended to synchronize the whole working copy that was created from the child branch (the root of the working copy), rather than just a part of it.

After running the *synchronize merge*, your working copy from the child branch now contains new local modifications, and these edits are duplications of all of the changes that have happened on the *trunk* since you first created your branch. At this point, your private branch is now synchronized with the trunk.

To synchronize your branch with its parent branch, follow these steps:

1. Go to **Tools** > **Merge**.
   The **Merge** wizard is opened.
2. Select the **Synchronize branch** option.
3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.
   a) Press the **Next** button.
      If the **Perform pre-merge best practices checks of the working copy target** option is selected, *the **Pre-Merge Checks** wizard page* is displayed.

      Note: If errors are found you need to solve them before proceeding.
4. Press the **Next** button.
   The **Synchronize branch** wizard page is displayed.
5. In the **Parent branch (URL)** text box, enter *the URL of the branch from which you created your branch*. This means that the URL must belong to the same repository as your working copy that was created from the child branch.

   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop down menu, which displays a history of previously used URLs.

   Tip: You can also specify a *peg revision* at the end of the URL (for example, `URL@rev1234`). The peg revision specifies both the peg revision of the URL and the latest revision that will be considered for merging. By default, the `HEAD` revision is assumed.
6. Optionally, if you want to *configure the options* for your merge, press the **Next** button.

The ***Merge Options*** *wizard page* is displayed that allows you to configure options for the operation.

Note: The **Ignore ancestry / Disable merge tracking** option is not available for this merge type, since a synchronization merge should always be recorded in the destination branch.

7. Press the **Merge** button.
   The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, *you may need to resolve conflicts* after making major changes.

Note: The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Reintegrate a Branch

There are some conditions that apply to reintegrate a branch:

- The server must support merge tracking.
- The source branch (to be reintegrated) must be coherently synchronized with its parent branch. This means that all revisions between the branching point and the last revision merged from the parent branch to the child branch must be merged to the latter one (there must be no missing revisions in-between).
- The working copy **must not** contain the following:
  - Local modifications.
  - A mixture of revisions (all items must point to the same revision).
  - Sparse directories (all directories must be of **infinity** depth).
  - Switched items.
- The revision of the working copy must be greater than or equal to the last revision of the parent branch with which the child branch was synchronized.

Tip: You can use *the pre-merge checks option* to make sure these conditions are fulfilled.

This method is useful when you have a feature branch on which the development has concluded and it should be merged back into its parent branch. Since you have kept the feature branch synchronized with its parent, the latest versions of them will be absolutely identical except for your feature branch changes. These changes can be reintegrated into the parent branch by using a working copy of it and the **Reintegrate a branch** option.

This method uses the *merge-tracking* features of Apache Subversion™ to automatically calculate the correct revision ranges and to perform additional checks that will ensure that the branch to be reintegrated has been fully updated with its parent changes. This ensures that you do not accidentally undo work that others have committed to the parent branch since the last time you synchronized the child branch with it. After the merge, all branch development will be completely merged back into the parent branch, and the child branch will be redundant and can be deleted from the repository.

Tip: Before reintegrating the child branch it is recommended to synchronize it with its parent branch one more time, to help avoid any possible conflicts.

To reintegrate a child branch into its parent branch, follow these steps:

1. Go to menu **Tools** > **Merge**.
   The **Merge** wizard is opened.
2. Select the **Reintegrate a branch** option.

   Note: This option is not available if the selected working copy item (or if it is a directory, any of the items inside of it) has any type of modification. This is because it is mandatory for the target item to have no modifications.
3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.
   a) Press the **Next** button.

If the **Perform pre-merge best practices checks of the working copy target** option is selected, *the **Pre-Merge Checks** wizard page* is displayed.

Note: If errors are found you need to solve them before proceeding.

4. Press the **Next** button.
   The **Reintegrate a branch** wizard page is displayed.
5. In the **Child branch (URL)** text box, enter *the URL of the child branch to be reintegrated*. This means that the URL must belong to the same repository as your working copy that was created from the parent branch.

   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop down menu, which displays a history of previously used URLs.

   Tip: You can also specify a *peg revision* at the end of the URL (for example, `URL@rev1234`). The peg revision specifies both the peg revision of the URL and the latest revision that will be considered for merging. By default, the HEAD revision is assumed.

   The ***Merge Options** wizard page* is displayed that allows you to configure options for the operation.

   Note: Since a *reintegrate merge* is so specialized, most of the merge options are not available, except for those in the **File Comparison** category.
6. Press the **Merge** button.
   The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, *you may need to resolve conflicts* after making major changes.

Note: The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Merge Two Different Trees

This merge type is useful when you need to duplicate changes from one child branch (for example, CB1) to another child branch (CB2) from the same parent branch. The SVN client will calculate the changes necessary to get from the HEAD revision of the parent branch (or the *trunk*) to the HEAD revision of one of its child branches (CB1), and apply those changes to your working copy of the other branch (CB2). The result is that the latter child branch (CB2) will also include the changes made on the original child branch (CB1), although that branch was not reintegrated into the parent branch.

This merge type could also be used to reintegrate a child branch back into its parent when the repository does not support *merge tracking*.

Note: If the server does not support *merge-tracking*, then this is the only way to merge a branch back to its parent.

1. Go to menu **Tools** > **Merge**.
   The **Merge** wizard is opened.
2. Select the option **Merge two different trees**.
3. It is recommended that you select the **Perform pre-merge best practices checks of the working copy target** option to make sure that the working copy target item is ready for the merge operation.
   a) Press the **Next** button.
      If the **Perform pre-merge best practices checks of the working copy target** option is selected, *the **Pre-Merge Checks** wizard page* is displayed.

      Note: If errors are found you need to solve them before proceeding.
4. Press the **Next** button.
   The **Merge two different trees** wizard page is displayed.
5. In the **From (starting URL and revision)** section enter *the URL of the first branch*.

You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop down menu, which displays a history of previously used URLs.

Tip: If you are using this method to merge a feature branch back to its parent branch, you need to start the merge wizard from within a working copy of the parent. In this field enter the full URL of the parent branch. This may sound wrong, but remember that the parent is the starting point to which you want to add the branch changes.

Note: If the URL belongs to a different repository than the working copy, the **Ignore ancestry / Disable merge tracking** option (in the ***Merge Options*** *wizard page*) will be selected automatically (and you cannot change this). This is because the *Subversion client cannot track changes between different repositories*.

Tip: You can also specify a *peg revision* at the end of the URL (for example, `URL@rev1234`). By default, the `HEAD` revision is assumed.

6. Enter the last revision number at which the two trees were synchronized by choosing between **HEAD revision** and **other revision**.
   - **HEAD revision** - Use this option if you are sure that no one else has committed changes since the last synchronization.
   - **other revision** - Use this option to input a specific revision number and avoid losing recent commits. You can use the **History** button to see a list of all revisions.
7. In the **To (ending URL and revision)** section enter *the URL of the second branch*.

   You may also click the **Browse** button to browse the repository and find the desired branch. If you have previously merged from this branch, then you can simply use the drop down menu, which displays a history of previously used URLs.

   Tip: If you are using this method to merge a feature branch back to its parent branch, enter the URL of the feature branch. This way, only the changes unique to this branch will be merged, since the branch should have been periodically synchronized with its parent.

   Attention: The URL must point to the same repository as the one in the **From (starting URL and revision)** field. Otherwise, the operation will not be allowed, since Subversion cannot compute changes between items from different repositories.

   Tip: You can also specify a *peg revision* at the end of the URL (for example, `URL@rev1234`). By default, the `HEAD` revision is assumed.
8. Select a revision to compute all changes committed up to that point by choosing between **HEAD revision** and **other revision**.
   - **HEAD revision** - This is the default selected revision.
   - **other revision** - Use this option if you want to enter a previous revision. You can use the **History** button to see a list of all revisions.
9. Optionally, if you want to *configure the options* for your merge, press the **Next** button.
   The ***Merge Options*** *wizard page* is displayed that allows you to configure options for the operation.

   Warning: If the **Ignore ancestry / Disable merge tracking** option is selected and you chose **all revisions** in the **Revisions to merge** section, revisions that were previously merged will also be included, which may result in conflicts.
10. Press the **Merge** button.
    The merge operation is performed.

If the merge is completed successfully, all the changes corresponding to the selected revisions should be merged in your working copy.

It is recommended to look at the results of the merge, in the working copy, to review the changes and see if it meets your expectations. Since merging can sometimes be complicated, *you may need to resolve conflicts* after making major changes.

Note: The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Merge Options

Here is the list of options that can be used when merging:

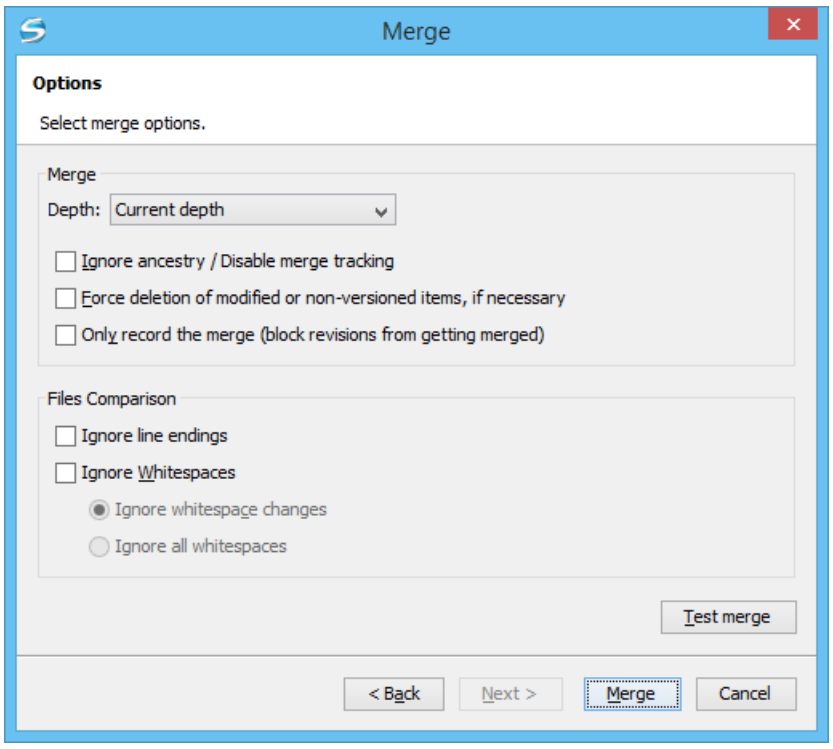

Figure 805: Merge Wizard - Advanced Options

- **Depth** (This option is applicable only for directories) - sets the depth of the merge operation. You can specify how far down into your working copy the merge should go by selecting one of the following values:
  - **Current depth** - Obeys the depths registered for the directories in the working copy that are to be switched.
  - **Recursive (infinity)** - Merges all the files and folders contained in the selected folder. This is the recommended depth for most users, to avoid incomplete merges and *subtree mergeinfo*.
  - **Immediate children (immediates)** - Merges only the child files and folders without recursing subfolders.
  - **File children only (files)** - Merges only the child files.
  - **This folder only (empty)** - Merges only the selected folder (no child files or folders are included).

  Note: The *depth* term is described in the *Sparse checkouts* section. The default depth is the current depth of the working copy item receiving the merge.
- **Ignore ancestry / Disable merge tracking** - Changes the way two items are merged if they do not share a common ancestry. Most merges involve comparing items that are ancestrally related to one another. However, occasionally you may want to merge unrelated items. If this option is not selected, the first item will be replaced with the second item. In these situations, you would want the merge to do a path-based comparison only, ignoring any relations between the items. For example, if two different files have the same name and are in the same relative location, deselecting the option replaces one of the files with the other one, and selecting it merges their contents.

  Note: If the URL of the merge source belongs to a different repository than the URL of the target working copy item (the one receiving the changes), this option is selected automatically (and you cannot change this). This is because the *Subversion client cannot track changes between different repositories*.
- **Force deletion of modified or non-versioned items, if necessary** - If not selected, when the merge operation involves deleting locally modified or non-versioned items, it will fail. This is done to prevent data loss. This option is only available if there are uncommitted changes in the working copy.
- **Only record the merge (block revisions from getting merged)** - Available when the ***Ignore ancestry / Disable merge tracking*** *option* is not selected. It enables a special mode of the merge operation that just records it in the local merge tracking information, without actually performing it (does not modify any file contents or the structure of your working copy). You might want to select this option for two possible reasons:

    - You made (or will make) the merge manually, and therefore need to mark the revisions as being merged to make the merge tracking system aware of them. This will exclude them from future merges.
    - You want to prevent one or more particular changes from being fetched in subsequent merges.
- **Ignore line endings** - Allows you to specify how the line ending changes should be handled. By default, all such changes are treated as real content changes, but you can ignore them if you select this option.
- **Ignore whitespaces** - Allows you to specify how the whitespace changes should be handled. By default, all such changes are treated as real content changes, but you can ignore them if you select this option.
    - **Ignore whitespace changes** - Ignores changes in the amount of whitespaces or to their type (for example, when changing the indentation or changing tabs to spaces).

      Note: Whitespaces that were added where there were none before, or that were removed, are still considered to be changes.
    - **Ignore all whitespaces** - Ignores all types of whitespace changes.
- **Test merge** - Performs a dry run of the merge operation, allowing you to *preview* it without actually performing the merge. In the **Console** view you will see a list of the working copy items that will be affected and how they will be affected. This is helpful in detecting whether or not a merge will be successful, and where conflicts may occur.

Resolving Merge Conflicts

After the merge operation is finished, it is possible to have some items in conflict. This means that some incoming modifications for an item could not be merged with the current working copy version. If there are such conflicts, the **Merge conflicts** dialog box will appear, presenting the items that are in conflict. This dialog box offers you choices for resolving the conflicts.

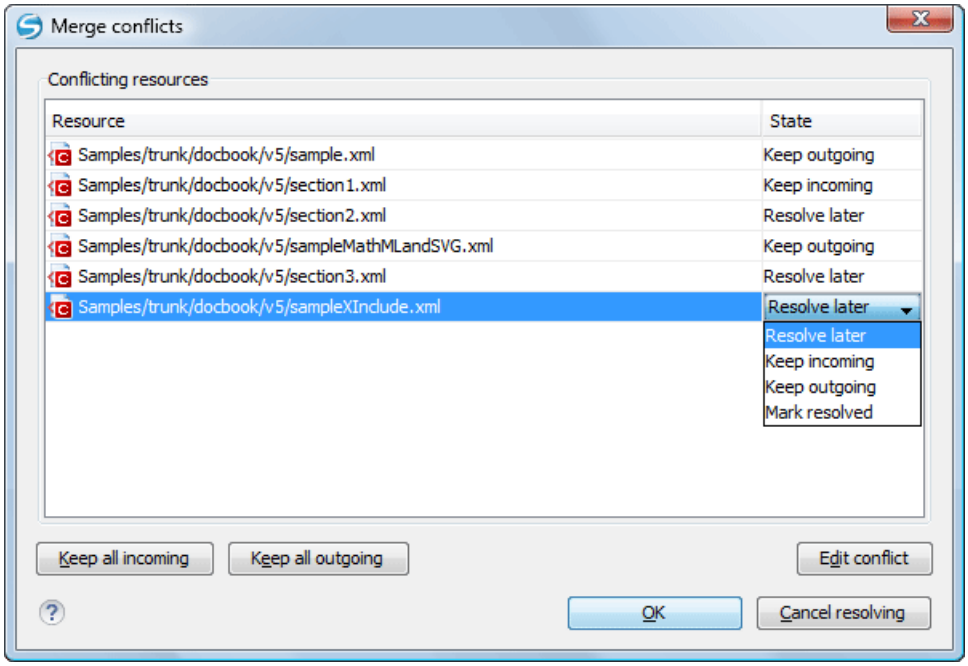

Figure 806: Merge Conflicts Dialog Box

The options to resolve a conflict are as follows:

- **Resolve later** - Used for leaving the conflict as it is, to manually resolve it later.
- **Keep incoming** - This option keeps all the incoming modifications and discards all current ones from your working copy.
- **Keep outgoing** - This option keeps all current modifications from your working copy and discards all incoming ones.
- **Mark resolved** - You should choose this option after you have manually solved the conflict, to instruct the Subversion that it was resolved. To do this, use the **Edit conflict** button, which displays a dialog box that presents the contents of the conflicting items (the content of the working copy version versus the incoming version).

Sub-tree Merges

It is recommended to perform a merge on the whole working copy (select its root directory when triggering the operation) to avoid *sub-tree mergeinfo*. *Sub-tree mergeinfo* is the *mergeinfo* recorded to describe a *sub-tree merge*. That is, a merge done directly to a child of a branch root that might be needed in certain situations. There is nothing special about *sub-tree merges* or *sub-tree mergeinfo* except that the complete record of merges to a branch may not be contained solely in the *mergeinfo* on the branch root and you may have to look to any *sub-tree mergeinfo* to get a full accounting. Fortunately, Subversion does this for you and rarely will you need to look for it.

Merging from Foreign Repositories

Subversion supports merging from foreign repositories. While all merge source URLs must point to the same repository, the merge target (from the working copy) may come from a different repository than the source. However, copies made in the merge source will be transformed into plain additions in the merge target. Also, *merge-tracking* is not supported for merges from foreign repositories.

Note: When performing merges from repositories other than the one corresponding to the target item (from the working copy), the ***Ignore ancestry / Disable merge tracking*** *option* in the ***Merge Options*** *wizard page* will be selected automatically (and you cannot change this).

General Merge Recommendations

As a recommendation, you should only merge into clean working copies that **do not** contain any of the following:

- Modifications.
- Sparse directories (all directories must be of depth *infinity*).
- Switched items.

Important: This recommendation becomes mandatory when performing a *reintegrate merge* operation. Also, trying to merge to mixed-revision working copies will fail in all types of merge operations.

Remember: The merge result is only in your local working copy and needs to be committed to the repository for it to be available to others.

Switch the Repository Location

The **Switch** action is useful when the repository location of a working copy, or an already committed item in the working copy, must be changed within the same repository. The action is available on the **Tools** menu when a versioned resource is selected in the current working copy that is displayed in the ***Working Copy*** *view*.

Note: *External* items cannot be switched using this action. Instead, change the value of the `svn:externals` property set on the parent directory of the external item and update the parent directory.

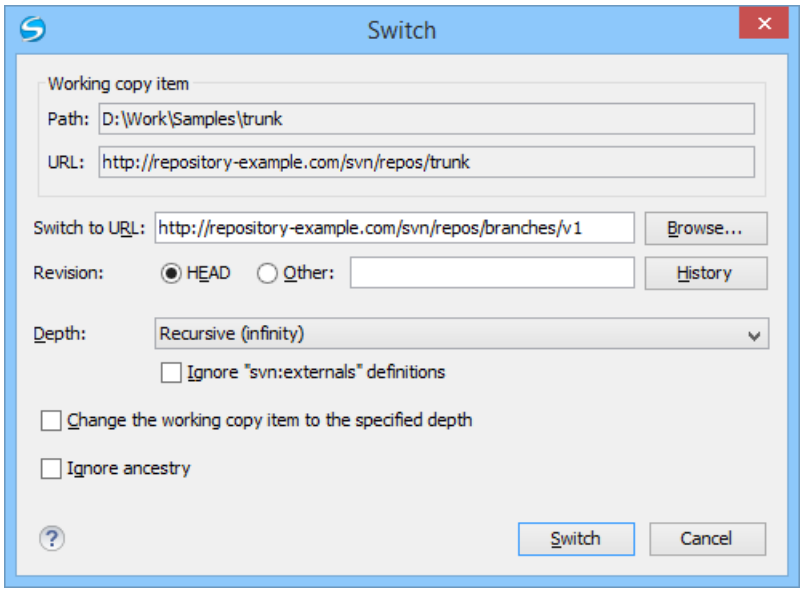

Figure 807: Switch Dialog Box

The following options can be configured in the **Switch** dialog box:

Switch to URL

The new location in the same repository you are switching to.

Tip: You can switch to items that were deleted, moved, or replaced, by specifying the original URL (before the item was removed) and use a *peg revision* at the end (for example, URL@rev1234).

Note: For items that are already *switched* that you want to switch back, the proposed URL is the original location of the item.

Revision

The specific version of the location that you are switching to.

Depth - (This option is applicable only for directories)

Current depth

Obeys the depths registered for the directories in the working copy that are to be switched.

Recursive (infinity)

Switches the location of the selected folder and all of its files and folders.

Immediate children (immediates)

Switches the location of the selected folder and its child files and folders without recursing subfolders.

File children only (files)

Switches the location of the selected folder and its child files.

This folder only (empty)

Switches the location of the selected folder (no child files or folders are included).

Ignore "svn:externals" definitions

When selected, external items are ignored in the switch operation. This option is only available if you choose the **Current depth** or **Recursive (infinity)** depth.

Change the working copy item to the specified depth

Changes the *sticky* depth on the directory in the working copy.

Ignore ancestry

When not selected, the SVN system does not allow you to switch to a location that does not share a common ancestry with the current location. If selected, the SVN does not check for a common ancestry.

Relocate a Working Copy

Sometimes the base URL of the repository is changed after a working copy is checked out from that URL. For example, if the repository itself is moved to a different server. In such cases, you do not have to check out a working copy from the new repository location. It is easier to change the base URL of the root folder of the working copy to *the new URL of the repository*.

Note: *Peg revisions* have no effect for this operation.

This **Relocate** action is available in the **Tools** menu when selecting the root item of the working copy.

Note: *External* items that are defined using absolute URLs and that point to the same repository as the working copy are not affected by the **Relocate** action (the URL is not updated). To relocate these items, change the value of the `svn:externals` property for each external item (set on their parent directories). For example, if an external item is defined as `externalDir http://host/path/to/repo/to/dir` and the repository was moved to another server (`host2`) and its protocol changed to `https`, then the value of the property needs to be updated to `externalDir https://host2/path/to/repo/to/dir`.

Tip: If you edit external items using the method described in the previous note, on the next update the system will try to fetch the external items again. To avoid this, you can invoke the **Relocate** action on each of these external items.

Patches

This section explains how to work with patches in Syncro SVN Client.

What is a Patch

Suppose you are working with a set of XML files that you want to tag the project and distribute releases to other team members. While working on the project and correcting problems, you may need to distribute the corrections to other team members. In this case, you can distribute a patch (a collection of differences) that would correct the problems when applied over the last distribution. By default, the Syncro SVN Client generates patches in *the Unified Diff format*, but it can also use *the Git format*.

Creating a patch in Apache Subversion™ implies the access to either two revisions of a versioned item, or two different versioned items from the repository:

- *Two revisions of a version item* - the item can be local or remote and you can select two versions of it. This also applies when you need to generate a patch that only contains the changes in the working copy that were not yet committed.
- *Two different versioned items from the repository* - the items are remote and you need to specify a revision for both.

Warning: The resulting patch file may contain content that was written using a mix of encodings, based upon the encodings of the files that were compared. If you open the generated patch file in a text editor, it may result in unrecognizable content.

Generating a Patch - Local Items

Based on a versioned item (already committed or scheduled for addition) in the working copy, you can generate patches that contain the local changes, the differences between a specific revision of that item and the item itself, or differences between the pristine item and another item from the repository. There are four options for generating a patch based upon local items.

To open the **Create patch** wizard, use the  **Create patch** action from the **Tools** menu or from the contextual menu in the **Modified**, **Incoming**, **Outgoing**, or **Conflicts** modes.

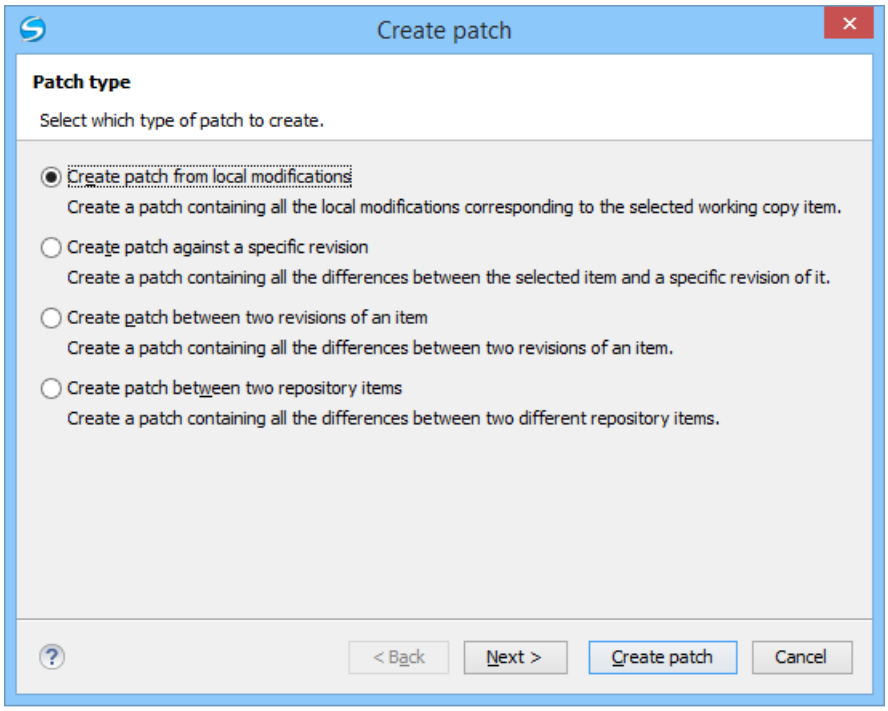

Figure 808: Create Patch Wizard - Local Items

Create Patch from Local Modifications

This is the most commonly used type of patch and contains only the local changes for the selected item.

This option is useful if you want to share changes with other team members and you are not yet ready to commit them. This option is only available for local items that contain modifications. It is not available for items in which the local file status is *unversioned or ignored, and in some cases missing or obstructed*.

The steps are as follows:

1. Go to menu **Tools** > **Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch from local modifications** option in the dialog box.
3. Optionally, if you want *to configure the options* for your patch, press the **Next** button.

   This options page does not remember your selections when creating future patches. It will revert to the default values.

   The **Options** wizard page is displayed.
4. Press the **Create patch** button.

   If the patch is applied on a folder of the working copy and that folder contains *unversioned files*, this step of the wizard offers the option of selecting the ones that will be included in the patch.

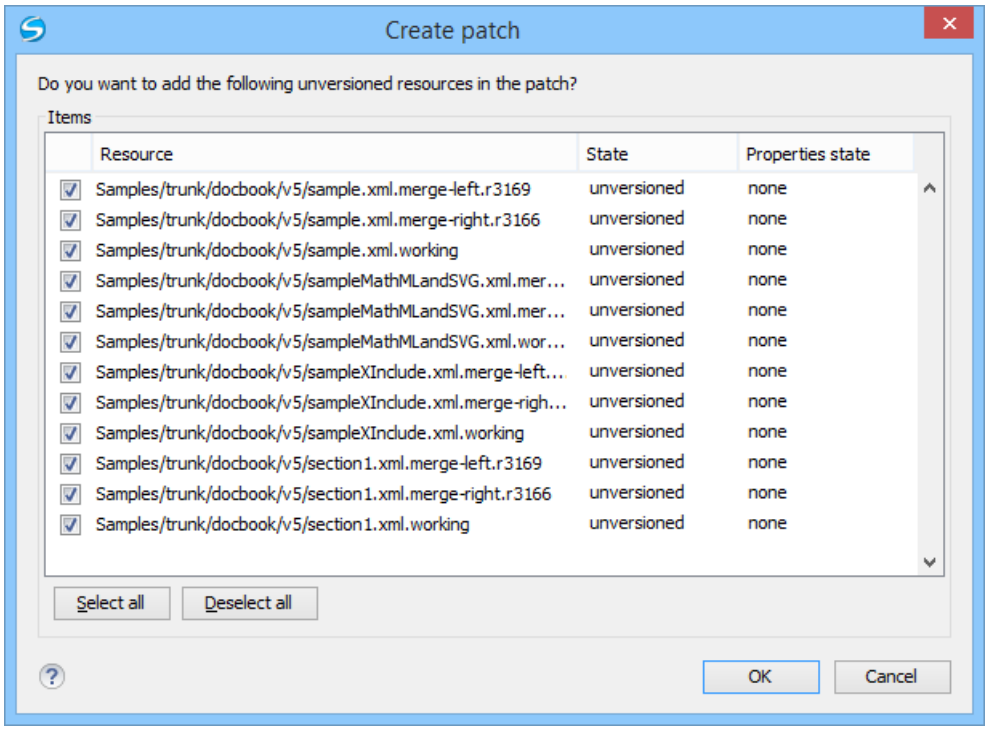

Figure 809: Create Patch Dialog Box - Add Unversioned Resources

The patch is created and stored in the path specified in *the **Output** section of the **Options** page* or in the default location.

Create Patch Against a Specific Revision

This type of patch contains changes between an old revision and the current content from the selected item within the working copy.

This option is useful if you want to obtain differences between an older revision and the current state of the working copy (for instance, to test how current changes apply to an older version).

The steps are as follows:

1. Go to menu **Tools** > **Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch against a specific revision** option in the dialog box.
3. Press the **Next** button.
   The second step of the wizard is opened:

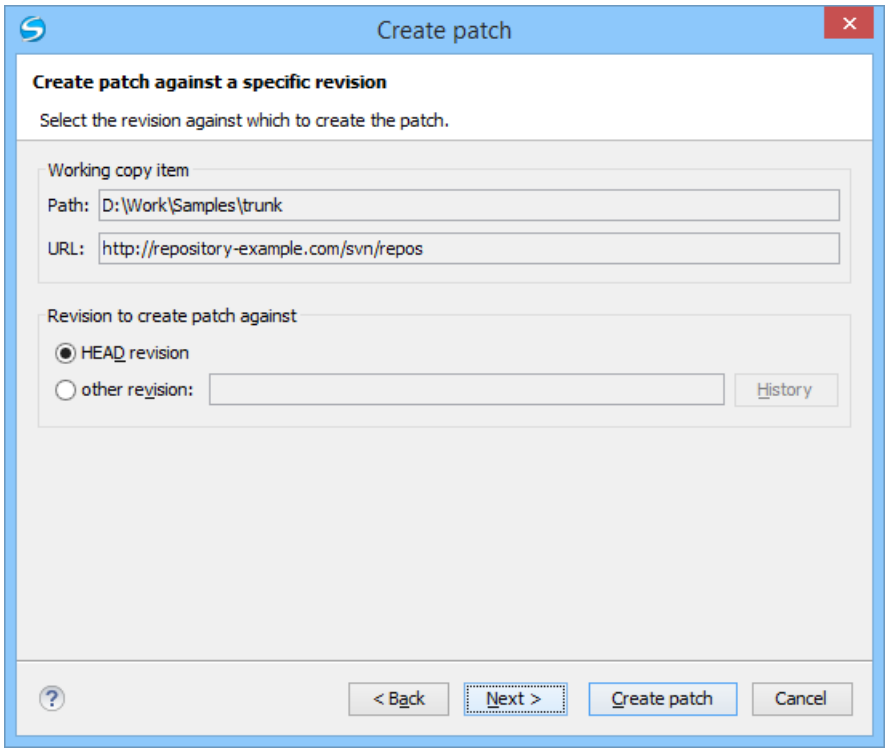

Figure 810: Create Patch Wizard - Step 2

4. Select the **revision to create patch against**.

   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can press *the **History** button* to display a list of the item revisions.

   Note: If the **revision to create patch against** is older than the revision for which the working copy item was updated, the patch will include changes that were made **after** the selected revision.

5. Optionally, if you want *to configure the options* for your patch, press the **Next** button.

   This options page does not remember your selections when creating future patches. It will revert to the default values.

   The **Options** wizard page is displayed.

6. Press the **Create patch** button.
   The patch is created and stored in the path specified in *the **Output** section of the **Options** page* or in the default location.

Create Patch Between Two Revisions of an Item

This type of patch contains historical changes between two revisions of a selected item.

This option is useful if you want to share changes between two revisions with other team members.

Tip: If you need to generate a patch between two revisions of a previously *deleted*, *moved*, or *replaced* item, you should use *the **Create patch between two repository items** option* instead.

The steps are as follows:

1. Go to menu **Tools** > **Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two revisions of an item** option in the dialog box.
3. Press the **Next** button.
   The second step of the wizard is opened:

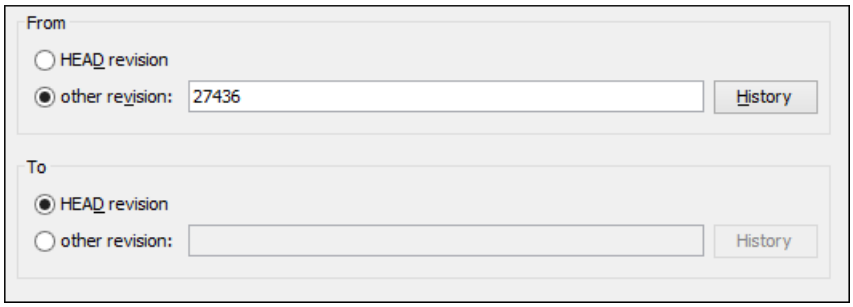

Figure 811: Create Patch Wizard - Step 2

4. Select the starting and ending revisions in the **From** and **To** sections.

   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can press *the **History** button* to display a list of the item revisions.

   Note: The patch will only include changes between the two specified revisions, starting with the changes that were made **after** the older revision.

   Tip: If you want to reverse changes done between two revisions by using a patch file, you can specify the newer revision in the **From** section and the older version in the **To** section.

5. Optionally, if you want *to configure the options* for your patch, press the **Next** button.

   This options page does not remember your selections when creating future patches. It will revert to the default values.

   The **Options** wizard page is displayed.

6. Press the **Create patch** button.
   The patch is created and stored in the path specified in *the **Output** section of the **Options** page* or in the default location.

Create Patch Between Two Repository Items

This type of patch contains changes between one version of an item and a specific version of another item.

This option is useful for generating a patch that contains changes between existing, or even previously deleted, moved, or replaced items from different branches. This is the default option when you do not have a working copy loaded, when no repository items are selected, or when exactly two repository items of the same kind are selected.

Tip: To access an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg revision* at the end (for example, `URL@rev1234`).

The steps are as follows:

1. Go to menu **Tools** > **Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two repository items** option in the dialog box.
3. Press the **Next** button.
   The second step of the wizard is opened:

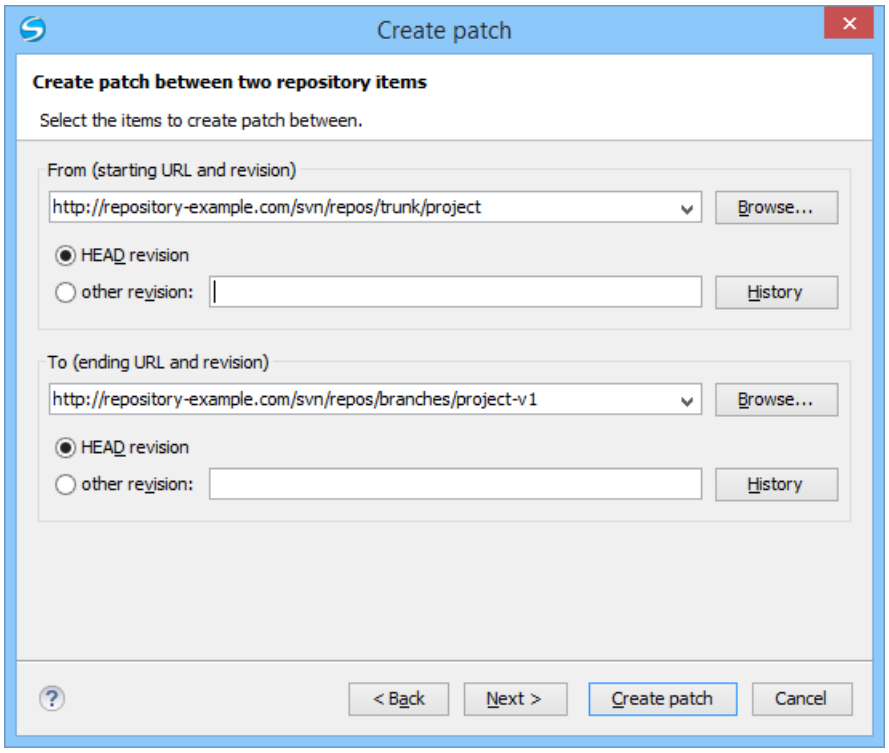

Figure 812: Create Patch Wizard - Step 2

4. Select *the starting and ending URLs* and revisions in the **From** and **To** sections.

   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can press *the **History** button* to display a list of the item revisions.

   Important: Both URLs must point to items from the same repository.

   Note: If you use a *peg* revision in the URL field, anything specified in the **other revision** field is ignored.
5. Optionally, if you want *to configure the options* for your patch, press the **Next** button.

   This options page does not remember your selections when creating future patches. It will revert to the default values.

   The **Options** wizard page is displayed.
6. Press the **Create patch** button.
   The patch is created and stored in the path specified in *the **Output** section of the **Options** page* or in the default location.

Generating a Patch - Remote Items

Based on a repository item, you can generate patches that contain the differences between two specific revisions of that item, or between a revision of that same item and another revision of another item from the repository. There are two options for generating a patch based upon remote items.

To open the **Create patch** wizard, use the **Create patch** action from the **Tools** menu.

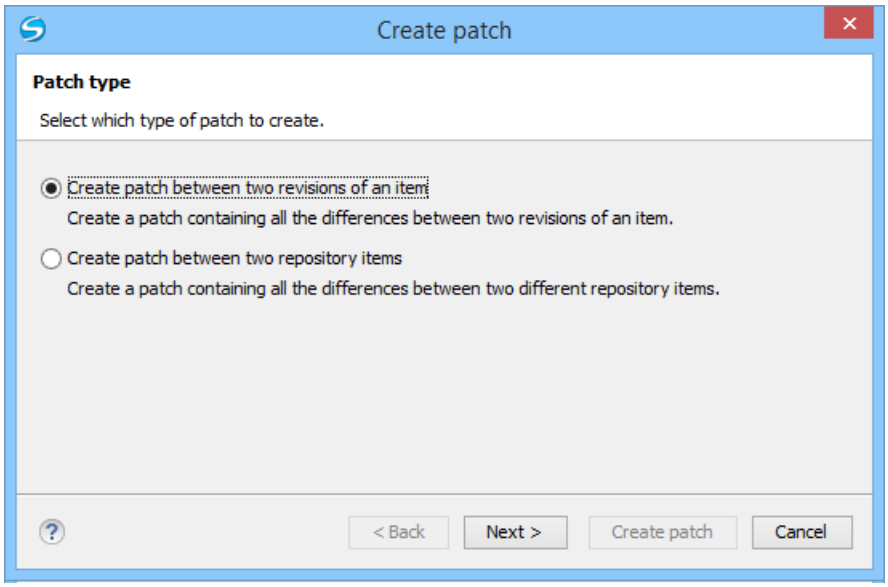

Figure 813: Create Patch Wizard - Remote Items

Create Patch Between Two Revisions of an Item

This type of patch contains historical changes between two revisions of a selected item.

This option is useful if you want to share changes between two revisions with other team members.

Tip: If you need to generate a patch between two revisions of a previously *deleted*, *moved*, or *replaced* item, you should use *the **Create patch between two repository items** option* instead.

The steps are as follows:

1. Go to menu **Tools** > **Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two revisions of an item** option in the dialog box.
3. Press the **Next** button.
   The second step of the wizard is opened:

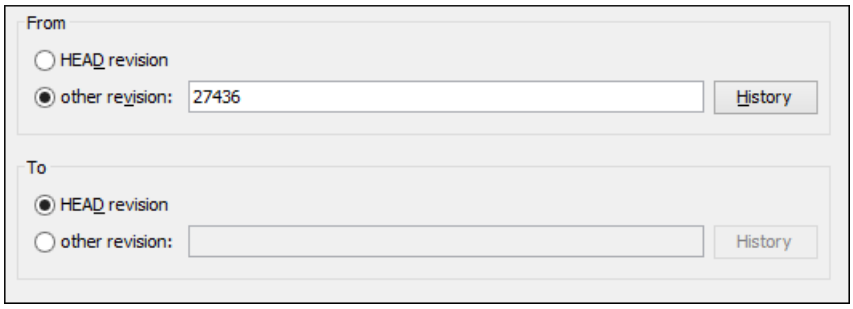

Figure 814: Create Patch Wizard - Step 2

4. Select the starting and ending revisions in the **From** and **To** sections.

   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can press *the **History** button* to display a list of the item revisions.

   Note: The patch will only include changes between the two specified revisions, starting with the changes that were made **after** the older revision.

   Tip: If you want to reverse changes done between two revisions by using a patch file, you can specify the newer revision in the **From** section and the older version in the **To** section.
5. Optionally, if you want *to configure the options* for your patch, press the **Next** button.

   This options page does not remember your selections when creating future patches. It will revert to the default values.

The **Options** wizard page is displayed.

6. Press the **Create patch** button.
   The patch is created and stored in the path specified in *the **Output** section of the **Options** page* or in the default location.

Create Patch Between Two Repository Items

This type of patch contains changes between one version of an item and a specific version of another item.

This option is useful for generating a patch that contains changes between existing, or even previously deleted, moved, or replaced items from different branches. This is the default option when you do not have a working copy loaded, when no repository items are selected, or when exactly two repository items of the same kind are selected.

Tip: To access an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg revision* at the end (for example, `URL@rev1234`).

The steps are as follows:

1. Go to menu **Tools** > **Create patch**.
   This opens the **Create patch** wizard.
2. Select the **Create patch between two repository items** option in the dialog box.
3. Press the **Next** button.
   The second step of the wizard is opened:

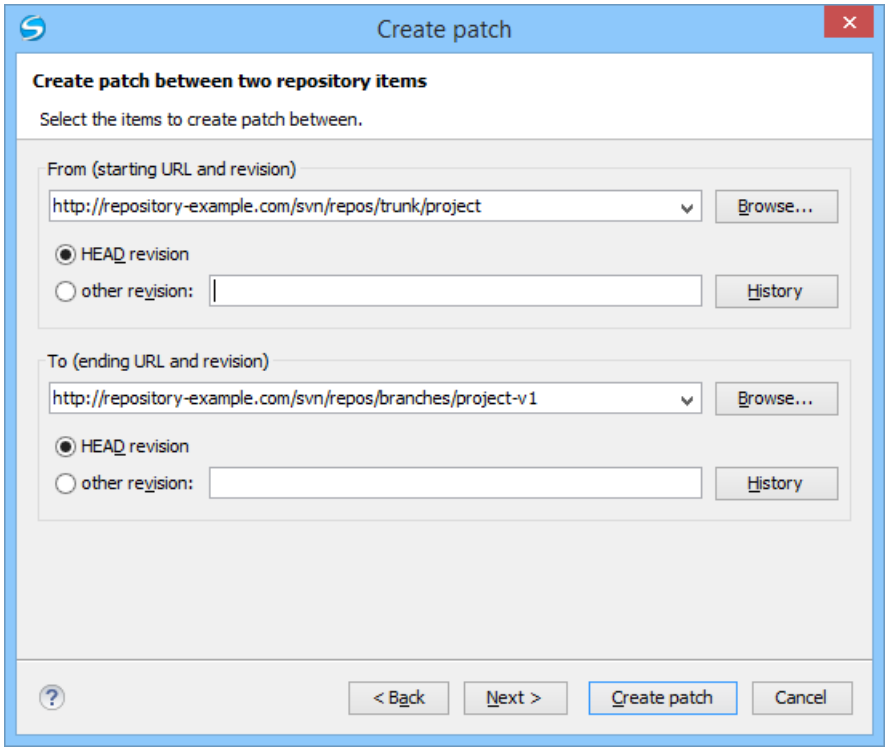

Figure 815: Create Patch Wizard - Step 2

4. Select *the starting and ending URLs* and revisions in the **From** and **To** sections.
   You can select between the **HEAD revision** and a specific revision number. For the **other revision** option, you can press *the **History** button* to display a list of the item revisions.

   Important: Both URLs must point to items from the same repository.

   Note: If you use a *peg* revision in the URL field, anything specified in the **other revision** field is ignored.
5. Optionally, if you want *to configure the options* for your patch, press the **Next** button.
   This options page does not remember your selections when creating future patches. It will revert to the default values.
   The **Options** wizard page is displayed.

6. Press the **Create patch** button.
   The patch is created and stored in the path specified in *the **Output** section of the **Options** page* or in the default location.

Patch Options

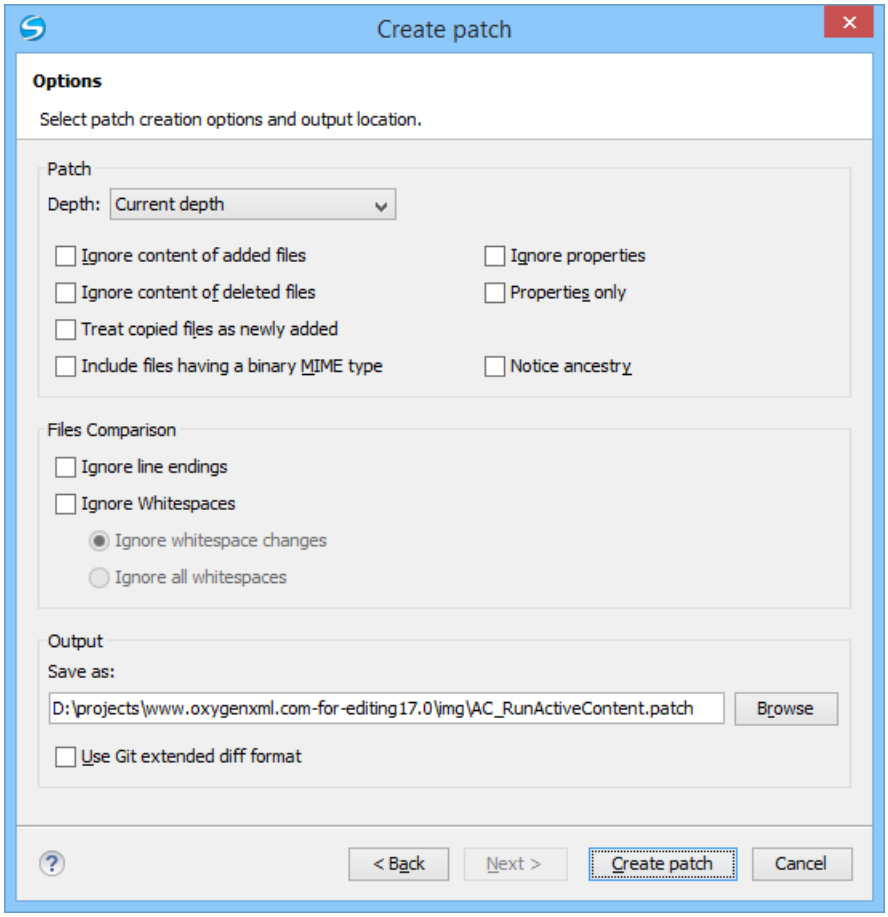

Figure 816: Create Patch Wizard - Options

Patch Section

Depth - (This option is applicable only for directories)

Current depth

The depth of recursing the folder for creating the patch is the same as the depth of that same folder in the working copy (available only when generating patches that contain changes from the working copy).

Recursive (infinity)

The patch is created on all the files and folders contained in the selected folder.

Immediate children (immediates)

The patch is created only on the child files and folders without recursing subfolders.

File children only (files)

The patch is created only on the child files.

This folder only (empty)

The patch is created only on the selected folder (no child file or folder is included in the patch).

Ignore content of added files

When selected, the patch file does not include the content of the *added* items. This option corresponds to the `--no-diff-added` option of the `svn diff` command.

Ignore content of delete files

When selected, the patch file does not include the content of the *deleted* items. This option corresponds to the `--no-diff-deleted` option of the `svn diff` command.

Treat copied files as newly added

When selected, copied items are treated as new, rather than comparing the items with their sources. This option corresponds to the `--show-copies-as-adds` option of the `svn diff` command.

Include files having a binary MIME type

When selected, the application is forced to compare items that are considered binary file types. This option corresponds to the `--force` option of the `svn diff` command.

Ignore properties

When selected, differences in the properties of items are ignored. This option corresponds to the `--ignore-properties` option of the `svn diff` command.

Properties only

When selected, only differences in the properties of the items are included in the patch file (file content is ignored). This option corresponds to the `--properties-only` option of the `svn diff` command.

Note: The **Ignore properties** and **Properties only** options are mutually exclusive.

Notice ancestry

If selected, the SVN common ancestry is taken into consideration when calculating the differences. This option corresponds to the `--notice-ancestry` option of the `svn diff` command.

Files Comparison Section

Ignore line endings

If selected, the differences in line endings are ignored when the patch is generated. This option corresponds to the `--ignore-eol-style` option of the `svn diff` command.

Ignore whitespaces

If selected, it allows you to specify how the whitespace changes should be handled. When selected, you can then choose between two options:

- **Ignore whitespace changes** (`--ignore-space-change`) - Ignores changes in the amount of whitespaces or to their type (for example, when changing the indentation or changing tabs to spaces).

  Note: Whitespaces that were added where there were none before, or that were removed, are still considered to be changes.
- **Ignore all whitespaces** (`--ignore-all-space`) - Ignores all types of whitespace changes.

Output Section

Save as

The patch will be created and saved in the specified file.

Use Git extended diff format

When selected, the patch is generated using the *Git* format. This option corresponds to the `--git` option of the `svn diff` command.

Working with Repositories

This section explains how to locate and browse SVN repositories in Syncro SVN Client.

Importing Resources Into a Repository

Importing resources into a repository is the process of copying local files and directories into a repository so that they can be managed by an Apache Subversion™ server. If you have already been using Subversion and you have an existing working copy you want to use, then you will likely want to follow the procedure for *using an existing working copy*.

The **Import folder** and **Import Files** actions are available from the **Import** submenu of the **Repository** menu or of the contextual menu in the **Repositories** view. These actions open a dialog box that allow you to select the directories or files that will be imported into the selected repository location.

The **Import folder** action opens the **Import folder** dialog box.

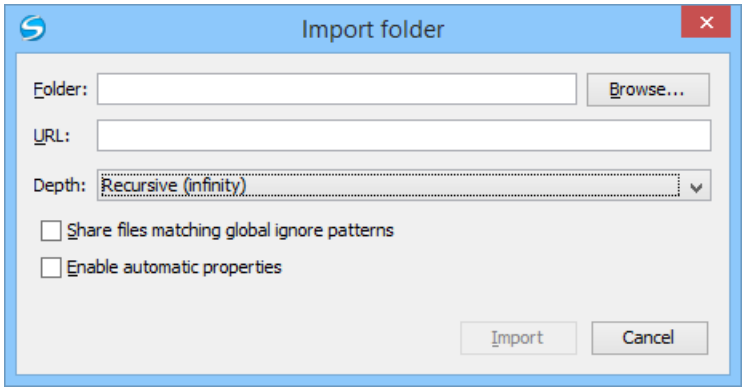

Figure 817: Import Folder Dialog Box

You can configure the following options:

Folder

Specify *the local folder* by using the text box or the **Browse** button. This folder should not be empty or already under version control.

Important: By default, the SVN system only imports the content of the specified folder, and not the folder itself. Therefore, it is recommended to use the **Browse** button to select the local folder so that the client will automatically append the name of it to the specified URL.

URL

Specify *the repository location* that will be used to access the folder to be imported.

Note: *Peg revisions* have no effect for this operation since it is used to send information to the repository.

Attention: If the new location already exists, make sure that it is an empty directory to avoid mixing your project content with other files (if items exist with the same name, an error will occur and the operation will not proceed). Otherwise, if the address does not exist, it is created automatically.

Depth

Recursive (infinity)

Imports all the files and folders contained in the selected folder.

Immediate children (immediates)

Imports only the child files and folders without recursing subfolders.

File children only (files)

Imports only the child files.

This folder only (empty)

Imports only the selected folder (no child file or folder is included).

Share files matching global ignore patterns

When selected, the file names that match the patterns defined in either of the following locations are also imported into the repository:

- The `global-ignores` property in *the SVN configuration file*.
- The ***File name ignore patterns*** *option* in the ***SVN*** *>* ***Working Copy*** *preferences page*.

Enable automatic properties/Disable automatic properties

Enables or disables automatic property assignment (per runtime configuration rules), overriding the `enable-auto-props` runtime configuration directive, defined in *the SVN configuration file*.

Note: This option is available only when there are defined properties to be applied automatically for newly added items under version control. You can define these properties in the SVN `config` file (in the `auto-props` section). Based on the value of the `enable-auto-props` runtime configuration directive, the presented option is either **Enable automatic properties**, or **Disable automatic properties**.

Exporting Resources From a Repository

This is the process of taking a resource from the repository and saving it locally in a clean form, with no version control information. This is very useful when you need a clean build for an installation kit.

The **Export** dialog box is similar to the **Check out** dialog box:

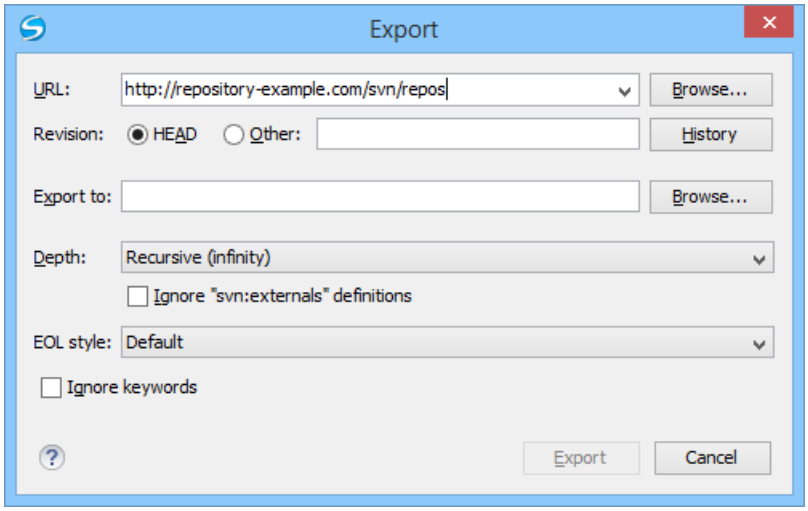

Figure 818: Export from Repository Dialog Box

You can configure the following options:

URL

Specify *the source directory from the repository* by using the text box or the **Browse** button.

Tip: To export an item that was deleted, moved, or replaced, you need to specify the original URL (before the item was removed) and use a *peg revision* at the end (for example, URL`@rev1234`).

Note: The content of the selected directory from the repository and not the directory itself will be exported to the file system.

Revision

You can choose between the **HEAD** or **Other** revision. If you need to export a specific revision, specify it in the **Other** text box or use the **History** button and choose a revision from the **History** dialog box.

Export to

Specify *the location where you want to export* the repository directory by typing the local path in the text box or by using the **Browse** button. If the specified local path does not point to an existing directory, it will automatically be created.

Important: By default, the SVN system only exports the content of the directory specified by the URL, and not the directory itself. Therefore, it is recommended to use the **Browse** button to select the *export* location so that the client will automatically append the name of the remote directory to the path of the selected directory.

Warning: The destination directory should be empty. If files exist, they will be overwritten by exported files with matching names.

Depth

Recursive (infinity)

Exports all the files and folders contained in the selected folder.

Immediate children (immediates)

Exports only the child files and folders without recursing subfolders.

File children only (files)

Exports only the child files.

This folder only (empty)

Exports only the selected folder (no child file or folder is included).

Ignore "svn:externals" definitions

When selected, external items are ignored in the export operation. This option is only available if you choose the **Recursive (infinity)** depth.

EOL style

Defines the *end-of-line (EOL)* marker that should be used when exporting files that have the value or the `svn:eol-style` property set to `native`. You can choose between the following styles:

- **Default** - It uses the system-specific *end-of-line* marker.
- **CRLF** - The Windows-specific *end-of-line* marker (*carriage return - line feed*).
- **LF** - The Unix / OS X-specific *end-of-line* marker (*line feed*).
- **CR** - The Mac OS 9 (or older)-specific *end-of-line* marker (*carriage return*).

Ignore keywords

When selected, the export operation does not expand the *SVN keywords* found inside the files.

Copy / Move / Delete Resources From a Repository

Once you have a location defined in the ***Repositories*** *view*, you can run commands (such as copy, move, and delete) directly on the repository. The commands correspond to the following actions in the contextual menu:

The **Copy to** and **Move to** action allows you to copy and move individual or multiple resources to a specific directory from the *HEAD* revision of the repository.

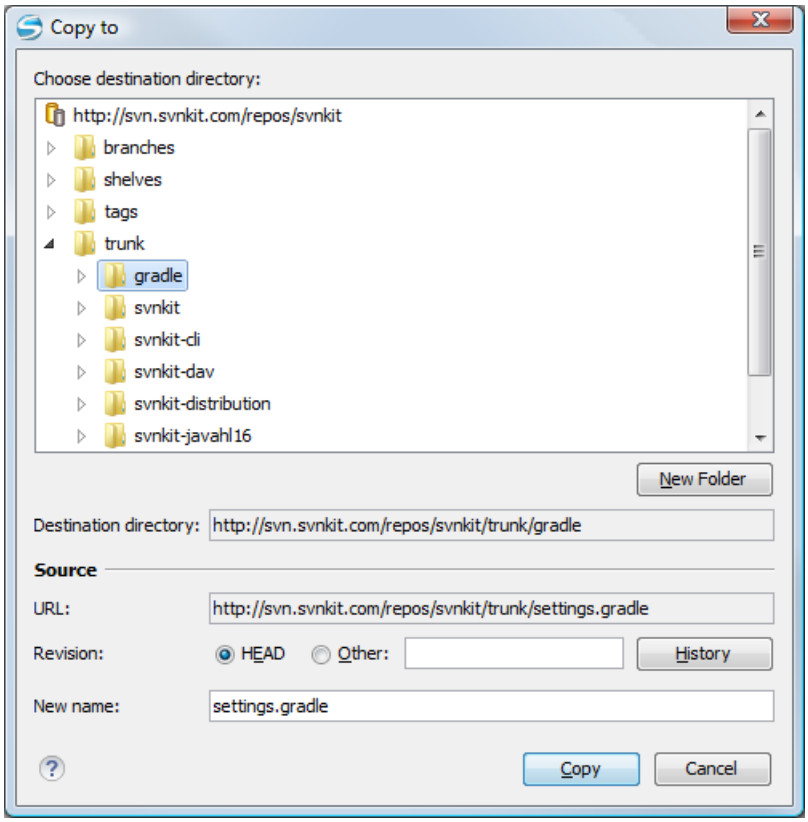

Figure 819: Copy/Move Items in Repository

The dialog box used to copy or move items allows you to browse the *HEAD* revision of the repository and select the destination of the items, presenting its repository URL below the tree view.

The **Source** section presents relevant options regarding the item(s) that you move or copy:

- **URL** - This field is displayed only if you copy/move a single item.
- **Revision** - Presents the revision from which you copy one or more items, allowing you to also choose another revision.

  Note: Since only items from the HEAD revision can be moved, the **Revision** options are not presented for the **Move to** action.

  Note: When you copy a single item while browsing a revision other than *HEAD*, the **Revision** options present this revision but does not allow you to change it. The same applies if copying multiple items.
- **New name** - This option is presented when you copy or move a single item, allowing you to also rename it.

Another useful action is **Delete**, allowing you to erase resources directly from the repository.

All three actions are commit operations and you will be prompted with the **Commit message** dialog box.

Sparse Checkout

Sometimes you only need to check out certain parts of a directory tree. In this case, you can check out the top directory (using the***Check out*** *action from the* ***Repositories*** *view*) and then recursively update only the needed directories (using the ***Update*** *action from the* ***Working Copy*** *view*). Each directory then has a depth set to it, with four possible values:

- **Recursive (infinity)** - Updates all descendant directories and files recursively.
- **Immediate children (immediates)** - Updates the directory, including direct child directories and files, but does not populate the child directories.
- **File children only (files)** - Updates the directory, including only child files without the child directories.
- **This folder only (empty)** - Updates only the selected directory, without updating any children.

For some operations, you can use as depth the current depth registered on the directories from the working copy (the value **Current depth**). This is the depth value defined in a previous check out or update operation.

The sparse checked out directories are presented in the ***Working Copy*** *view* with a marker corresponding to each depth value, in the top left corner, as follows:

-  **Recursive (infinity)** - This is the default value and it is has no mark. The directory has no limiting depth.
-  **Immediate children (immediates)** - The directory is limited to direct child directories (without contents) and files.
-  **File children only (files)** - The directory is limited to direct child files only.
-  **This folder only (empty)** - The directory has *empty* depth set.

A depth set on a directory means that some operations process only items within the specified depth range. For example, **Synchronize** on a working copy directory reports the repository modified items within the depth set on the directory and those existing in the working copy outside of this depth.

The depth information is also presented in the **SVN Information** dialog box and in the tool tip displayed when hovering a directory in the **Working Copy** view.

Syncro SVN Client Views

The main working area occupies the center of the application window, which contains the most important views:

- *Repositories View*
- *Working Copy View*
- *History View*
- *Console View*

The other views that support the main working area are also presented in this section.

Repositories View

The **Repositories** view allows you to define and manage Apache Subversion™ repository locations and browse repositories. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

If no connections to your repository are available, you can *add a new repository location*. Repository files and folders are presented in a tree view with the repository locations at the first level, where each location represents a connection to a specific repository. More information about each resource is displayed in a tabular form:

- **Date** - Date when the resource was last modified.
- **Revision** - The revision number at the time the resource was last modified.
- **Author** - Name of the person who made the last modification on the resource.
- **Size** - Resource size on disk.
- **Lock information** - Information about the lock status of a file. When a repository file is locked by a user the icon is displayed in this column. If no icon is displayed the file is not locked. The tooltip of this column displays the details about the lock:
  - **Owner** - The name of the user who created the lock.
  - **Date** - The date when the user locked the file.
  - **Expires on** - Date when the lock expires. Lock expiry policy is set in the repository options, on the server side.
  - **Comment** - The message attached when the file was locked.
- **Type** - Contains the resource type or file extension.

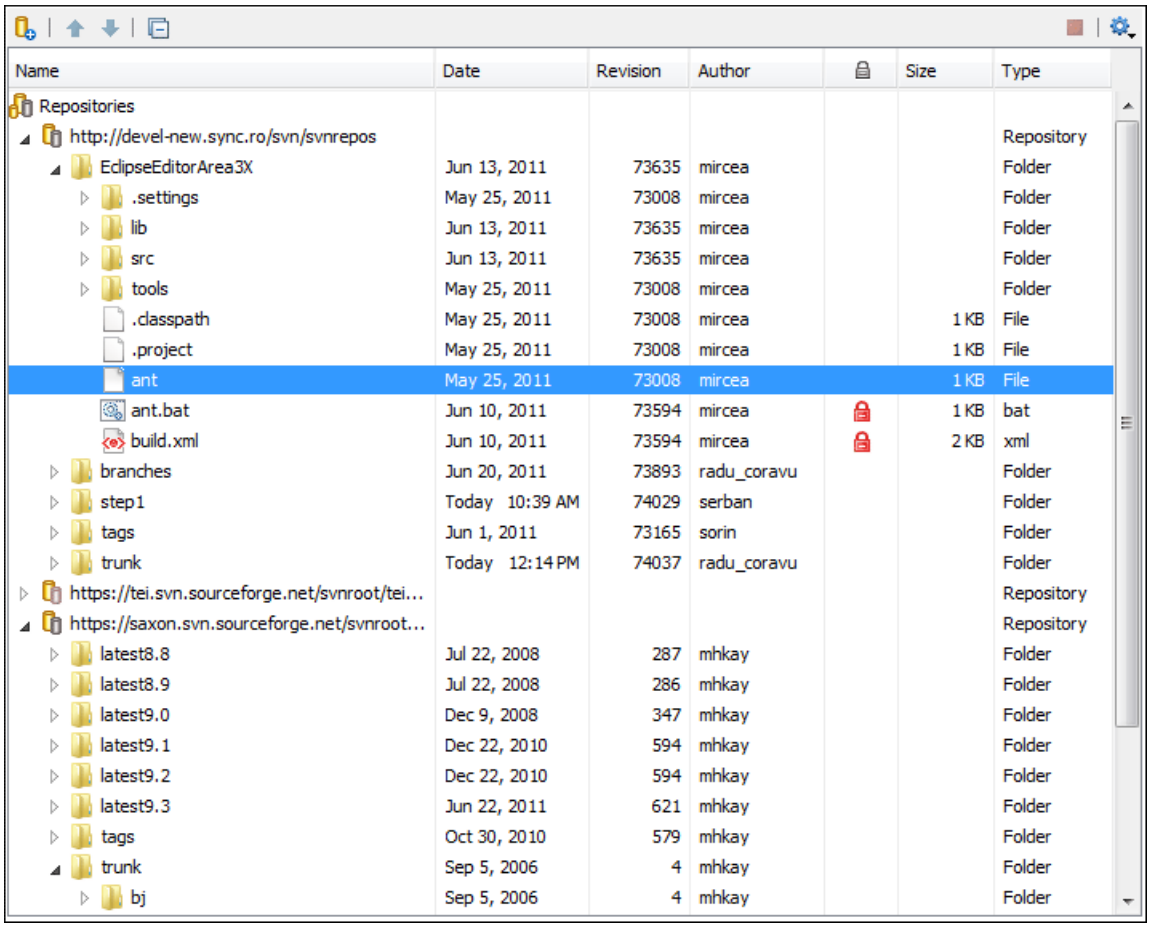

Figure 820: Repositories View

Toolbar

The **Repositories** view's toolbar contains the following buttons:

- **New Repository Location** - Allows you to enter a new repository location by means of the **Add SVN Repository** dialog box.
- **Move Up** - Move the selected repository up one position in the list of repositories in the **Repositories** view.
- **Move Down** - Move the selected repository down one position in the list of repositories in the **Repositories** view.
- **Collapse all** - Collapses all repository trees.
- **Stop** - Stops the current repository browsing operation executed when a repository node is expanded. This is useful when the operation takes too long or the server is not responding.
- **Settings** - Allows you to configure the resource table appearance.

Repositories View Contextual Menu Actions

The **Repositories** view contextual menu contains various actions, depending on the selected item. If a repository location is selected, the following management actions are available:

New Repository Location (Ctrl + Alt + N (Command + Alt + N on OS X))

Displays the **Add SVN Repository** dialog box. This dialog box allows you to define a new repository location.

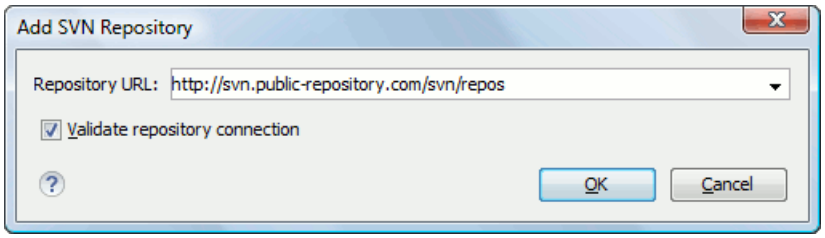

Figure 821: Add SVN Repository Dialog Box

If the **Validate repository connection** option is selected, the URL connection is validated before being added to the **Repositories** view.

Edit Repository Location (Ctrl + Alt + E (Command + Alt + E on OS X))

Context-dependent action that allows you to edit the selected repository location using the **Edit SVN Repository** dialog box. It is active only when a repository location root is selected.

Change the Revision to Browse (Ctrl + Alt + B (Command + Alt + B on OS X))

Context-dependent action that allows you to change the selected repository revision using the **Change the Revision to Browse** dialog box. It is active only when a repository location root is selected.

Remove Repository Location (Ctrl + Alt + R (Command + Alt + R on OS X))

Allows you to remove the selected repository location from the view. It shows you a confirmation dialog box before removal. It is active only when a repository location root is selected.

The following actions are common to all repository resources:

Open

Opens the selected file in the Editor view in read-only mode.

Open with

Displays the **Open with** dialog box to specify the editor in which the selected file is opened. If multiple files are selected, only external applications can be used to open the files.

Save as

Saves the selected files locally, as they are in the browsed revision.

Refresh (F5)

Refreshes the resource selected in the **Repositories** view.

Check out (Ctrl + Alt + O (Command + Alt + O on OS X))

Allows you to create a working copy from a repository directory, on your local file system. To read more about this operation, see the section *Check out a working copy*.

Branch/Tag

Allows you to create a branch or a tag from the selected folder in the repository. To read more about how to create a branch/tag, see the *Creation and management of Branches/Tags* section.

Share project

Allows you to *share a new project* using an SVN repository. The local project is automatically converted into an SVN working copy.

Import:

Import folder (Ctrl + Shift + L (Command + Shift + L on OS X))

Allows you to import the contents of a specified folder from the file system into the selected folder in a repository. To read more about this operation, see the section *Importing resources into a repository*.

Note: The difference between the **Import folder** and **Share project** actions is that the latter also converts the selected directory into a working copy.

Import Files (Ctrl + Shift + I (Command + Shift + I on OS X))

Imports the files selected from the files system into the selected folder in the repository.

Export

Opens *the **Export** dialog box* that allows you to configure options for exporting a folder from the repository to the local file system.

 **Show History (Ctrl + H (Command + T on OS X))**

Displays the history of the selected resource. At the start of the operation, you can set filtering options.

 **Show Annotation (Ctrl + Shift + A (Command + Shift + A on OS X))**

Opens the **Show Annotation** dialog box that computes *the annotations for a file and displays them in the **Annotations** view*, along with the history of the file in the **History** view.

 **Revision Graph (Ctrl + G (Command + G on OS X))**

This action allows you to see the graphical representation of a resource history. For more details about a resource revision graph see *Revision Graph*. This operation is available for any resource selected in the **Repositories** view or **Working Copy** view.

Copy URL Location (Ctrl + Alt + U (Command + Alt + U on OS X))

Copies to clipboard the URL location of the selected resource.

 **Copy to**

Copies to a specified location the currently selected resource(s). This action is also available when you browse other revisions than the latest one (*HEAD*), to allow restoring previous versions of an item.

Move to (Ctrl + M (Command + M on OS X))

Moves to a specified location the currently selected resource(s).

Rename ((F2))

Renames the selected resource.

 **Delete ((Delete))**

Deletes selected items from the repository via an immediate commit.

New Folder (Ctrl + Shift + F (Command + Shift + F on OS X))

Allows you to create a folder in the selected repository path (available only for folders).

Locking

The following options are available only for files:

 **Lock (Ctrl + K (Command + K on OS X))**

Allows you to lock certain files for which you need exclusive access. For more details on the use of this action, see *Locking a file*.

Unlock (Ctrl + Shift + K (Command + Shift + K on OS X))

Releases the exclusive access to a file from the repository. You can also choose to unlock it by force (*break the lock*).

Show SVN Properties (Ctrl + Shift + P (Command + Shift + P on OS X))

Brings up the *Properties view* displaying the SVN properties for the selected resource. This view does not allow adding, editing, or removing SVN properties of a repository resource. These operations are allowed only for working copy resources.

Show SVN Information (Ctrl + I (Command + I on OS X))

Provides additional information for the selected resource. For more details, go to *Obtain information for a resource*.

Assistant Actions

When there is no repository configured, the **Repositories** view mode lists the following two actions:

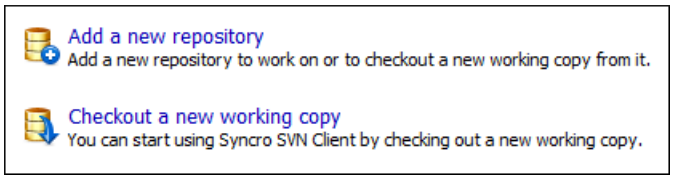

Figure 822: Repositories View Actions

Drag and Drop Operations

The structure of the files tree can be changed with drag and drop operations inside the **Repositories** view. These operations behave in the same way with the **Copy to**/**Move to** operations.

Working Copy View

The **Working Copy** view allows you to manage the content of an SVN working copy. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

The toolbar contains the following:

- The list of defined working copies.
- A set of view modes that allow you to filter the content of the working copy based on the resource status (such as incoming or outgoing changes).
- **Settings** menu.

If you click any of the view modes (**All Files**, **Modified**, **Incoming**, **Outgoing**, **Conflicts**), the information displayed changes as follows:

- **All Files** - Resources (files and folders) are presented in a hierarchical structure with the root of the tree representing the location of the working copy on the file system. Each resource has an icon representation that describes the type of resource and also depicts the state of that resource with a small overlay icon.

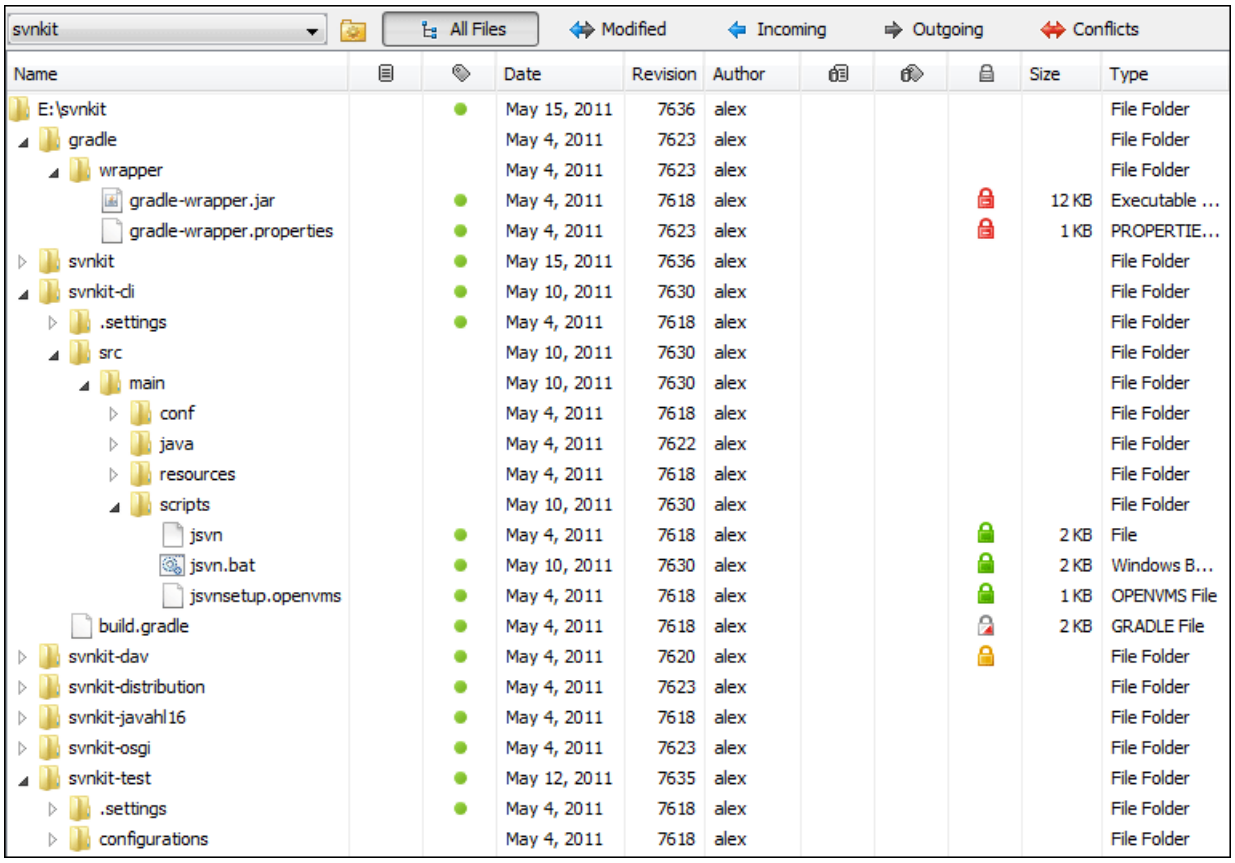

Figure 823: Working Copy View - All Files View Mode

- **Modified** - The resource tree presents resources modified locally (including those with conflicting content) and remotely. Decorator icons are used to differentiate between various resource states:
  - Incoming modification from repository:
    - - File content or properties modified remotely.
    - - New file added remotely.
    - - File deleted remotely.
  - Outgoing modification to repository:
    - - File content or properties modified locally.
    - - New file added locally.
    - - File deleted locally.
- - **Pseudo-conflict state** - A resource being locally and remotely modified at the same time, or a parent directory of such a resource.
- - **Real conflict state** - A resource that had both incoming and outgoing changes and not all the differences could be merged automatically through the update operation (manually editing the local file is necessary for resolving the conflict).

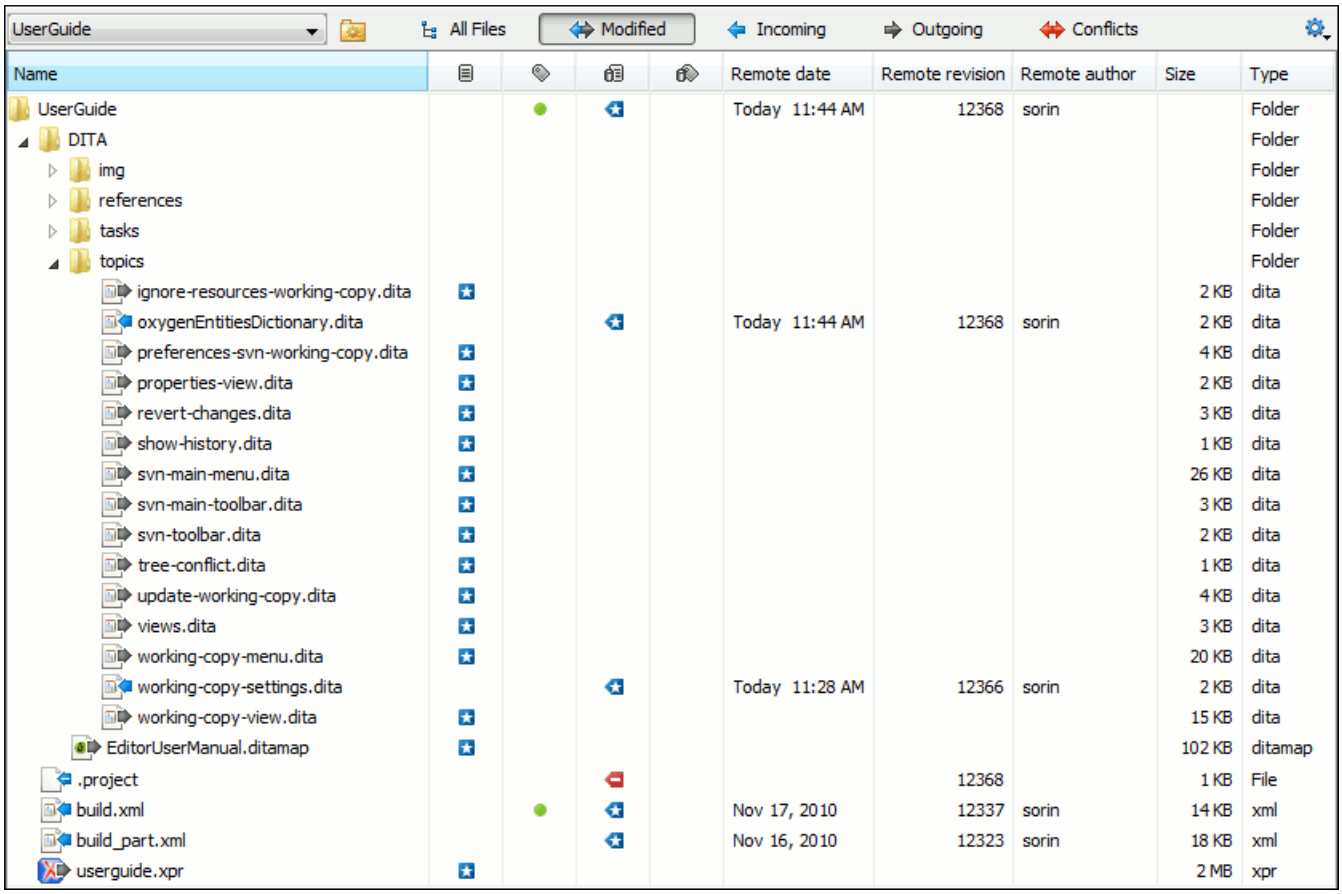

Figure 824: Working Copy View - Modified View Mode

- **Incoming** - The resource tree presents only incoming changes.
- **Outgoing** - The resource tree presents only outgoing changes.
- **Conflicts** - The resource tree presents only conflicting changes (real conflicts and pseudo-conflicts).

The following columns provide information about the resources:

- **Name** - Resource name. Resource icons can have the following decorator icons:
  - Additional status information:
    - **Propagated modification marker** - A folder marked with this icon indicates that the folder itself presents some changes (such as modified properties) or a child resource has been modified.
    - **External** - This indicates a mapping of a local directory to the URL of a versioned resource. It is declared with a `svn:externals` property in the parent folder and it indicates a working copy not directly related with the parent working copy that defines it.
    - **Switched** - This indicates a resource that has been switched from the initial repository location to a new location within the same repository. The resource goes to this state as a result of *the Switch action* executed from the contextual menu of the Working Copy view.
    - **Grayed** - A resource with a grayed-out icon, but no overlaid icon, is an ignored resource. It is obtained with the **Add to svn:ignore** action.
  - Current SVN depth of a folder:
    - **Immediate children (immediates)** (a variant of *sparse checkout*) - The directory contains only direct file and folder children. Child folders ignore their content.
    - **File children only (files)** (a variant of *sparse checkout*) - The directory contains only direct file children, disregarding any child folders.

- **This folder only (empty)** (a variant of *sparse checkout*) - The directory discards any child resource.

Note:

- Any folder not marked with one of the depth icons, has recursive depth (*infinity*) set by default (presents all levels of child resources).
- Although folders not under version control can have no depth set, Oxygen XML Editor presents *unversioned* and *ignored* folders with *empty* depth when **Show unversioned directories content** or **Show ignored directories content** options are not selected.

- **Local file status** - Shows the changes of working copy resources that were not committed to the repository yet. The following icons are used to mark resource status:
  - - Resource is *not under version control* (*unversioned*).
  - - Resource is being *ignored* because it is not under version control and its name matches a file name pattern defined in one of the following places:
    - *global-ignores* section in the SVN client-side *config file*.

      Attention: If you do not explicitly set the `global-ignores` runtime configuration option (either to your preferred set of patterns or to an empty string), Subversion uses the default value.
    - ***Application global ignores** option* of Oxygen XML Editor.
    - The value of a *svn:ignore property* set on the parent folder of the resource being ignored.
  - - Marks a newly created resource, *scheduled for addition* to the version control system.
  - - Marks a resource *scheduled for addition*, created by copying a resource already under version control and inheriting all its SVN history.
  - - The content of the resource has been *modified*.
  - - Resource has been *replaced* in your working copy (the file was scheduled for deletion, and then a new file with the same name was scheduled for addition in its place).
  - - Resource is *deleted* (scheduled for deletion from **Repository** upon the next commit).
  - - The resource is *incomplete* (as a result of an interrupted *check out* or *update* operation).
  - - The resource is *missing* because it was moved or deleted without using an SVN-aware application.
  - - The contents of the resource is in *real conflict state*.
  - - Resource is in a *name conflict* state.
  - - Resource is in *tree conflict* state after an update operation because:
    - Resource was locally modified and incoming deleted from repository.
    - Resource was locally scheduled for deletion and incoming modified.
  - - Resource is *obstructed* (versioned as one kind of object: file, directory, or symbolic link, but has been replaced outside Syncro SVN Client by a different kind of object).
- **Local properties status** - Marks the resources that have SVN properties, with the following possible states:
  - - The resource has SVN properties set.
  - - The resource properties have been modified.
  - - Properties for this resource are in *real conflict* with property updates received from the repository.
- **Revision** - The current revision number of the resource.
- **Date** - Date when the resource was last time modified on the disk.
- **BASE Revision** - The revision number of the pristine version of the resource.
- **BASE Date** - Date when the pristine version of the resource was last time committed in the repository.
- **Author** - Name of the person who made the last modification on the pristine version of the resource.
- **Remote file status** - Shows changes of resources recently modified in the repository. The following icons are used to mark incoming resource status:
  - - Resource is newly added in repository.
  - - The content of the resource has been modified in repository.
  - - Resource was replaced in repository.

- - Resource was deleted from repository.

- **Remote properties status** - Resources marked with the icon have incoming modified properties from the repository.
- **Remote revision** - Revision number of the resource latest committed modification.
- **Remote date** - Date of the resource latest modification committed on the repository.
- **Remote author** - Name of the author who committed the latest modification on the repository.
- **Lock information** - Shows the lock state of a resource. The lock mechanism is a convention intended to help you signal other users that you are working with a particular set of files. It minimizes the time and effort wasted in solving possible conflicts generated by clashing commits. A lock gives you exclusive rights over a file, only if other users follow this convention and they do not try to bypass the lock state of a file.

  A folder can be locked only by the SVN client application, completely transparent to the user, if an operation in progress was interrupted unexpectedly. As a result, folders affected by the operation are marked with the symbol. To clear the locked state of a folder, use the **Clean up** action.

  Note: Users can lock only files.

  The following lock states are displayed:

  - *no lock* - the file is not locked. This is the default state of a file in the SVN repository.
  - *remotely locked* ( ) - shown when:
    - Another user has locked the file in the repository.
    - The file was locked by the same user from another working copy.
    - The file was locked from the **Repositories** view.

    If you try to commit a new revision of the file to the repository, the server does not allow you to bypass the file lock.

    Note: To commit a new revision, you need to wait for the file to be unlocked. Ultimately, you might try to *break* or *steal* the lock, but this is not what other users expect. Use these actions carefully, especially when you are not the file lock owner.
  - *locked* ( ) - displayed after you have locked a file from the current working copy. Now you have exclusive rights over the corresponding file, being the only one who can commit changes to the file in the repository.

    Note: Working copies keep track of their locked files, so the locks are presented between different sessions of the application. Synchronize your working copy with the repository to make sure that the locks are still valid (not *stolen* or *broken*).
  - *stolen* ( ) - a file already locked from your working copy is being locked by another user. Now the owner of the file lock is the user who stole the lock from you.
  - *broken* ( ) - a file already locked from your working copy is no longer locked in the repository (it was unlocked by another user).

    Note: To remove the *stolen* or *broken* states from your working copy files, you have to **Update** them.

  If one of your working copy files is locked, hover the mouse pointer over the lock icon to see more information:

  - Lock type - current file lock state
  - Owner - the name of the user who created the lock
  - Date - the date when the user locked the file
  - Expires on - date when the lock expires. Lock expiry policy is set in the repository options, on the server side
  - Comment - the message attached when the file was locked
- **Size** - Resource size on disk
- **Type** - Contains the resource type or file extension

Note: The working copy table allows you to show or hide any of its columns and also to sort its contents by any of the displayed columns. The table header provides a contextual menu that allows you to customize the displayed information.

The toolbar contains the following options for switching to a different working copy:

- **List of Defined Working Copies** - A drop-down menu that contains all the working copies Oxygen XML Editor is aware of. When you select a different working copy from the list, the newly selected working copy content is scanned and displayed in the **Working Copy** view.
- (on Mac OS X) **Working Copies Manager** - Opens a dialog box that displays the working copies Oxygen XML Editor is aware of. In this dialog box, you can add existing working copies or remove those you no longer need. If you try to add a folder that is not a valid Subversion working copy, Oxygen XML Editor warns you that the selected directory is not under version control.

  Note: Removing a working copy from this dialog box does NOT remove it from your file system; you will have to do that manually.

Working Copy Settings

The **Settings** button from the toolbar of the **Working Copy** view provides the following options:

- **Show unversioned directories content** - Displays the content of unversioned directories.

  Note: If this option is not selected, it will be ignored for items that, after a synchronize, are reported as incoming from the repository. This applies for all working copy modes, except **All Files**.
- **Show ignored items** - Displays the ignored resource when **All Files** mode is selected.
- **Show ignored directories content** - Displays the content of ignored directories when **All Files** mode is selected.

  Note: Although *ignored* items are not presented in the **Modified**, **Incoming**, and **Conflicts** modes, they will be if, after a synchronize, they are reported as incoming from the repository.
- **Show deleted items** - Displays the deleted resource when **All Files** mode is selected. All other modes always display deleted resources, disregarding this option.
- **Tree** / **Compressed** / **Flat** - Affect the way information is displayed inside the **Modified**, **Incoming**, **Outgoing**, and **Conflicts** view modes.
- **Configure columns** - Allows you to customize the structure of the **Working Copy** view data. This action opens the following dialog box:

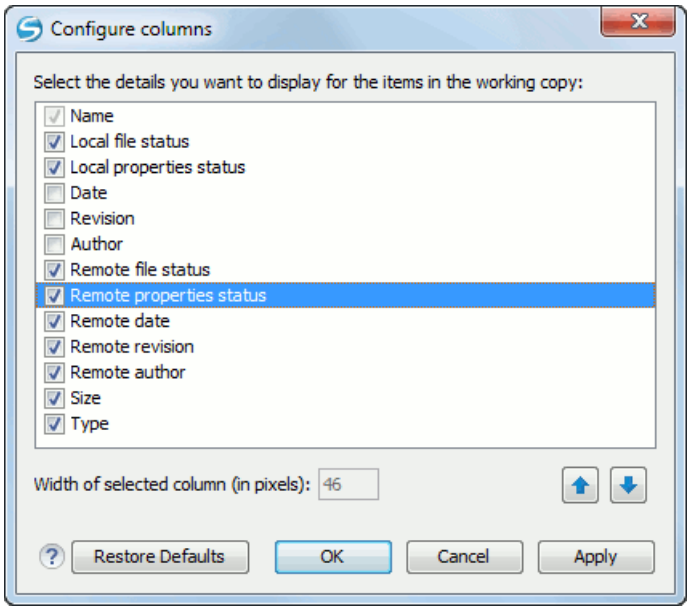

Figure 825: Configure Columns of Working Copy View

The order of the columns can be changed with the two arrow buttons. The column size can be edited in the **Width of selected column** field. The **Restore Defaults** button reverts all columns to the default order, width, and enabled/disabled state from the installation of the application.

Working Copy Format

When an SVN working copy is loaded, Syncro SVN Client first checks the format of the working copy:

- If the format is older than SVN 1.7, you are prompted to upgrade it to SVN 1.8 to load it.
- If the format is 1.7, Syncro SVN Client takes into account the state of the ***When loading an old format working copy****option*.

To change how working copy formats are handled, *open the* ***Preferences*** *dialog box* ***(Options > Preferences)***, go to **SVN** > **Working copy**, and configure the options in the ***Administrative area*** section.

Note:

- The format of the working copy can be downgraded or upgraded at any time with the **Upgrade** and **Downgrade** actions available in the **Tools** menu. These actions allow switching between SVN 1.7 and SVN 1.8 working copy formats.
- SVN 1.7 working copies cannot be downgraded to older formats.

Refresh a Working Copy

A refresh is a frequent operation triggered automatically when you switch between two working copies using the toolbar selector of the **Working Copy** view and when you switch between Oxygen XML Editor and other applications.

The **Working Copy** view features a fast refresh mechanism: the content is cached locally when loading the working copy for the first time. Later on, when the same working copy is displayed again, the application uses this cache to detect the changes between the cached content and the current content found on disk. The refresh operation is run on these changes only, thus improving the response time. improvement is noticeable especially when working with large working copies.

Working Copy View Contextual Menu Actions

The contextual menu in the **Working Copy** view contains the following actions:

Edit conflict (Ctrl (Command on OS X) + E)

Opens the **Compare** editor, allowing you to modify the content of the currently conflicting resources. For more information about editing conflicts, see *Edit conflicts*.

Open in Compare Editor (Ctrl (Command on OS X) + Alt + C)

Displays changes made in the currently selected file.

Open (Ctrl (Command on OS X) + O)

Opens the selected resource from the working copy. Files are opened with an internal editor or an external application associated with that file type, while folders are opened with the default file system browsing application (Windows Explorer on Windows, Finder on OS X, etc).

Open with...

Submenu that allows you to open the selected resource either with Oxygen XML Editor or with another application.

Show in Explorer/Show in Finder

Opens the parent directory of the selected working copy file and selects the file.

 **Expand All (Ctrl (Command on OS X) + Alt + X)**

Displays all descendants of the selected folder. The same behavior is obtained by double-clicking a collapsed folder.

 **Refresh (F5)**

Re-scans the selected resources recursively and refreshes their status in the working copy view.

 **Synchronize (Ctrl (Command on OS X) + Shift + S)**

Connects to the repository and determines the working copy and repository changes made to the selected resources. The application switches to **Modified** view mode if the ***Always switch to 'Modified' mode*** *option* is selected.

Update (Ctrl (Command on OS X)+ U)

Updates the selected resources to the *HEAD* revision (latest modifications) from the repository. If the selection contains a directory, it will be updated depending on its depth.

Update to revision/depth

Allows you to update the selected resources from the working copy to an earlier revision from the repository. You can also select the update *depth* for the current folder. You can find out more about the *depth* term in the *sparse checkouts* section.

Commit

Collects the outgoing changes from the selected resources in the working copy and allows you to choose exactly what resources to commit. A directory will always be committed recursively. Unversioned resources will be deselected by default. In the **Commit** dialog box you can also enter a comment before sending your changes to the repository.

Revert (Ctrl (Command on OS X) + Shift + V)

Undoes all local changes for the selected resources. It does not contact the repository and the files are obtained from Apache Subversion™ pristine copy. It is available only for modified resources. See *Revert your changes* for more information.

Override and Update

Drops any outgoing change and replaces the local resource with the HEAD revision. This action is available on resources with outgoing changes, including conflicting ones. See the *Revert your changes* section.

Override and Commit

Drops any incoming changes and sends your local version of the resource to the repository. This action is available on conflicting resources. For more information see *Drop incoming modifications*.

Mark Resolved (Ctrl (Command on OS X) + Shift + R)

Instructs the Subversion system that you resolved a conflicting resource. For more information, see *Merge conflicts*.

Mark as Merged (Ctrl (Command on OS X) + Shift + M)

Instructs the Subversion system that you resolved the pseudo-conflict by merging the changes and you want to commit the resource. Read the *Merge conflicts* section for more information about how you can solve the pseudo-conflicts.

Create patch (Ctrl (Command on OS X) + Alt + P)

Allows you to create a file containing all the differences between two resources, based on the `svn diff` command. To read more about creating patches, see *the section about patches*.

Compare with:

- **Latest from HEAD (Ctrl (Command on OS X) + Alt + H)** - Performs a 3-way diff operation between the selected file and the *HEAD* revision from the repository and displays the result in the **Compare view**. The common ancestor of the 3-way diff operation is the *BASE* version of the file from the local working copy.
- **BASE revision (Ctrl (Command on OS X) + Alt + C)** - Compares the working copy file with the BASE revision file (the so-called *pristine copy*).
- **Revision (Ctrl (Command on OS X) + Alt + R)** - Displays the **History view** that contains the log history of that resource.
- **Branch/Tag** - Opens the **Compare with Branch/Tag** dialog box that allows you to specify *another file from the repository* (**To URL** field) to compare with the working copy file. You can specify the revision of the repository file by choosing between **HEAD revision** or specific **Other revision**.

  Tip: To compare with a file that was deleted, moved, or replaced, you need to specify the original URL (before the file was removed) and use a *peg revision* at the end (for example, URL`@rev1234`).
- **Each other** - Compares two selected files with each other.

These *compare* actions are available only if the selected resource is a file.

Replace with:

- **Latest from HEAD** - Replaces the selected resources with their versions from the *HEAD* revision of the repository.
- **BASE revision** - Replace the selected resources with their versions from the pristine copy (the BASE revision).

Note: In some cases it is impossible to replace the currently selected resources with their versions from the *BASE/HEAD* revision:

- For the **Replace with BASE revision** action, the resources being unversioned or added have no *BASE* revision, and thus cannot be replaced. However, they will be deleted if the action is invoked on a parent folder. The action will never work for missing folders or for obstructing files (folders being obstructed by a file), since you cannot recover a tree of folders
- For the **Replace with latest from HEAD** action, you must be aware that there are cases when resources will be completely deleted or reverted to the BASE revision and then updated to a HEAD revision to avoid conflicts. These cases are:
  - The resource is *unversioned*, *added*, *obstructed*, or *modified*.
  - The resource is affected by a `svn:ignore` or `svn:externals` property that is locally added on the parent folder and not yet committed to the repository.

Show History (Ctrl (Command on OS X) + H)

Displays the **History view** where the log history for the selected resource will be presented. For more details about resource history, see the sections about *the resource history view* and *requesting the history for a resource*.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on OS X))

Opens the **Show Annotation** dialog box that computes *the annotations for a file and displays them in the **Annotations** view*, along with the history of the file in the **History** view.

Revision Graph (Ctrl (Command on OS X) + G)

This action allows you to see the graphical representation history of a resource. For more details about the revision graph of resources, see *Revision Graph*.

Copy URL Location (Ctrl (Command on OS X) + Alt + U)

Copies the encoded URL of the selected resource from the Working Copy to the clipboard.

Mark as copied

You can use this action to mark an item from the working copy as a copy of an other item under *version control*, when the copy operation was performed outside of an SVN client. The **Mark as copied** action is available when you select two items (both the new item and source item), and it depends on the state of the source item.

Mark as moved

You can use this action to mark an item from the working copy as being moved from another location of the working copy, when the move operation was performed outside of an SVN client. The **Mark as moved** action is available when you select two items from different locations (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Mark as renamed

You can use this action to mark an item from the working copy as being renamed outside of an SVN client. The **Mark as renamed** action is available when you select two items from the same directory (both the new item and the source item that is usually reported as *missing*), and it depends on the state of the source item.

Copy to

Copies the currently selected resource to a specified location.

Move to Ctrl + M (Command + M on OS X)

Moves the currently selected resource to a specified location.

Rename (F2)

As with the move command, a copy of the original resource will be made with the new name and the original will be marked as deleted. Note that you can only rename one resource at a time.

Delete (Delete)

Schedules selected items for deletion upon the next commit and removes them from the disk. Depending on the state of each item, you are prompted to confirm the operation.

New:

- **New File** - Creates a new file inside the selected folder. The newly created file will be added under version control only if the parent folder is already versioned.
- **New Folder (Ctrl (Command on OS X)+ Shift + F)** - Creates a child folder inside the selected folder. The newly created folder will be added under version control only if its parent is already versioned.
- **New External Folder (Ctrl (Command on OS X) + Shift + W)** - This operation allows you to add a new external definition on the selected folder. An external definition is a mapping of a local directory to *a URL of a versioned directory*, and ideally a particular revision, stored in the `svn:externals` property of the selected folder.

  Tip: You can specify a particular revision of the external item by using a *peg revision* at the end of the URL (for example, URL`@rev1234`). You can also use peg revisions to access external items that were deleted, moved, or replaced.

  The URL used in the external definition format can be relative. You can specify the repository URL that the external folder points to by using one of the following relative formats:

  - **../** - Relative to the URL of the directory that the `svn:externals` property is set.
  - **^/** - Relative to the root of the repository in which the `svn:externals` property is versioned.
  - **//** - Relative to the scheme of the URL of the directory that the `svn:externals` property is set.
  - **/** - Relative to the root URL of the server in which the `svn:externals` property is versioned.

  Important: To change the target URL of an external definition, or to delete an external item, do the following:

  1. Modify or delete the item definition found in the `svn:externals` property that is set on the parent folder.
  2. For the change to take effect, use the **Update** operation on the parent folder of the external item.

  Note: Syncro SVN Client does not support definitions of local relative external items.

Add to "svn:ignore" (Ctrl (Command on OS X) + Alt + I)

Allows you to add files that should not participate in the *version control* operations inside your working copy . This action can only be performed on resources not under *version control*. It actually modifies the value of the `svn:ignore` property in the parent directory of the resource. Read more about this in the *Ignore Resources Not Under Version Control* section.

Add to version control (Ctrl (Command on OS X) + Alt + V)

Allows you to add resources that are not under *version control*. For further details, see *Add Resources to Version Control* section.

Remove from version control

Schedules selected items for deletion from repository upon the next commit. The items are not removed from the file system after committing.

Clean up (Ctrl (Command on OS X) + Shift + C)

Performs a maintenance cleanup operation on the selected resources from the working copy. This operation removes the Subversion maintenance locks that were left behind. This is useful when you already know where the problem originated and want to fix it as quickly as possible. It is only active for resources under *version control*.

Locking:

- **Scan for locks (Ctrl (Command on OS X) + L)** - Contacts the repository and recursively obtains the list of locks for the selected resources. A dialog box containing the locked files and the lock description will be displayed. This is only active for resources under *version control*. For more details see *Scanning for locks*.
- **Lock (Ctrl (Command on OS X) + K)** - Allows you to lock certain files that need exclusive access. You can write a comment describing the reason for the lock and you can also force (*steal*) the lock. This action is active only on files under *version control*. For more details on the use of this action see *Locking a file*.

- **Unlock (Ctrl (Command on OS X) + Alt + K)** - Releases the exclusive access to a file from the repository. You can also choose to unlock it by force (*break the lock*).

Show SVN Properties (Ctrl + P (Command + P on OS X))

Brings up the *Properties view* and displays the SVN properties for the selected resource.

Show SVN Information (Ctrl + I (Command + I on OS X))

Provides additional information for the selected resource from the working copy. For more details, go to *Obtain information for a resource*.

Drag and Drop Operations

The structure of the files tree can be changed with drag and drop operations inside the **Working Copy** view. These operations behave in the same way with the **Copy to**/**Move to** operations.

Also, files and folders can be added to the file tree of the view as *unversioned* resources by drag and drop operations from other applications (for example, from Windows Explorer or Mac OS X Finder). In this case, the items from the file system are only copied, without removing them from their original location.

Attention: When you drag items from the working copy to a different application, the performed operation is controlled by that application. This means that the moved items are left as *missing* in the working copy (items are moved in the file system only, but no SVN versioning meta-data is changed).

Assistant Actions

To ensure a continuous and productive work flow, when a view mode has no files to present, it offers a set of guiding actions with some possible paths to follow.

Initially, when there is no working copy configured the **All Files** view mode lists the following two actions:

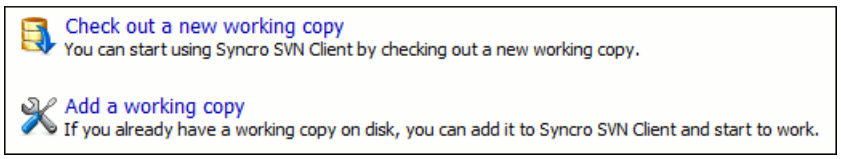

Figure 826: All Files Panel

For **Modified**, **Incoming**, **Outgoing**, **Conflicts** view modes, the following actions may be available, depending on the current working copy state in various contexts:

- **Synchronize with Repository** - Available only when there is nothing to present in the **Modified** and **Incoming** view modes.
- **Switch to Incoming** - Selects the **Incoming** view mode.
- **Switch to Outgoing** - Selects the **Outgoing** view mode.
- **Switch to Conflicts** - Selects the **Conflicts** view mode.
- **Show all changes/incoming/outgoing/conflicts** - Depending on the currently selected view mode, this action presents the corresponding resources after a synchronize operation was executed only on a part of the working copy resources.
- **(Information message)** - Informs you why there are no resources presented in the currently selected view mode.

History View

In Apache Subversion™, both files and directories are versioned and have a history. If you want to examine the history for a selected resource and find out what happened at a certain revision you can use the **History view** that can be accessed from *Repositories view*, *Working Copy view*, *Revision Graph*, or *Directory Change Set view*. From

the **Working copy view** you can display the history of local versioned resources. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

The view consists of four distinct areas:

- The table showing details about each revision, such as revision number, commit date and time, number of changes (more details available in the tooltip), author's name, and a fragment of the commit message.

  Some revisions may be highlighted to emphasize:

  - The current revision of the resource for which the history is displayed - a bold font revision.
  - The last revision in which the content or properties of the resource were modified - blue font revision.

  Note: Both font highlights may be applied for the same revision.
- The complete commit message for the selected revision.
- A tree structure showing the folders where the modified resources are located. You can compress this structure to a more compact form that focuses on the folders that contain the actual modifications.
- The list of resources modified in the selected revision. For each resource, the type of action done against it is marked with one of the following symbols:

  - - A newly created resource.
  - - A newly created resource, copied from another repository location.
  - - The content/properties of the resource were *modified*.
  - - Resource was *replaced* in the repository.
  - - Resource was deleted from the repository.

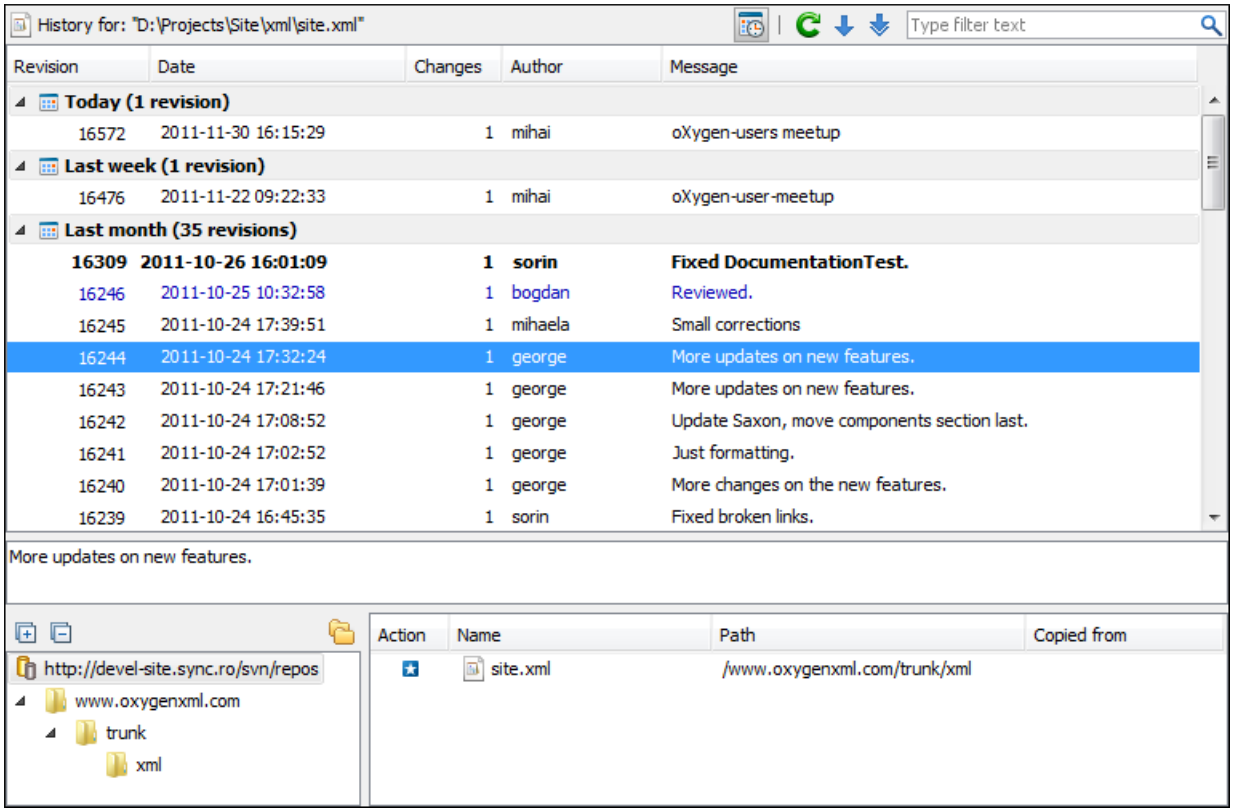

Figure 827: History View

You can group revisions in predefined time frames (today, yesterday, this week, this month), by pressing the **Group by date** button from the toolbar.

History Filter Dialog Box

The **History view** does not always show all the changes ever made to a resource because there may be thousands of changes and retrieving the entire list can take a long time. Normally you are interested in the more

recent ones. That is why you can specify the criteria for the revisions displayed in the **History view** by selecting one of several options presented in the **History** dialog box that is displayed when you invoke the **Show History** action.

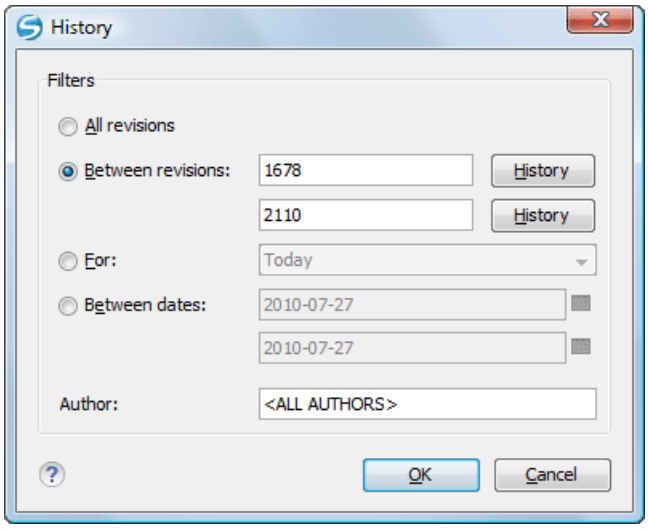

Figure 828: History Filters Dialog Box

Options for the set of revisions presented in the History view are:

- All revisions of the selected resource.
- Only revisions between a start revision number and an end revision number.
- Only revisions added in a period of time (such as today, last week, last month, etc.)
- Only revisions between a start and an end date.
- Only revisions committed by a specified SVN user.

The toolbar of the **History view** has two buttons for extending the set of revisions presented in the view: **Get next 50** and **Get all**.

History Filter Field

When only the history entries that contain a specified substring need to be displayed in the **History** view, the filter field displayed at the top of this view is a useful tool. Just enter the search string in the field next to the **Find** label. Only the items (with an author name, commit message, revision number, or date) that match the search string are kept in the **History** view. When you press the **Search** button, the filter action is executed and the content of the table is updated.

History View Contextual Menu Actions

The **History** view contains the following contextual menu actions:

Compare with working copy

Compares the selected revision with your working copy file. It is available only when you select a file.

Open

Opens the selected revision of the file into the Editor. This is available only for files.

Open with

Displays the **Open with** dialog box to specify the editor in which the selected file will be opened.

Get Contents

Replaces the current version from the working copy with the contents of the selected revision from the history of the file. The *BASE* version of the file is not changed in the working copy so that after this action the file will appear as modified in a synchronization operation, that is newer than the *BASE* version, even if the contents is from an older version from history.

Save as

Allows you to save the contents of a file as it was committed at a certain revision. This option is available only when you access the history of a file.

Copy to

Copies to the repository the item whose history is displayed, using the selected revision. This option is active only when presenting the history for a repository item (URL).

Note: This action can be used to resurrect deleted items also.

Revert changes from this revision

Reverts changes that were made in the selected revisions. The changes are reverted only in your working copy and does not affect the repository items. It does not replace your working copy items with those from the selected revisions. This action is available when the resource history was launched for a local working copy resource.

Note: For items displayed in the **Affected Paths** section that were *added*, *deleted*, or *replaced*, this action has no effect because such changes are considered to be changes to the parent directory. To revert these type of changes, follow these steps:

1. Request the history for the parent directory.
2. Identify the revision that contains the changes you want to revert.
3. Invoke the action on that revision.

Warning: There are instances where the SVN Client is not able to identify the corresponding working copy item for the selected item in the **Affected Paths** section. In this case, the action does not proceed and an error message is displayed. For example, the selected item in the **Affected Paths** section is from a different repository location than the working copy item for which the history is displayed.

Update to revision

Updates your working copy resource to the selected revision. This is useful if you want your working copy to reflect a time in the past. It is best to update a whole directory in your working copy, not just one file. Otherwise, your working copy is inconsistent and you are unable to commit your changes.

Check out

Checks out a new working copy of the directory for which the history is presented, from the selected revision.

Export

Opens *the **Export** dialog box* that allows you to configure options for exporting a folder from the repository to the local file system.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on OS X))

Opens the **Show Annotation** dialog box that computes *the annotations for a file and displays them in the **Annotations** view*, along with the history of the file in the **History** view.

Change

Allows you to change commit data for a file:

- *Author* - Changes the name of the SVN user that committed the selected revision.
- *Message* - Changes the commit message of the selected revision.

When two resources are selected in the **History** view, the contextual menu contains the following actions:

Compare revisions

When the resource is a file, the action compares the two selected revisions using the **Compare** view. When the resource is a folder, the action displays the set of all resources from that folder that were changed between the two revision numbers.

Revert changes from these revisions

Similar to the `svn merge` command, it merges two selected revisions into the working copy resource. This action is only available when the resource history was requested for a working copy item.

For more information about the **History view** and its features, see the *Request history for a resource* and *Using the resource history view* sections.

Directory Change Set View

The result of comparing two reference revisions from the history of a folder resource is a set with all the resources changed between the two revision numbers. The changed resources can be contained in the folder or in a subfolder of that folder. These resources are presented in a tree format. For each changed resource all the revisions committed between the two reference revision numbers are presented.

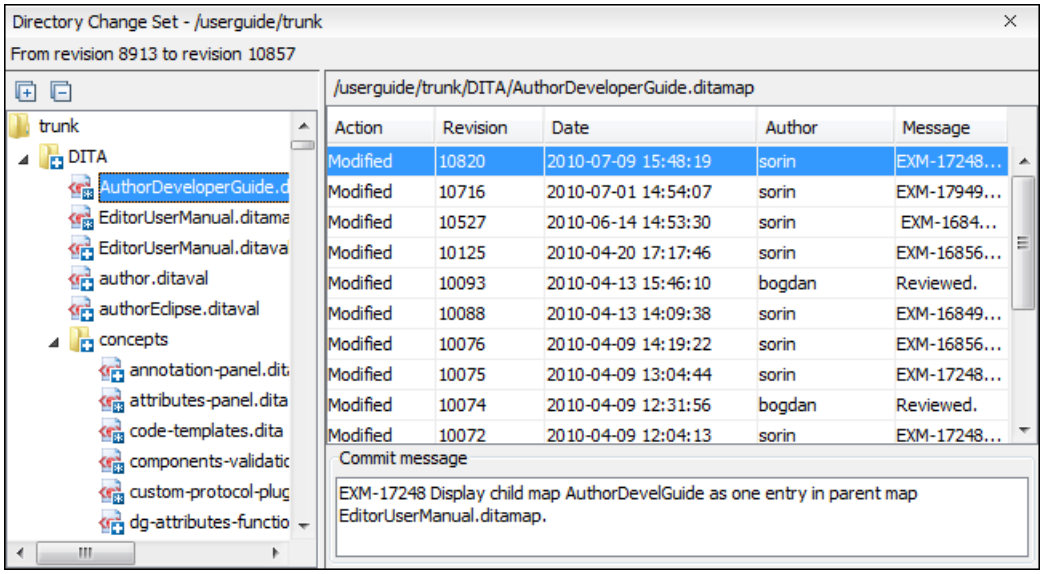

Figure 829: Directory Change Set View

The set of changed resources displayed in the tree is obtained by running the action **Compare revisions** available on the contextual menu of the **History** view when two revisions of a folder resource are selected in the **History** view.

The left side panel of the view contains the tree hierarchy with the names of all the changed resources between the two reference revision numbers. The right side panel presents the list with all the revisions of the resource selected in the left side tree. These revisions were committed between the two reference revision numbers. Selecting one revision in the list displays the commit message of that revision in the bottom area of the right side panel.

Double-clicking a file listed in the left-side tree performs a diff operation between the two revisions of the file corresponding to the two reference revisions. Double-clicking one of the revisions displayed in the right side list of the view performs a diff operation between that revision and the previous one of the same file.

The contextual menu of the right side list contains the following actions:

Compare with previous version

Performs a diff operation between the selected revision in the list and the previous one.

Open

Opens the selected revision in the associated editor type.

Open with

Displays a dialog box with the available editor types and allows you to select the editor type for opening the selected revision.

Save as

Saves the selected file as it was in the selected revision.

Copy to

Copies to the repository the item whose history is displayed, using the selected revision.

Note: This action can be used to resurrect deleted items also.

Check out

Checks out a new working copy of the selected directory, from the selected revision.

Export

Opens *the **Export** dialog box* that allows you to configure options for exporting a folder from the repository to the local file system.

Show Annotation (Ctrl + Shift + A (Command + Shift + A on OS X))

Opens the **Show Annotation** dialog box that computes *the annotations for a file and displays them in the **Annotations** view*, along with the history of the file in the **History** view.

Show SVN Information (Ctrl (Command on OS X) + I)

Provides additional information for a selected resource. For more details, go to *Obtain information for a resource*.

Editor Panel of SVN Client

You can open a file for editing in an internal built-in editor. There are default associations between frequently used file types and the internal editors in *the File Types preferences panel*.

The internal editor can be accessed either from the *Working copy view* or from the *History view*. No actions that modify the content are allowed when the editor is opened with a revision from history.

Only one file at a time can be edited in an internal editor. If you try to open another file it will be opened in the same editor window. The editor provides syntax highlighting for known file types. This means that a different color will be used for each recognized token type found in the file. If the file's content type is unknown you will be prompted to choose the proper way the file should be opened.

After editing the content of the file in an internal editor you can save it to disk by using the **Save** action from the *File* menu or the **Ctrl + S (Command + S on OS X)** key shortcut. After saving your file you can see the file changed status in *the **Working Copy** view*.

If the internal editor associated with a file type is not the XML Editor, then the encoding set in *the preferences for Encoding for non XML files* is used for opening and saving a file of that type. This is necessary because in the case of XML files, the encoding is usually declared at the beginning of the XML file in a special declaration or it assumes the default value UTF-8, but in the case of non-XML files, there is no standard mechanism for declaring the encoding for the file.

Annotations View

Sometimes you need to know not only what was changed in a file, but also who made those changes. The **Annotations** view displays the revision and the author that changed every line in a file. The annotations of a file are computed and this view is opened with the **Show Annotation** action, which is available in the **History** menu, and from the contextual menu of the following views: *the **Repositories** view*, ***Working copy** view*, ***History** view*, and ***Directory Change Set** view*..

This action opens a dialog box that allows you to configure some options for showing the annotations.

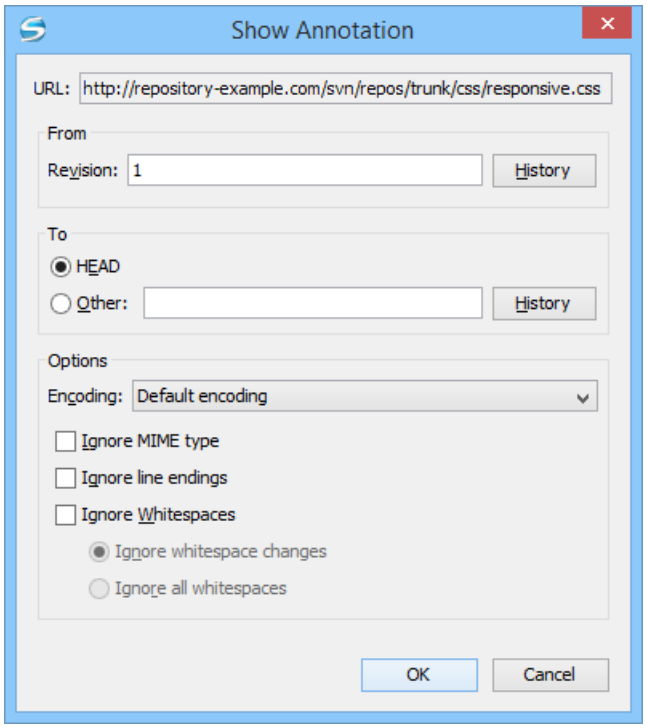

Figure 830: Show Annotation Options Dialog Box

Once you have configured the options and click **OK**, the **Annotations** view is displayed (by default, on the right side of the application). You can click a line in the editor panel where the file is opened to see the revision in which the line was last modified. The same revision is highlighted in the **History view** and you can also see all the lines that were changed in the same revision highlighted in the editor panel. Also, the entries of the **Annotations view** corresponding to that revision are highlighted. Therefore, the **Annotations view**, **History view**, and annotations editor panel are all synchronized. Clicking a line in one of them highlights the corresponding lines in the other two.

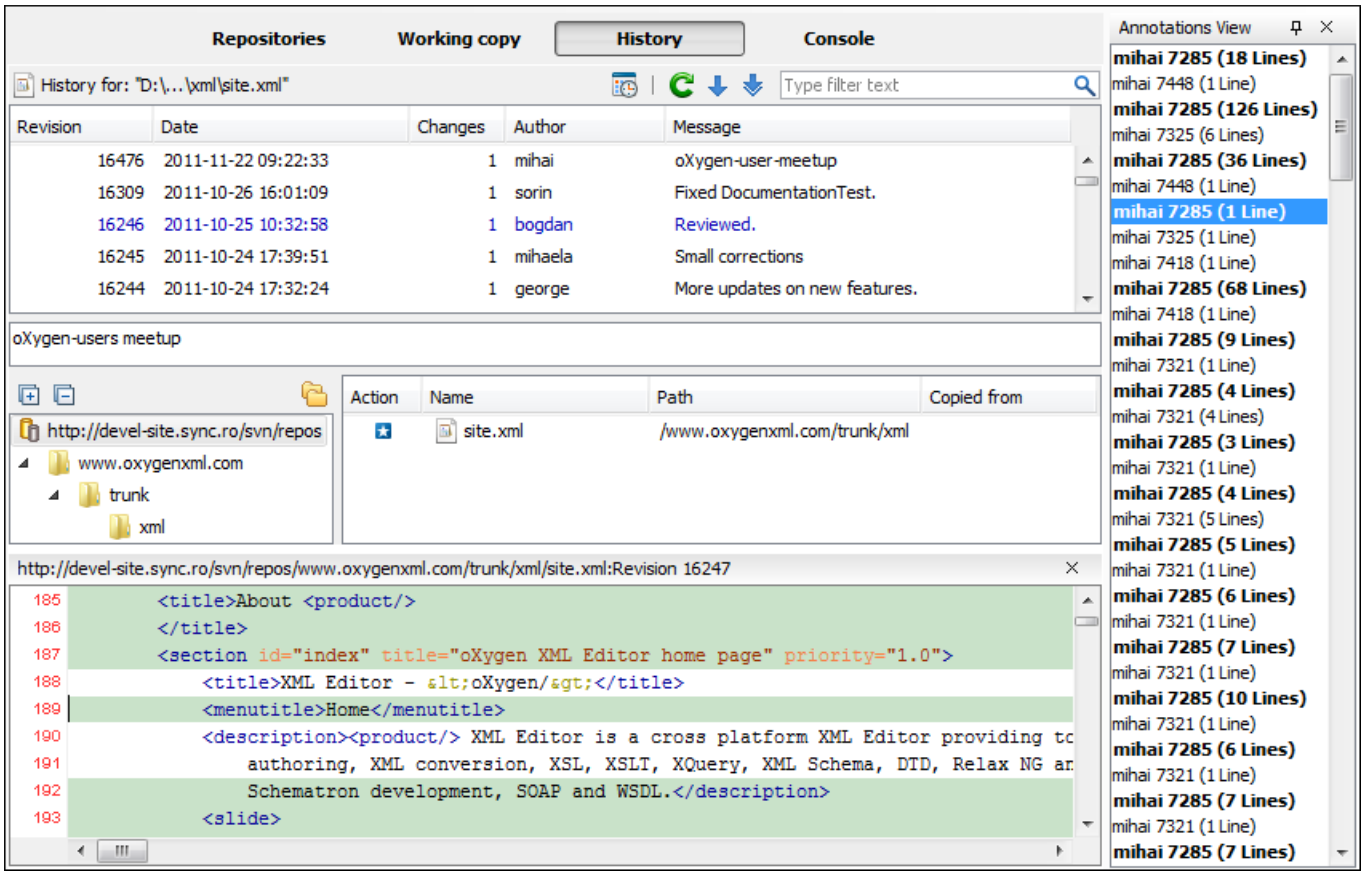

Figure 831: Annotations View

The following options can be configured in the **Show Annotation** dialog box:

From Revision Section

Select the revision from which to start computing the annotation. If you press the **History** button, *the **History** dialog box* is displayed, which allows you to select a revision.

To Revision Section

Select the ending revision by choosing between the **HEAD** revision or specify it in the **Other** text box . If you press the **History** button, *the **History** dialog box* is displayed, which allows you to select a revision.

Encoding

Select the encoding to be used when the annotation is computed. For each line of text, the SVN Client looks through the history of the file to be annotated see when it was last modified, and by whom. It is required that it is in the form of a text file. Therefore, encoding is needed to properly decode and read the file content. By default, the encoding of the operating system is used.

Ignore MIME type

If selected, the file is treated as a text file and ignores what the SVN system infers from the `svn:mime-type` property.

Ignore line endings

If selected, the differences in line endings are ignored when the annotation is computed.

Ignore whitespaces

If selected, it allows you to specify how the whitespace changes should be handled. When selected, you can then choose between two options:

- **Ignore whitespace changes** - Ignores changes in the amount of whitespaces or to their type (for example, when changing the indentation or changing tabs to spaces).

  Note: Whitespaces that were added where there were none before, or that were removed, are still considered to be changes.

- **Ignore all whitespaces** - Ignores all types of whitespace changes.

Tip: Selecting any of these *ignore* options can help you better determine the last time a meaningful change was made to a given line of text.

After you configure the options and press **OK**, the annotations will be computed and the **Annotations** view is displayed, where all the users that modified the selected resource will be presented, along with the specific lines and revision numbers modified by each user.

Note: If the file has a very long history, the computation of the annotation data can take a long time to process.

Compare View

In the Oxygen XML Editor, there are three types of files that can be checked for differences: text files, image files and binary files. For the text files and image files you can use the built-in **Compare** view. This view is automatically opened if you select two files and use the **Compare with** > **Each Other** action in the contextual menu.

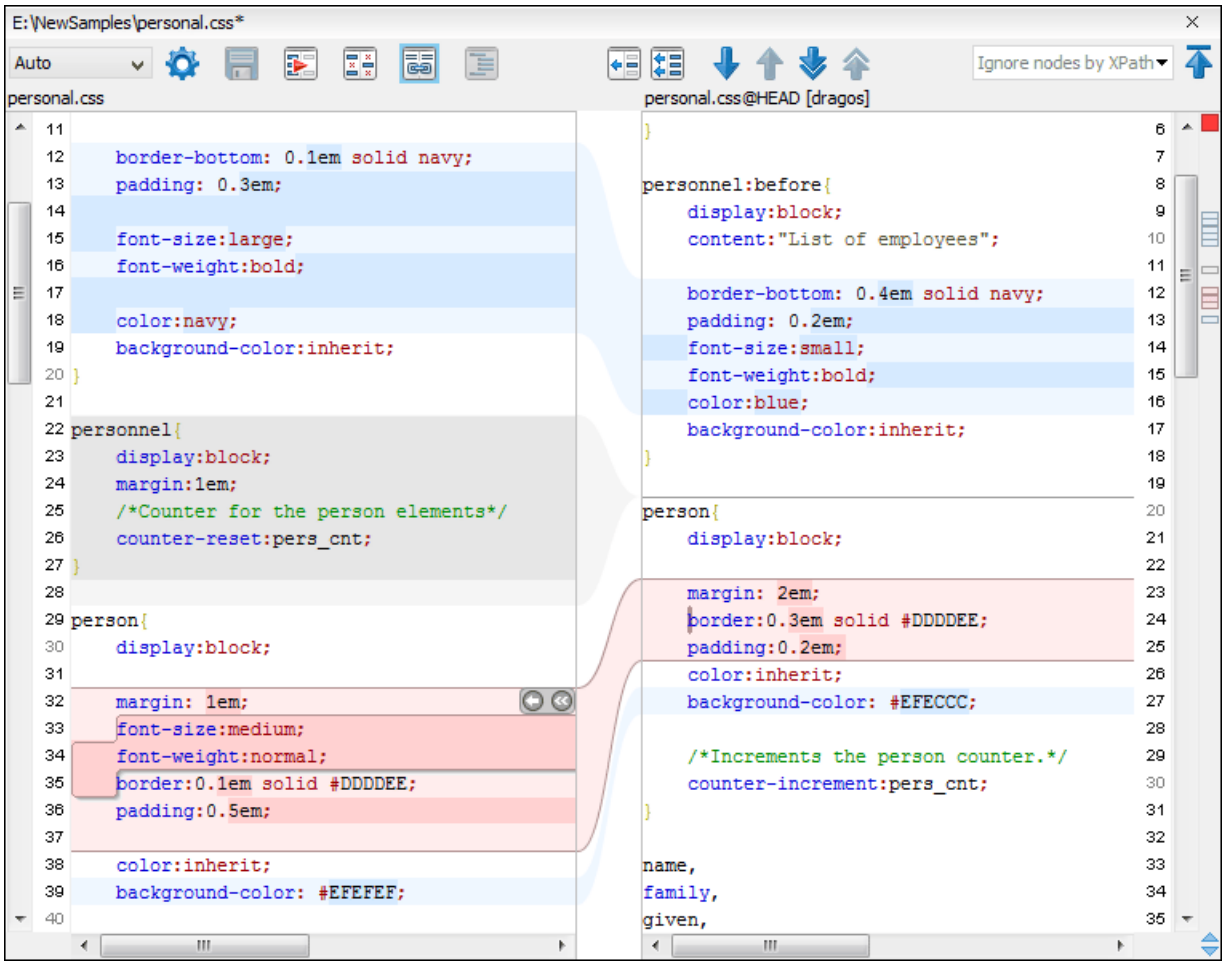

Figure 832: Compare View

At the top of each of the two editors, there are presented the name of the opened file, the corresponding SVN revision number (for remote resources) and the author who committed the associated revision.

When comparing text, the differences are computed using a *line differencing algorithm*. The view can be used to show the differences between two files in the following cases:

- After obtaining the outgoing status of a file with a **Refresh** operation, the view can be used to show the differences between your working file and the pristine copy. In this way you can find out what changes you will be committing.
- After obtaining the incoming and outgoing status of the file with the **Synchronize** operation, you can examine the exact differences between your local file and the *HEAD* revision file.

- You can use the **Compare view** from the **History view** to compare the local file and a selected revision or compare two revisions of the same file.

The Compare view contains two editors. Edits are allowed only in the left editor and only when it contains the working copy file. To learn more about how the view can be used, see *View Differences*.

Compare View Toolbar

The toolbar of the **Compare** view contains the operations that can be performed on the source and target files.

Figure 833: Compare View Toolbar

The following actions are available:

Algorithm

The algorithm to be used for performing a comparison. The following options are available:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Save action

Saves the content of the left editor when it can be edited.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces.

Synchronized scrolling

Toggles synchronized scrolling. When toggled on, a selected difference can be seen in both panels.

Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on OS X))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

Note: When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Ignore Nodes by XPath

You can use this text field to enter an *XPath expression* to ignore certain nodes from the comparison. It will be processed as XPath version 2.0. You can also enter the name of the node to ignore all nodes with the specified name (for example, if you want to ignore all ID attributes from the document, you could simply enter `@id`). This field is only available when comparing XML documents using the **XML Fast** or **XML Accurate** algorithms.

Note: If an XPath expression is specified in the ***Ignore nodes by XPath*** *option* in the **Diff / File Comparison** preferences page, that one is used as a default when the application is started. If you then enter an expression in this field on the toolbar, this one will be used instead of the default. If you delete the expression from this field, neither will be used.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Most of these actions are also available from the *Compare* menu.

Image Preview

You can view your local files by using the built-in **Image Preview** component. The view can be accessed from the *Working copy view* or from the *Repository view*. It can also be used from the *History view* to view a selected revision of a image file.

Only one image file can be opened at a time. If an image file is opened in the *Image preview* and you try to open another one it will be opened in the same window. Supported image types are *GIF*, *JPEG/JPG*, *PNG*, *BMP*. Once the image is displayed in the **Image Preview** panel using the actions from the contextual menu, you can scale the image at its original size (**1:1** action) or scale it down to fit in the view's available area (**Scale to fit** action).

Compare Images View

The images are compared using the **Compare Images** view. This view is automatically opened if you select two image files and use the **Compare with** > **Each Other** action in the contextual menu. The images are presented in the left and right part of the view, scaled to fit the available area. You can use the contextual menu actions to scale the images at their original size or scale them down to fit the view's available area.

The supported image types are: *GIF*, *JPG / JPEG*, *PNG*, *BMP*.

Properties View

The properties view presents Apache Subversion™ properties for the currently selected resource from either the **Working Copy** view or the **Repositories** view. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

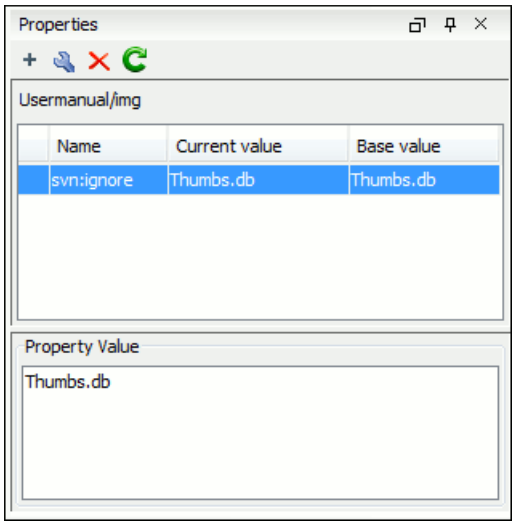

Figure 834: Properties View

The table includes four columns:

- **State** - Can be one of the following:
  - *(empty)* - Normal unmodified property (same current and base values)
  - ** (asterisk)* - Modified property (current and base values are different)
  - *+ (plus sign)* - New property
  - *- (minus sign)* - Removed property
- **Name** - The property name.
- **Current value** - The current value of the property.
- **Base value** - The base (original) value of the property.

`svn:externals` Property

The `svn:externals` property can be set on a folder or a file. In the first case it stores *the URL of a folder from other repository*.

In the second case it stores the URL of a file from other repository. The external file will be added into the working copy as a versioned item. There are a few differences between directory and file externals:

- The path to the file external must be in a working copy that is already checked out. While directory externals can place the external directory at any depth and it will create any intermediate directories, file externals must be placed into a working copy that is already checked out.
- The external file URL must be in the same repository as the URL that the file external will be inserted into; inter-repository file externals are not supported.
- While commits do not descend into a directory external, a commit in a directory containing a file external will commit any modifications to the file external.

The differences between a normal versioned file and a file external:

- File externals cannot be moved or deleted; the `svn:externals` property must be modified instead; however, file externals can be copied.

A file external is displayed as a X in the switched status column.

Toolbar / Contextual Menu

The properties view toolbar and contextual menu contain the following actions:

- **Add a new property** - This button invokes the *Add property* dialog box in which you can specify the property name and value.
- **Edit property** - This button invokes the *Edit property* dialog box in which you can change the property value and also see its original(base) value.

- **Remove property** - This button will prompt a dialog box to confirm the property deletion. You can also specify if you want to remove the property recursively.
- **Refresh** - This action will refresh the properties for the current resource.

Console View

The **Console View** shows the traces of all the actions performed by the application. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Part of the displayed messages mirror the communication between the application and the Apache Subversion™ server. The output is expressed as subcommands to the Subversion server and simulates the Subversion command-line notation. For a detailed description of the Subversion console output read the **SVN User Manual**.

The view has a simple layout, with most of its space occupied by a message area. On its right side, there is a toolbar holding the following buttons:

Clear

Erases all the displayed messages.

Lock scroll

Disables the automatic scrolling when new messages are appended in the view.

The maximum number of lines displayed in the console (length of the buffer) can be modified in the *Preferences* page. By default, this value is set to 100.

Dynamic Help View

Dynamic Help view is a help window that changes its content to display the help section that is specific to the currently selected view. As you change the focused view, you can read a short description of it and its functionality. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Revision Graph of a SVN Resource

The history of a SVN resource can be watched on a graphical representation of all the revisions of that resource together with the tags in which the resource was included. The graphical representation is identical to a tree structure and very easy to follow.

The graphical representation of a resource history is invoked with the **Revision graph** action available on the right-click menu of a SVN resource in *the Working Copy view* and *the Repository view*.

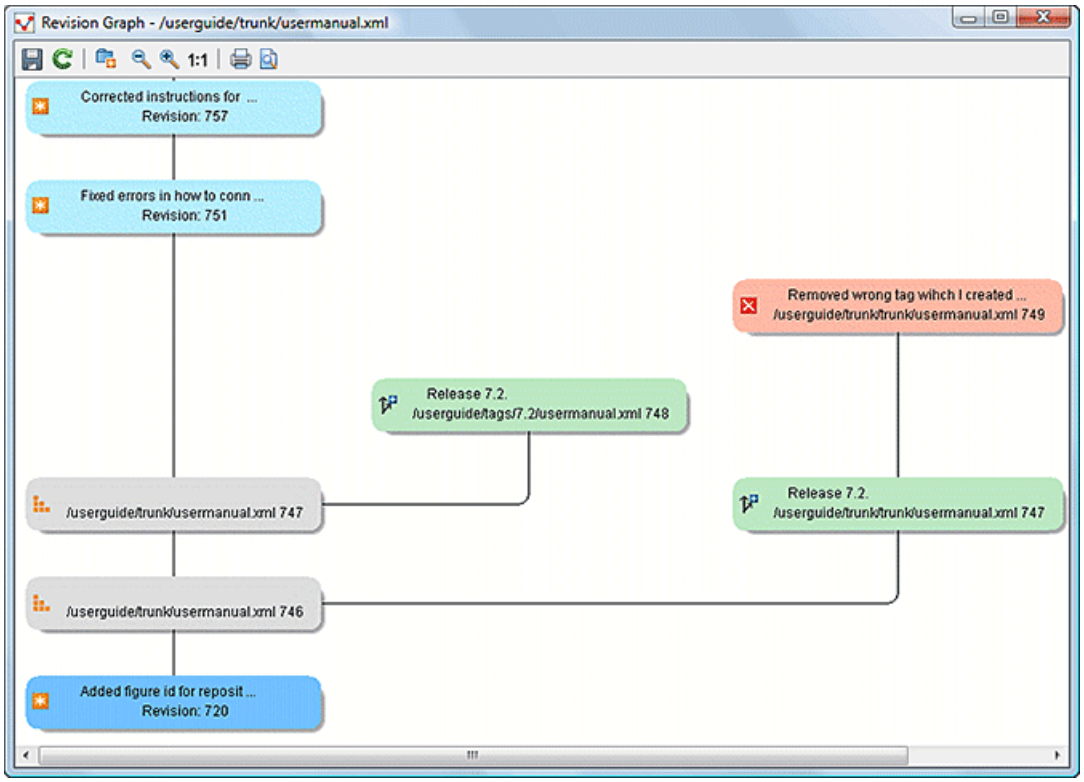

Figure 835: Revision Graph of a File Resource

In every node of the revision graph an icon and the background color represent the type of operation that created the revision represented in that node. The commit message associated with that revision, the repository path, and the revision number are also contained in the node. The tooltip displayed when the mouse pointer hovers over a node specifies the URL of the resource, the SVN user who created the revision of that node, the revision number, the date of creation, the commit message, the modification type and *the affected paths*.

The types of nodes used in the graph are:

Added resource

The icon for a new resource added to the repository and a green background.

Copied resource

The icon for a resource copied to other location (for example, when a SVN tag is created and a green background).

Modified resource

The icon for a modified resource and a blue background.

Deleted resource

The icon for a resource deleted from the repository and a red background.

Replaced resource

The icon for a resource removed and replaced with another one on the repository and a orange background.

Indirect resource

The icon for a revision from where the resource was copied or an indirectly modified resource, that is a directory in which a resource was modified and a gray background. The *Modification type* field of the tooltip specifies how that revision was obtained in the history of the resource.

A directory resource is represented with two types of graphs:

Simplified graph

Lists only the changes applied directly to the directory;

Complete graph

Lists also the indirect changes of the directory resource, that is the changes applied to the resources contained in the directory.

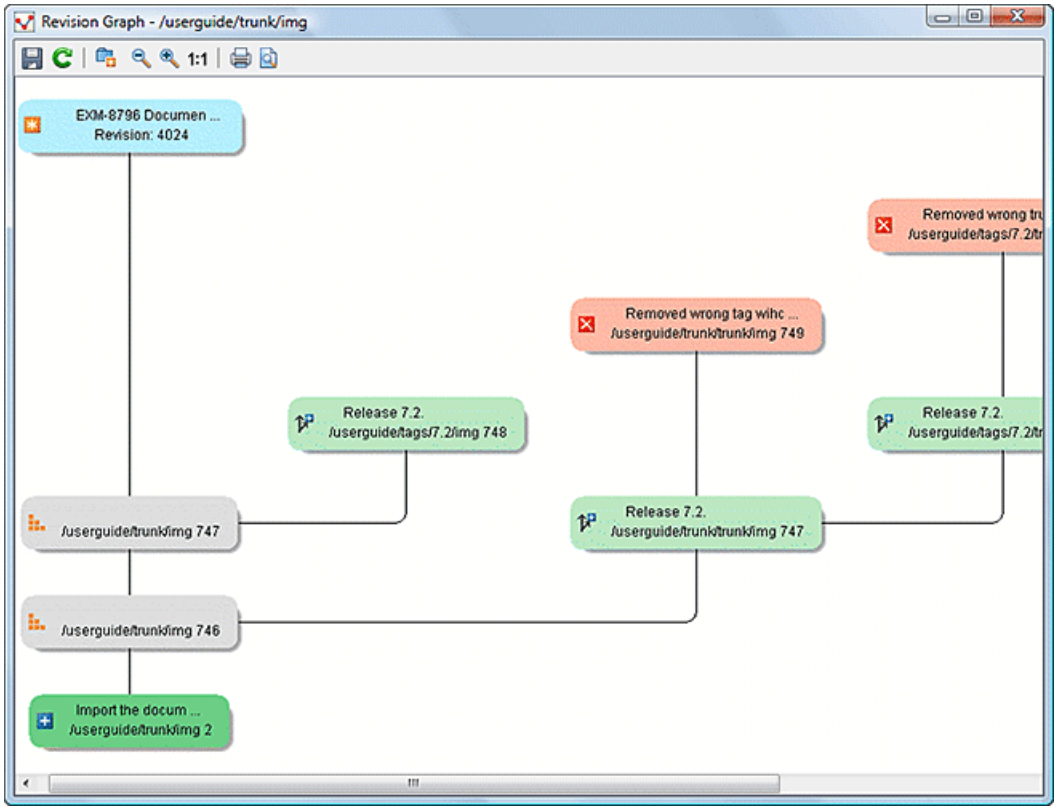

Figure 836: Revision Graph of a Directory (Direct Changes)

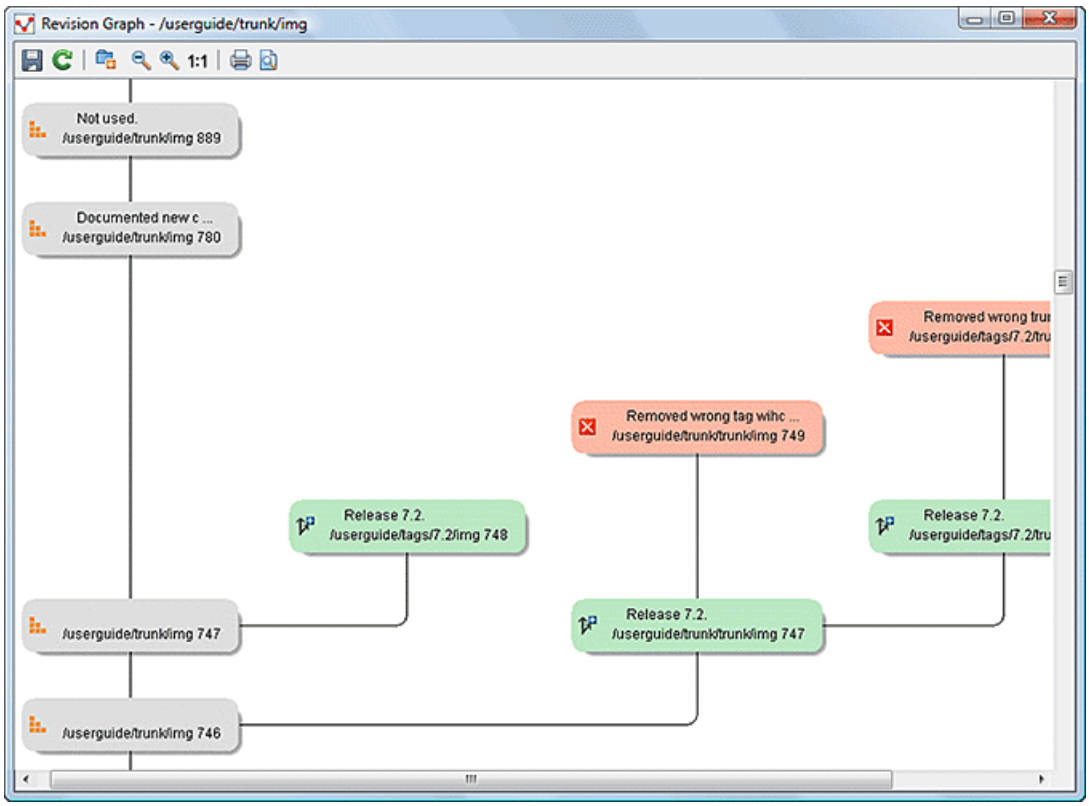

Figure 837: Revision Graph of a Directory (Including Indirect Changes)

The **Revision graph** toolbar contains the following actions:

Save as image

Saves the graphical representation as image. For a large revision graph you have to *set more memory in the startup script*. The default memory size is not enough when there are more than 100 revisions that are included in the graph.

Show/Hide indirect modifications

Switches between simplified and complete graph.

Zoom In

Zooms in the graph.

Zoom Out

Zooms out the graph. When the font reaches its minimum size, the graph nodes will display only the icons, leading to a very compact representation of the graph.

Reset scale

Resets the graphical scale to a default setting.

Print

Prints the graph.

Print preview

Offers a preview of the graph to allow you to check the information to be printed.

The contextual menu of any of the graph nodes contains the following actions:

Open

Opens the selected revision in the editor panel. Available only for files.

Open with

Opens the selected revision in the editor panel. Available only for files.

Save as

Saves the file for which the revision graph was generated, based on the selected node revision.

Copy to

Copies to the repository the item whose revision graph is displayed, using the selected revision.

Note: This action can be used to resurrect deleted items also.

Compare with HEAD

Compares the selected revision with the HEAD revision and displays the result in the diff panel. Available only for files.

Show History

Displays the history of the resource in *the History view*. Available for both files and directories.

Check out

Checks out the selected revision of the directory. Available only for directories.

Export

Opens *the **Export** dialog box* that allows you to configure options for exporting a folder from the repository to the local file system.

When two nodes are selected in the revision graph of a file the right-click menu of this selection contains only the **Compare** for comparing the two revisions corresponding to the selected nodes. If the resource for which the revision graph was built is a folder then the right-click menu displayed for a two nodes selection also contains the **Compare** action but it computes the differences between the two selected revisions as a set of directory changes. The result is displayed in the *Directory Change Set* view.

Attention: Generating the revision graph of a resource with many revisions may be a slow operation. You should enable caching for revision graph actions so that future actions on the same repository will not request the same data again from the SVN server, which will finish the operation much faster.

Oxygen XML Editor SVN Preferences

The options used in the SVN client are saved and loaded independently from the Oxygen XML Editor options. However, if Oxygen XML Editor cannot determine a set of SVN options to be loaded at startup, some of the preferences are imported from the XML Editor options (such as the License key and HTTP Proxy settings).

There is also an additional set of preferences applied to the SVN client that are set in global SVN files. There are two editing actions available in the **Global Runtime Configuration** submenu of the **Options** menu. These actions, **Edit 'config' file** and **Edit 'servers' file**, contain parameters that act as defaults applied to all the SVN client tools that are used by the same user on their login account.

Entering Local Paths and URLs

The Oxygen XML Editor includes a variety of option configuration pages or wizards that contain text boxes where you specify paths to local resources or URLs of items inside remote repositories. The Oxygen XML Editor provides support in these text boxes to make it easier to specify these paths and URLs.

Local Item Paths

The text boxes used for specifying local item paths support the following:

- *Absolute Paths* - In most cases, the Oxygen XML Editor expects absolute paths for local file system items.
- *Relative Paths* - The Oxygen XML Editor only accepts relative paths in the form ~[`/...`], where ~ is the user home directory.
- *Path Validation* - Oxygen XML Editor validates the path as you type and invalid text becomes red.
- *Drag and Drop* - You can drag files and folders from the file system or other applications and drop them into the text box.
- *Automatic Use of Clipboard Data* - If the text box is empty when its dialog box is opened, any data that is available in the system clipboard is used, provided that it is valid for that text box.

Repository Item URLs

- *Local Repository Paths* - You can use local paths (absolute or relative) to access local repositories. When you use the **Browse** button, the Oxygen XML Editor will convert the file path to a `file://` form of URL, provided that the location is a real repository.
  - *Absolute Paths* - In most cases, the Oxygen XML Editor expects absolute paths for local file system items.
  - *Relative Paths* - The Oxygen XML Editor only accepts relative paths in the form ~[`/...`], where ~ is the user home directory.
- *Peg Revisions* - For URL text boxes found inside dialog boxes where you are pulling information from the repository, you can *use peg revisions at the end of the URLs* (for example, URL`@rev1234`).

  Note: If you try to use a *peg revision* number in a dialog box where you are sending information to the repository then the peg revision number will become part of the name of the item rather than searching for the specified revision. For example, in the URL `http://host/path/inside/repo/item@100`, the item name is considered to be `item@100`.

  Tip: You can even use *peg revisions* with local repository paths. For example, `C:\path\to\local\repo@100` will be converted to `file:///C:/path/to/local/repo@100` and the **Repository browser** will display the content of the local repository as it is at revision `100`.
- *URL Validation* - Oxygen XML Editor validates the URLs as you type and invalid text becomes red. Even paths to local repositories are not accepted unless using the **Browse** button to convert them to valid URLs.
- *Drag and Drop* - You can drag URLs from other applications or text editors and drop them into the URL text box. You can also drag folders that point to local repositories, from the local file system or from other applications, and they are automatically converted to valid `file://` type URLs.
- *Automatic Use of Clipboard Data* - If the URL text box is empty when its dialog box is opened, any data that is available in the system clipboard is used, provided that it is valid for that text box. Even valid local paths will be automatically converted to `file://` type URLs.

Note: The text boxes that are in the form of a combo box also allow you to select previously used URLs, or URLs defined in the **Repositories** view.

Technical Issues

This section contains special technical issues found during the use of Syncro SVN Client.

Authentication Certificates Not Saved

If Syncro SVN Client prompts you to enter the authentication certificate, although you already provided it in a previous session, then you should make sure that your local machine user account has the necessary rights to store certificate files in the *Subversion* configuration folder (write access to *Subversion* folder and all its subfolders). Usually, it is located in the following locations:

- Windows: `[HOME_DIR]\AppData\Roaming\Subversion`
- Mac OS X and Linux: `[HOME_DIR]/.subversion`

Updating Newly Added Resources

When you want to get a resource that is part of a newly created structure of folders from the repository, you need to also get its parent folders.

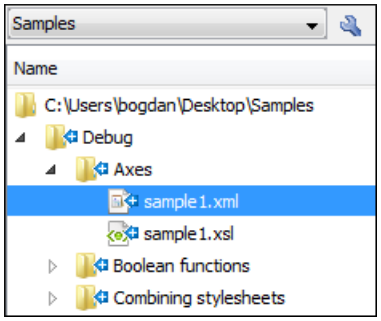

Figure 838: Incoming Changes

Syncro SVN Client allows you to choose how you want to deal with the entire structure from that moment onwards:

Update ancestor directories recursively

This option brings the entire newly added folders structure into your working copy. In this case, the update time depends on the total number of newly incoming resources, because of the full update operation (not updating only selected resource).

Update selected files only (leave ancestor directories empty)

This option brings a skeleton structure composed of the resource's parent folders only, and the selected resource at the end of the operation. All of the parent directories will have depth set to *empty* in your working copy, thus subsequent **Synchronize** operations will not report any remote modifications in those folders. If you need to update the folders to full-depth, you can use the ***Update to revision/depth*** *action* from the working copy view.

Cannot Access a Repository through HTTPS

If you have issues when trying to access a repository through HTTPS protocol, one of the possible causes can be the encryption protocol currently used by the application. This is happening when:

- You are running Oxygen XML Editor with Java 1.6 or older.
- The repository is set to use only one of the SSLv3 or TLSv1 encryption protocols.

To solve this issue, set the ***HTTPS encryption protocols*** *option* to **SSLv3 only** or **TLSv1 only** (depending on the repository configuration).

Accessing Old Items from a Repository

Usually, you point to an item from a repository using a URL. However, sometimes this might not be enough because the URL alone might point to a different item than the one you want and a *peg revision* is needed.

A Subversion repository tracks any change made to its items by using *revisions*, which contain information such as the name of the author who made the changes, the date when they were made, and a number that

uniquely identifies each of them. Over time, an item from a specific location in a repository evolves as a result of committing changes to it. When an item is deleted, its entire life cycle (all changes made to it from the moment it was created) remains recorded in the history of the repository. If a new item is created, with the same name and in the same location of the repository as a previously existing one, then both items are identified by the same URL even though they are located in different time frames. This is when a *peg revision* comes in handy. A *peg revision* is nothing more than a normal revision, but the difference between them is made by their usage. Many of the Subversion commands accept also a peg revision as a way to precisely identify an item in time, beside an *operative revision* (the revision we are interested in, regarding the used command).

Example:

To illustrate an example, consider the following:

- We created a new repository file `config`, identified by the URL `http://host.com/myRepository/dir/config`.
- The file has been created at revision `10`.
- Over time, the file was modified by committing revisions `12, 15, 17`.

To access a specific version of the file identified by the `http://host.com/myRepository/dir/config` URL, we need to use a corresponding revision (the operative revision):

- If we use a revision number less than `10`, an error is triggered, because the file has not been created yet.
- If we use a revision number between `10` and `19`, we will obtain the specific version we are interested in.

  Note: Although the file was modified in revisions `12, 15, 17`, it existed in all revisions between `10` and `19`. Starting with a revision at which the file is modified, it has the same content across all revisions generated in the repository until another revision in which it is modified again.

At this point, we delete the file, creating revision `20`. Now, we cannot access any version of the file, because it does not exist anymore in the latest repository revision. This is due to the fact that Subversion automatically uses the `HEAD` revision as a peg revision (it assumes any item currently exists in the repository if not instructed otherwise). However, using any of the revision numbers from the `10-19` interval (when the file existed) as a peg revision (beside the operative revision), will help Subversion to properly identify the time frame when the file existed, and access the file version corresponding to the operative revision. If we use a revision number greater than `19`, this will also trigger an error.

Continuing our example, suppose that at revision `30` we create a directory called `config` in the same repository location as our deleted file. This means that our new directory will be identified by the same repository address: `http://host.com/myRepository/dir/config`. If we use only this URL in any Subversion command, we will access the new directory. We will also access the same directory if we use any revision number equal with or greater than `30` as peg revision. However, if we are interested in accessing an old version of the previously existing file, then we must use one of the revisions that existed (`10-19`), as a peg revision, similar to the previous case.

Checksum Mismatch Error

A *Checksum Mismatch* error could happen if an operation that sends or retrieves information from the repository to the working copy is interrupted. This means that there is a problem with the synchronization between a local item and its corresponding remote item.

If you encounter this error, try the following:

1. Identify the parent directory of the file that caused the error (the file name should be displayed in the error message).

   Note: If the parent directory is the root of the working copy or if it contains a large amount of items it is recommended that you check out the working copy again, rather than continuing with the rest of this procedure.
2. Identify the *current depth* of that directory.
3. Update the parent directory using the **Update to revision/depth** action that is available from the contextual menu or the **Working copy** menu.

   a. For the **Depth** option, select **This folder only (empty)**.

Warning: If you have files with changes in this directory, those changes could be lost. You should commit your changes or move the files to another directory outside the working copy prior to proceeding with this operation.

4. After clicking **OK** the contents of the directory will be erased and the directory is be marked as having *an empty depth*.
5. Once again, update the same directory using the **Update to revision/depth** action.
   a. This time, for the **Depth** option, select the depth that was previously identified in step 2.
6. If you moved modified files to another directory outside the working copy, move them back to the original location inside the working copy.

If this procedure does not solve the error, you need to check out the working copy again and move possible changes from the old working copy to the new one.

External Tools

A command-line tool can be started in the Oxygen XML Editor user interface as if from the command line of the operating system shell. Oxygen XML Editor offers you the option of integrating such a tool by specifying just the command line for starting the executable file and its working directory. To integrate such a tool, *open the **Preferences** dialog box **(Options > Preferences)*** and go to ***External Tools*** (or select **Configure** from the **Tools** > **External Tools** menu).

The ***External Tools** preferences page* presents a list of the external tools that have been configured. Once *a tool has been configured*, you can open it by selecting it from the **Tools** > **External Tools** menu or from the  **External Tools** drop-down menu on the toolbar (the **Tools** toolbar needs to be selected in the ***Configure Toolbars** dialog box*). You can also *assign a keyboard shortcut* to be used to launch the tool.

If the external tool is applied on one of the files opened in Oxygen XML Editor, the ***Save all files before calling external tools** option* (in the **Open/Save** preference page) should be selected so that all edited files are automatically saved when an external tool is applied.

When an external tool is launched, the icon on the toolbar changes to a stop icon () and you can use this button to stop the tool. When the tool has finished running (or you close it), the icon changes back to the original icon ().

Note: Even though you can stop the external tool by invoking the stop action while it is running, that does not necessarily mean it will also stop the processes spawned by that external tool. For instance, if you stop an external tool that runs a batch file, the batch may be stopped but without actually stopping the processes that the batch was running at that time.

Example: Integrating the Ant Tool

This is an example procedure for integrating *the Ant build tool* into Oxygen XML Editor:

1. *Download* and *install Apache Ant* on your computer.
2. Test your *Ant* installation from the command-line interface in the directory where you want to use *Ant* from. For example, run the `clean` target of your `build.xml` file `C:\projects\XMLproject\build.xml`:

   ```
   ant clean
   ```

3. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **External Tools** (or select **Configure** from the **Tools** > **External Tools** menu).
4. Click the **New** button to create a new external tool entry and enter the following information:
   - **Name** - For example, `Ant tool`.
   - **Working directory** - For example, `C:\projects\XMLproject`.
   - **Command line** - For example, `"C:\projects\XMLproject\ant.bat" clean`.
5. Click **OK** to add the new tool to the list of external tools.
6. Run the tool from **Tools** > **External Tools** > **Ant tool**. You can see the output in the system console:

```
    Started: "C:\projects\XMLproject\ant.bat" clean
    Buildfile: build.xml

    clean:
    [echo] Delete output files.
    [delete] Deleting 5 files from C:\projects\XMLproject

    BUILD SUCCESSFUL
    Total time: 1 second
```

Common Problems

19

Topics:

- *Performance Problems and Solutions*
- *Misc Problems and Solutions*

This section provides a collection of common performance and other types of problems that might be encountered when using Oxygen XML Editor, along with their possible solutions.

Performance Problems and Solutions

This section contains solutions for some common performance problems that may appear when running Oxygen XML Editor.

Related Information:

Editing Documents with Long Lines on page 940
Loading Large Documents on page 939
External Tools on page 1763

Display Problems on Linux or Solaris

Problem

I experience display problems (such as screen freezes) on Linux or Solaris.

Solution

Add the following startup parameter: -Dsun.java2d.pmoffscreen=false.

Out of Memory on External Processes

Problem

Oxygen XML Editor throws an *Out Of Memory* error when trying to generate PDF output with the built-in Apache FOP processor.

Solution

*Open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **XML** > **XSLT-FO-XQuery** > **FO Processors**, and increase the value of the ***Memory available to the built-in FOP** option*.

For external XSL-FO processors, XSLT processors, and external tools, the maximum value of the allocated memory is set in the command line of the tool using the -Xmx parameter set to the Java virtual machine.

Related Information:

FO Processors Preferences on page 130

Too many nested apply-templates calls Error When Running a Transformation

Problem

I'm getting the error message **Too many nested apply-templates calls** when I try to transform my DocBook file to HTML using default Oxygen XML Editor DocBook to HTML transformation scenario.

Solution

Most likely, this is the result of a masked stack overflow error that can be solved by increasing the stack size (**-Xss**) to 4MB. Try setting a new VM option with the value **-Xss4m**. You can try to slowly increase this to larger values (e.g. **-Xss5m** or **-Xss6m**). Note that this consumes memory on a per thread basis (Oxygen XML Editor can have tens of threads), so using a very large value here can backfire and leave Oxygen XML Editor without memory.

Related Information:

Setting a Java Virtual Machine Parameter when Launching Oxygen XML Editor on page 182

Performance Issues with Large Documents

Problem

The performance of the application slows down considerably over time when working with large documents.

Solution

A possible cause is that the application needs more memory to run properly. You can increase the maximum amount of memory available to Oxygen XML Editor by *setting the -Xmx parameter in a configuration file* that is specific to the platform that runs the application.

Attention: The maximum amount of memory should not be equal to the physical amount of memory available on the machine because in that case the operating system and other applications will have no memory available.

When installed on a multiple user environment, each instance of Oxygen XML Editor will be allocated the amount stipulated in the memory value. To avoid degrading the general performance of the host system, ensure that the amount of memory available is optimally apportioned for each of the expected instances.

Note: When starting Oxygen XML Editor from the icon created on the Start menu or Desktop in Windows (or from the shortcut created on the Linux desktop), the default maximum memory available to the application is set to 40% of the amount of physical RAM, but not more than 700 MB.

When starting Oxygen XML Editor from a command-line script, the default maximum memory is 512 MB.

Misc Problems and Solutions

This chapter presents common problems that may appear when running the application along with solutions for these problems.

'Address Family Not Supported by Protocol Family; Connect' Error

Problem

I have experienced the following error: *"Address Family Not Supported by Protocol Family; Connect"*. How do I solve it?

Solution

This seems to be an IPv6 connectivity problem. By default, the Java runtime used by Oxygen XML Editor prefers to create connections via IPv6, if the support is available. However, even though it is available in appearance, IPv6 sometimes happens to be configured incorrectly on some systems.

A quick solution for this problem is to set the `java.net.preferIPv4Stack` Java property to `true` (`java.net.preferIPv4Stack=true`), by following this procedure:

1. Create a file named `custom_commons.vmoptions` and add on a single line – `Djava.net.preferIPv4Stack=true`. Then save the file and copy it to the Oxygen XML Editor installation folder (may need admin access).
2. Restart Oxygen XML Editor.
3. Make sure the procedure was successful by going to **Help** > **About** > **System properties** and check that the value of the `java.net.preferIPv4Stack` property is `true`.

Alignment Issues of the Main Menu on Linux Systems Based on Gnome 3.x

Problem

On some Linux systems based on Gnome 3.x (Ubuntu 11.x, 12.x), the main menu of Oxygen XML Editor has alignment issues when you navigate it using your mouse.

Solutions

This is a known problem caused by Java SE 6 1.6.0_32 and earlier. You can resolve this problem using the latest Java SE 6 JRE from Oracle. To download the latest version, go to *http://www.oracle.com/technetwork/java/javase/downloads/index.html*.

To bypass the JRE bundled with Oxygen XML Editor, go to the installation directory of Oxygen XML Editor and rename or move the `jre` folder. If Oxygen XML Editor does not seem to locate the system JRE, either set the JAVA_HOME environment variable to point to the location where you have installed the JRE, or you can simply copy that folder with the JRE to the installation directory and rename it to `jre` to take the place of the bundled JRE.

Archive Distribution Fails to Run on Mac OS 10.12 (Sierra)

Problem

For versions prior to 18.1, the classic archive distributions of Oxygen XML Editor (`.zip` or `.tar.gz`) fail to run on Mac OS 10.12 (Sierra).

Solution

This happens because the archives get quarantined and Mac OS 10.12 (Sierra) treats quarantined apps differently than older versions and isolates them from their parent folder at launch. If Oxygen XML Editor was already installed when you upgraded to Mac OS 10.12 (Sierra), there are no problems.

If Oxygen XML Editor was not already installed, or you need to reinstall an older version (prior to version 18.1), the quarantine flag must be removed for the entire content of the Oxygen XML Editor installation directory or the individual applications. To resolve this issue, follow these steps:

1. Open a *Terminal* window and change the directory to the folder where Oxygen XML Editor is located.
2. Run the following command:

   ```
   xattr -dr com.apple.quarantine oxygen/
   ```

   where "oxygen" is the actual name of the Oxygen XML Editor directory.

   If Oxygen XML Editor is in a location that requires administrator privileges for write access, you need to run the command from an administrator account and prefix the command with `sudo`. You will then be prompted to enter your password.

Cannot Associate Oxygen XML Editor With a File Type on My Windows Computer

Problem

I cannot associate the Oxygen XML Editor application with a file type on my Windows computer by right clicking a file in Windows Explorer, selecting **Open With** > **Choose Program** and browsing to the file oxygen19.0.exe. When I select the file oxygen19.0.exe in the Windows file browser dialog box, the Oxygen XML Editor application is not added to the list of applications in the **Open With** dialog box. What can I do?

Solution

The problem is due to some garbage Windows registry entries remained from versions of Oxygen XML Editor older than version 9.0. Uninstall all your installed versions of Oxygen XML Editor and run a registry cleaner application for cleaning these older entries. After that just reinstall your current version of Oxygen XML Editor and try again to create the file association.

Cannot Connect to SVN Repository from Repositories View

Problem

I cannot connect to a SVN repository from the **Repositories** view of SVN Client. How can I find more details about the error?

Solution

First check that you entered the correct URL of the repository in the **Repositories** view. Also check that a SVN server is running on the server machine specified in the repository URL and is accepting connections from SVN clients. You can check that the SVN server accepts connections with the command line SVN client from CollabNet.

If you try to access the repository with a `svn+ssh` URL also check that a SSH server is running on port 22 on the server machine specified in the URL.

If the above conditions are verified and you cannot connect to the SVN repository please generate a logging file on your computer and send the logging file to support@oxygenxml.com. For generating a logging file you need to create a text file called `log4j.properties` in the install folder with the following content:

```
log4j.rootCategory= debug, R2

log4j.appender.R2=org.apache.log4j.RollingFileAppender
log4j.appender.R2.File=logging.log
log4j.appender.R2.MaxFileSize=12000KB
log4j.appender.R2.MaxBackupIndex=20
log4j.appender.R2.layout=org.apache.log4j.PatternLayout
log4j.appender.R2.layout.ConversionPattern=%r %p [ %t ] %c - %m%n
```

Restart the application, reproduce the error, close the application and send the file `logging.log` generated in the install directory to support@oxygenxml.com.

Cannot Open XML Files in Internet Explorer

Problem

Before installing Oxygen XML Editor I had no problems opening XML files in Internet Explorer. Now when I try to open an XML file in Internet Explorer it opens the file in Oxygen XML Editor. How can I load XML files in Internet Explorer again?

Solution

XML files are opened in Oxygen XML Editor because Internet Explorer uses the Windows system file associations for opening files and you associated XML files with Oxygen XML Editor in the installer panel called **File Associations**. Therefore, Internet Explorer opens XML files with the associated Windows application.

By default, the association with XML files is disabled in the Oxygen XML Editor installer panel called **File Associations**. When you enabled it, the installer displayed a warning message about the effect that you experience right now.

For opening XML files in Internet Explorer, you have to set Internet Explorer as the default system application for XML files. For example, you can do so by following this procedure:

1. Right-click the XML file in Windows Explorer and select **Open With** > **Choose Default Program**.
2. Expand the section with the down-arrow and select IE in the list of applications.
3. Select the **Always use the selected program** option.

If XML files are still not opened in Internet Explorer, create a file named `revert.vbs` with the following content:

```
function revert()
  Set objShell = CreateObject("WScript.Shell")
  objShell.RegWrite "HKCR\.xml\", "xmlfile", "REG_SZ"
  objShell.RegWrite "HKCR\.xml\Content Type", "text/xml", "REG_SZ"
end function

revert()
```

Then run the following command from a command line:

```
wscript revert.vbs
```

Compatibility Issue Between Java and Certain Graphics Card Drivers

Problem

Under certain settings, a compatibility issue can appear between Java and some graphics card drivers, which results in the text from the editor (in **Author** or **Text** mode) being displayed garbled.

Solution

If you encounter this problem, update your graphics card driver. Another possible workaround is, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Appearance** > **Fonts**, and set the value of the ***Text antialiasing** option* to ON.

Note: If this workaround does not resolve the problem, set the ***Text antialiasing** option* to other values.

Crash at Startup on Windows with an Error About the `nvoglv32.dll` File

Problem

I try to start Oxygen XML Editor on Windows but it crashed with an error message about “Fault Module Name: nvoglv32.dll”. What is the problem?

Solution

It is an OpenGL driver issue that can be avoided by creating an empty file called `opengl32.dll` in the Oxygen XML Editor install folder (if you start Oxygen XML Editor with the shortcut created by the installer on the Start menu or on Desktop) or in the subfolder `bin` of the home folder of the Java virtual machine that runs Oxygen XML Editor (if you start Oxygen XML Editor with the `oxygen.bat` script). The home folder of the Java virtual machine that runs Oxygen XML Editor is the value of the `java.home` property that is available in the **System properties** tab of the **About** dialog box (opened from the **Help** > **About** menu.

Damaged File Associations on OS X

Problem

After upgrading OS X and Oxygen XML Editor, it is no longer associated to the appropriate file types (such as XML, XSL, XSD, etc.) How can I create the file associations again?

Solution

The upgrade damaged the file associations in the LaunchService Database on your OS X machine. You can rebuild the LaunchService Database with the following procedure. This will reset all file associations and will rescan the entire file system searching for applications that declare file associations and collecting them in a database used by Finder.

1. Find all the Oxygen XML Editor installations on your hard drive.
2. Delete them by dragging them to the Trash.
3. Clear the Trash.
4. Unpack the Oxygen XML Editor installation kit on your desktop.
5. Copy the contents of the archive into the folder `/ Applications / Oxygen`.
6. Run the following command in a Terminal:

```
/System/Library/Frameworks/CoreServices.framework/Versions/A/Frameworks/
LaunchServices.framework/Versions/A/Support/lsregister -kill -r -domain local -
domain system -domain user
```

7. Restart Finder with the following command:

```
killall Finder
```

8. Create an XML or XSD file on your desktop. It should have the Oxygen XML Editor icon.
9. Double-click the file.
10. Accept the confirmation.

Result: When you start Oxygen XML Editor, the file associations should work correctly.

Details to Submit in a Request for Technical Support Using the Online Form

Problem

What details should I add to my request for technical support on the online form in the product website?

Solution

When completing a request for Technical Support using the online form, include as many details as possible about your problem. For problems where a simple explanation may not be enough for the Technical Support team to reproduce or address the issue (such as server connection errors, unexpected delays while editing a document, an application crash, etc.), you should generate a log file and attach it to the problem report. In the case of a crash, you should also attach the crash report file generated by your operating system.

If the text content of an XML document you want to send to the support team contains sensitive or private information, you can use the ***Randomize XML text content*** *action* to create filler content. Before using this action, you need to copy the initial XML resources and save them in a separate folder. Otherwise, you might lose your original information.

To generate an Oxygen XML Editor log file, follow these steps:

1. Create a text file called `log4j.properties` in the application installation folder, with the following content:

```
log4j.rootCategory= debug, R2

log4j.appender.R2=org.apache.log4j.RollingFileAppender
log4j.appender.R2.File=${user.home}/Desktop/oxygenLog/oxygen.log
log4j.appender.R2.MaxFileSize=12000KB
log4j.appender.R2.MaxBackupIndex=20
log4j.appender.R2.layout=org.apache.log4j.PatternLayout
log4j.appender.R2.layout.ConversionPattern=%r %p [ %t ] %c - %m%n
```

2. Restart the application.
3. Reproduce the error.
4. Close the application.
5. Delete the `log4j.properties` file because it might cause performance issues if you leave it in the installation folder.

Important: The logging mode may severely decrease the performance of the application. Therefore, please do not forget to delete the `log4j.properties` file when you are done with the procedure.

The resulting log file is named `oxygen#.log` (for example, `oxygen.log`, `oxygen.log.1`, `oxygen.log.2`, etc.) and is located in the `Desktop\oxygenLog` folder.

DITA Map Transformation Fails (Cannot Connect to External Location)

Problem

DITA map transformation fails because it cannot connect to an external location.

Solution

The transformation is run as an external Ant process so you can continue using the application as the transformation unfolds. All output from the process appears in the **DITA Transformation** tab.

The HTTP proxy settings are used for the Ant transformation, so if the transformation fails because it cannot connect to an external location, you can check the *the **Proxy** preferences page*

DITA Map WebHelp Transformation Fails (Duplicate Topic References Found)

Problem

DITA Map WebHelp transformation fails with a message that indicates duplicate topic references were found.

Solution

By default the WebHelp transformation uses the `force-unique` parameter set to **true** to force the transformation to create unique output files for each instance of a resource when a map contains multiple references to a single topic. However, there are cases when this feature does not work as expected and the duplicate topic references are not handled properly.

To solve this issue, you should manually set a unique `copy-to` attribute on any duplicate topic reference that was not handled automatically by DITA-OT:

```
<map>
...
  <topicref href="../topics/MyTopic.dita"/>
...
  <topicref href="../topics/MyTopic.dita" copy-to="../topics/MyTopic-2.dita"/>
</map>
```

DITA PDF Transformation Fails

Problem

The DITA to PDF transformation fails.

Solution

To generate the PDF output, Oxygen XML Editor uses the DITA Open Toolkit.

If your transformation fails you can detect some of the problems that caused the errors by running *the **Validate and Check for Completeness** action*. Depending on the options you select when you run it, this action reports errors such as topics referenced in other topics but not in the *DITA map*, broken links, and missing external resources.

You can analyze the **Results** tab of the DITA transformation and search for messages that contain text similar to `[fop] [ERROR]`. If you encounter this type of error message, edit the transformation scenario you are using and set the **clean.temp** parameter to **no** and the **retain.topic.fo** parameter to **yes**. Run the transformation, go to the temporary directory of the transformation, open the `topic.fo` file and go to the line indicated by the error. Depending on the XSL FO context try to find the DITA topic that contains the text that generates the error.

If none of the above methods helps you, go to **Help** > **About** > **Components** > **Frameworks** and check what version of the DITA Open Toolkit you are using. Copy the whole output from the DITA OT console output and either report the problem on the DITA User List or to support@oxygenxml.com.

DITA to CHM Transformation Fails

Oxygen XML Editor uses the DITA Open Toolkit and the HTML Help compiler (part of the Microsoft HTML Help Workshop) to transform DITA content into *Compiled HTML Help* (or *CHM* in short).

It is a good practice to validate the *DITA map* before executing the transformation scenario. To do so, run *the **Validate and Check for Completeness** action*. Depending on the selected options, this action reports errors, such as topics referenced in other topics (but not in the *DITA map*), broken links, and missing external resources.

However, the execution of the transformation scenario may still fail. Reported errors include the following:

Problem: Cannot Open File

```
[exec] HHC5010: Error: Cannot open "fileName.chm". Compilation stopped.
```

Solution: Cannot Open File

This error occurs when the CHM output file is opened and the transformation scenario cannot rewrite its content. To solve this issue, close the CHM help file and run the transformation scenario again.

Problem: Compilation Failed

```
[exec] HHC5003: Error: Compilation failed while compiling fileName
```

Solution: Compilation Failed

Possible causes of this error are:

- The processed file does not exist. Fix the file reference before executing the transformation scenario again.
- The processed file has a name that contains space characters. To solve the issue, remove any spacing from the file name and run the transformation scenario again.

Compiled HTML Help (CHM) Output Format on page 1042

Drag and Drop Without Initial Selection Does Not Work

Problem

When I try to drag with the mouse an unselected file from the ***Project** view* or the ***DITA Maps Manager** view*, the drag never starts, it only selects the resource. I need to drag the resource again after it becomes selected. As a result any drag and drop without initial selection becomes a two step operation. How can I fix this?

Solution

This is *a bug* present in JVM versions prior to 1.5.0_09. This issue is fixed in 1.5.0_09 and newer versions. See the *installation instructions* for setting a specific JVM version for running the Oxygen XML Editor application.

Gray Window on Linux With the Compiz / Beryl Window Manager

Problem

I try to run Oxygen XML Editor on Linux with the Compiz / Beryl window manager but I get only a gray window that does not respond to user actions. Sometimes the Oxygen XML Editor window responds to user actions but after opening and closing an Oxygen XML Editor dialog or after resizing the Oxygen XML Editor window or a view of the Oxygen XML Editor window the content of this window becomes gray and it does not respond to user actions. What is wrong?

Solution

Sun Microsystems' Java virtual machine *does not support the Compiz window manager and the Beryl one very well*. It is expected that better support for Compiz / Beryl will be added in future versions of their Java virtual machine. You should turn off the special effects of the Compiz / Beryl window manager before starting the Oxygen XML Editor application or switch to other window manager.

Handshake Failure Error When Accessing an HTTPS (SSL) Resource

Problem

When attempting to access an HTTPS (SSL) resource, I receive a **handshake_failure** error. What can I do?

Solution

The issue is most likely due to the limitation of Java cryptography capabilities. A solution might be to download and deploy *Java Cryptography Extension (JCE) Unlimited Strength Jurisdiction Policy Files 8 (for Java 8)*.

Warning: It is possible that this may not be legal in your country. Please understand that you bare legal responsibility for activating unlimited strength Java cryptography capabilities, so you must have the legal right to use such cryptography (please consult your export/import control counsel or attorney to determine the exact requirements for your jurisdiction).

To deploy it in Oxygen XML Editor, unpack the downloaded zip archive and move the two jar files (**local_policy.jar** and **US_export_policy.jar**) from **UnlimitedJCEPolicyJDK8** to the following directory, overwriting existing files:

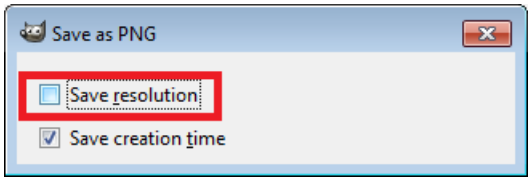
- **Windows** - *[OXYGEN_INSTALL_DIR]*`/jre/lib/security`
- **Linux** - *[OXYGEN_INSTALL_DIR]*`/jre/lib/security`
- **Mac OS X** - *[OXYGEN_INSTALL_DIR]*`/jre.bundle/Contents/Home/jre/lib/security`

Image Appears Stretched Out in the PDF Output

Problem

When publishing XML content (DITA, DocBook, etc.), images are sometimes scaled up in the PDF outputs but are displayed perfectly in the HTML (or WebHelp) output.

Solution



PDF output from XML content is obtained by first obtaining a intermediary XML format called XSL-FO and then applying an XSL-FO processor to it to obtain the PDF. This stretching problem is caused by the fact that all XSL-FO processors take into account the DPI (dots-per-inch) resolution when computing the size of the rendered image.

The PDF processor that comes out of the box with the application is the open-source Apache FOP processor. Here is what Apache FOP does when deciding the image size:

1. If the XSL-FO output contains width, height or a scale specified for the image `external-graphic` tag, then these dimensions are used. This means that if in the XML (DITA, DocBook, etc.) you set explicit dimensions to the image they will be used as such in the PDF output.
2. If there are no sizes (width, height or scale) specified on the image XML element, the processor looks at the image resolution information available in the image content. If the image has such a resolution saved in it, the resolution will be used and combined with the image width and height to obtain the rendered image dimensions.
3. If the image does not contain resolution information inside, Apache FOP will look at the FOP configuration file for a default resolution. The FOP configuration file for XSLT transformations that output PDF is located in the *[OXYGEN_INSTALL_DIR]*`/lib/fop.xconf`. DITA publishing uses the DITA Open Toolkit that has the Apache FOP configuration file located in [*DITA-OT-DIR*`/plugins/org.dita.pdf2/fop/conf/fop.xconf`. The configuration file contains two XML elements called `source-resolution` and `target-resolution`. The values set to those elements can be increased (usually a DPI value of 110 or 120 should render the image in PDF the same as in the HTML output).

The commercial **RenderX XEP** XSL-FO processor behaves similarly but as a fallback it uses 120 as the DPI value instead of using a configuration file.

Tip: It is best to save your images without any DPI resolution information. For example, when saving a PNG image in the open-source GIMP image editor, you do not want to save the resolution.

This allows you to control the image resolution from the configuration file for all referenced images.

Increasing the Memory for the Ant Process

Problem

The Ant build process ran out of memory.

Solution

For details about setting custom JVM arguments to the Ant build process, see *JVM Arguments*.

JPEG CMYK Color Space Issues

Problem

JPEG images with CMYK color profile having the color profiles embedded in the image should be properly rendered in the **Author** mode.

Solution

If the color profile information is missing from the JPEG image but you have the ICC file available, you can copy the `profileFileName.icc` to the *`[OXYGEN_INSTALL_DIR]`*`\lib` directory.

If the color space profile is missing, JPEG images that have the CMYK color space are rendered without taking the color profile into account. The **Unsupported Image Type** message is displayed above the image.

Keyboard Shortcuts Do Not Work

Problem

The keyboard shortcuts listed in the *Menu Shortcut Keys preferences* do not work. What can I do?

Solution

Usually this happens when a special keyboard layout is set in the operating system that generates other characters than the usual ones for the keys of a standard keyboard. For example if you set the extended Greek layout for your keyboard you should return to the default Greek layout or to the English one. Otherwise, the Java virtual machine that runs the application will receive other key codes than the usual ones for a standard keyboard.

Keyboard Language Resets to Default on Windows

Problem

In Windows, I have set a specific language for my keyboard other than the default language and while using Oxygen XML Editor, it keeps getting reset to the default language.

Solution

The default Windows shortcut keys for switching the input language is **Left Alt+Shift** and trying to use various shortcuts in Oxygen XML Editor that involves combinations of those two keys is probably resetting your input language to the default setting if you accidentally press those two keys without a third combination. You can change the Windows shortcut keys that are assigned to the input language by going to the control panel and searching for the **Switch input languages** option. For example, in Windows 10, go to **Control Panel** > **Language** > **Advanced Setting**. In the **Switching input methods** section, click on **Change language bar hot keys**. Click the **Change Key Sequence** button. This opens a dialog box that allows you to switch the shortcut keys for the input language or keyboard layout.

MSXML 4.0 Transformation Issues

Problem

If the latest MSXML 4.0 service pack is not installed on your computer, you are likely to encounter the following error message in the ***Results** panel* when you run a transformation scenario that uses the MSXML 4.0 transformer.

Example Error Message:

```
Could not create the 'MSXML2.DOMDocument.4.0' object.
Make sure that MSXML version 4.0 is correctly installed on the machine.
```

Solution

To fix this issue, go to the Microsoft website and get the latest MSXML 4.0 service pack.

Navigation to the web page was canceled when viewing CHM on a Network Drive

Problem

When viewing a CHM on a network drive, if you only see the TOC and an empty page displaying “Navigation to the web page was canceled” note that this is normal behavior. The Microsoft viewer for CHM does not display the topics for a CHM opened on a network drive.

Solution

As a workaround, copy the CHM file on your local system and view it there.

Out Of Memory Error When Opening Large Documents

Problem

I am trying to open a file larger than 100 MB to edit it in Oxygen XML Editor, but it keeps telling me it runs out of memory (**OutOfMemoryError**). What can I do?

Solution

You should make sure that the minimum limit of document size that enables the support for editing large documents (the value of the ***Optimize loading in the Text edit mode for files over** option*) is less than the size of your document. That will enable the optimized support for large documents. If that fails and you still get an Out Of Memory error you should *increase the memory available to Oxygen XML Editor*.

Other tips:

- Make sure that you close other files before opening the large file.
- You can set the default editing mode *in the Preferences dialog box*. The **Text** editing mode uses less memory than other editing modes.
- If the file is too large for the editor to handle, you can *open it in for viewing in **Large File Viewer***.

Oxygen XML Editor Crashed on My Mac OS X Computer

Problem

Oxygen XML Editor crashed the Apple Java virtual machine/Oxygen XML Editor could not start up on my OS X computer due to a JVM crash. What can I do?

Solution

Usually it is an incompatibility between the Apple JVM and a native library of the host system. More details are available in the crash log file generated by OS X and reported in the crash error message.

Oxygen XML Editor Takes Several Minutes to Start

Problem

Some anti-virus software can cause Java applications, such as Oxygen XML Editor, to start very slowly due to scanning of compressed archives (such as the *JAR* libraries that all Java applications use).

Solution

A possible solution is to add the Oxygen XML Editor folder to the list of exceptions in the anti-virus software settings.

PDF Processing Fails When Publishing DITA Content

There are cases when publishing DITA content fails when creating a PDF file. This topic lists some common problems and solutions.

Problem: Cannot Save PDF

The FO processor cannot save the PDF at the specified target. The console output contains messages like this:

```
[fop] [ERROR] Anttask - Error rendering fo file:
C:\samples\dita\temp\pdf\oxygen_dita_temp\topic.fo
<Failed to open C:\samples\dita\out\pdf\test.pdf>
Failed to open samples\dita\out\pdf\test.pdf
.............
[fop] Caused by: java.io.FileNotFoundException:
C:\Users\radu_coravu\Desktop\bev\out\pdf\test.pdf
(The process cannot access the file because it is being used by another process)
```

Solution: Cannot Save PDF

Such an error message usually means that the PDF file is already opened in a PDF reader application. The solution is to close the open PDF before running the transformation.

Problem: Table Contains More Cells Than Defined in Colspec

One of the DITA tables contains more cells in a table row than the defined number of `colspec` elements. The console output contains messages like this:

```
[fop] [ERROR] Anttask - Error rendering fo file:
D:\projects\eXml\samples\dita\flowers\temp\pdf\oxygen_dita_temp\topic.fo
<net.sf.saxon.trans.XPathException: org.apache.fop.fo.ValidationException:
The column-number or number of cells in the row overflows the number of
fo:table-columns specified for the table.
(See position 179:-1)>net.sf.saxon.trans.XPathException:
org.apache.fop.fo.ValidationException: The column-number or number of cells
in the row overflows the number of fo:table-columns specified for the table.
(See position 179:-1)
[fop]  at org.apache.fop.tools.anttasks.FOPTaskStarter.renderInputHandler
(Fop.java:657)
[fop]  at net.sf.saxon.event.ContentHandlerProxy.startContent
(ContentHandlerProxy.java:375)
.............
[fop] D:\projects\samples\dita\flowers\temp\pdf\oxygen_dita_temp\topic.fo ->
D:\projects\samples\dita\flowers\out\pdf\flowers.pdf
```

Solution: Table Contains More Cells Than Defined in Colspec

To resolve this issue, correct the `colspec` attribute on the table that caused the issue. To locate the table that caused the issue:

1. Edit the transformation scenario and set the parameter `clean.temp` to no.
2. Run the transformation, open the `topic.fo` file in Oxygen XML Editor, and look in it at the line specified in the error message (`See position 179:-1`).
3. Look around that line in the XSL-FO file to find relevant text content that you can use (for example, with the **Find/Replace in Files** action in the ***DITA Maps Manager*** *view*) to find the original DITA topic for which the table was generated.

Problem: Broken Link

There is a broken link in the generated XSL-FO file. The PDF is generated but contains a link that is not working. The console output contains messages like this:

```
[fop] 1248 WARN [ main ] org.apache.fop.apps.FOUserAgent -
Page 6: Unresolved ID reference "unique_4_Connect_42_wrongID" found.
```

Solution: Broken Link

To resolve this issue:

1. Use the  **Validate and Check for Completeness** action available in the ***DITA Maps Manager*** *view* to find such problems.
2. If you publish to PDF using a *DITAVAL* filter, select the same DITAVAL file in the **DITA Map Completeness Check** dialog box.
3. If the  **Validate and Check for Completeness** action does not discover any issues, edit the transformation scenario and set the `clean.temp` parameter to no.
4. Run the transformation, open the `topic.fo` file in Oxygen XML Editor, and search for the *unresolved ID references* (for example: `unique_4_Connect_42_wrongID`).
5. Look in the XSL-FO file to find relevant text content that you can use (for example, with the **Find/Replace in Files** action in the ***DITA Maps Manager*** *view*) to find the original DITA topic for which the table was generated.

Performance is Slow Using Oxygen XML Editor With Remote Desktop

Problem

When trying to run Oxygen XML Editor in a Remote Desktop Protocol (RDP) environment, the performance is slow and choppy.

Solution

Running a standalone version of Oxygen XML Editor over a slow RDP connection may result in performance issues. As a workaround, we suggest that you try to run Oxygen XML Editor as an Eclipse plugin when working with a slow RDP connection.

Saxon 9.7 Transformer Issues

Problem

I have upgraded to Oxygen XML Editor version 19.0 (which comes bundled with Saxon 9.7) and I am experiencing issues when trying to use the Saxon 9.7 transformer. Is it possible to use the Saxon 9.6 transformer with Oxygen XML Editor version 19.0 or later?

Solution

There is a plugin available that can be installed and it allows you to use Saxon 9.6. To install it, follow these instructions:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Select the *default* update site from the drop-down menu (**http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml**).
3. Select the **Saxon 9.6 XSLT and XQuery Transformer** plugin and click **Next**.
4. Select the **I accept all terms of the end user license agreement** option and click **Finish**.
5. Restart the application.

Result: When you configure the transformation scenario, you will now have the option to choose the Saxon 9.6 transformer.

Scroll Function of my Notebook Trackpad is Not Working

Problem

I got a new notebook (Lenovo Thinkpad™ with Windows) and noticed that the scroll function of my trackpad is not working in Oxygen XML Editor.

Solution

It is a problem with the Synaptics™ trackpads that can be fixed by adding the following lines to the `C:\Program Files\Synaptics\SynTP\TP4table.dat` file:

```
*,*,oxygen19.1.exe,*,*,*,WheelStd,1,9
*,*,oxygenAuthor19.1.exe,*,*,*,WheelStd,1,9
*,*,oxygenDeveloper19.1.exe,*,*,*,WheelStd,1,9
*,*,syncroSVNClient.exe,*,*,*,WheelStd,1,9
*,*,diffDirs.exe,*,*,*,WheelStd,1,9
*,*,diffFiles.exe,*,*,*,WheelStd,1,9
```

Segmentation Fault Error on Mac OS X

Problem

On my Mac OS X machine the application gives a *Segmentation fault* error when I double-click the application icon. Sometimes it gives no error but it does not start. What is the problem?

Solution

Make sure you have the latest Java update from the Apple website installed on your Mac OS X computer. If installing the latest Java update does not solve the problem, copy the file `JavaApplicationStub` from the `/System/Frameworks/JavaVM.framework` folder to the `Oxygen.app/Contents/MacOS` folder. For browsing the `.app` folder you have to **(CMD+click)** the Oxygen XML Editor icon and select **Show Package Contents**.

Set Specific JVM Version on Mac OS X

Problem

How do I configure Oxygen XML Editor to run with the version X of the Apple Java virtual machine on my Mac OS X computer?

Solution

Oxygen XML Editor uses the first JVM from the list of preferred JVM versions set on your Mac computer that has a version number 1.6.0 or higher. You can move your desired JVM version up in the preferred list by dragging it with the mouse on a higher position in the list of JVMs available in the **Java Preferences** panel that is opened from **Applications** > **Utilities** > **Java** > **Java Preferences**.

Signature Verification Failed Error on a Resource from Documentum

Problem

When I try to open/edit a resource from Documentum, I receive the following error:

`signature verification failed: certificate for All-MB.jar.checksum not signed by a certification authority.`

Solution

The problem is that the certificates from the Java Runtime Environment 1.6.0_22 or later no longer validate the signatures of the UCF *JARS*.

Set the `-Drequire.signed.ucf.jars=false` parameter, as explained in the *Setting a Parameter in the Launcher Configuration File / Startup Script* topic.

Special Characters are Replaced with a Square in Editor

Problem

My file was created with other application and it contains special characters (such as é, ©, ®, etc.) Why does Oxygen XML Editor display a square for these characters when I open the file in Oxygen XML Editor?

Solution

You must set a font able to render the special characters in the ***Font*** *preferences*. If it is a text file you must also set *the encoding used for non XML files*. If you want to set a font that is installed on your computer but that font is not accessible in the **Font** preferences, this means the Java virtual machine is not able to load the system fonts (probably because it is not a True Type font). It is a problem of the Java virtual machine and a possible solution is to copy the font file in the `[JVM_DIR]/lib/fonts` folder. `[JVM_DIR]` is the value of the property *java.home* that is available in the **System properties** tab of the **About** dialog box that is opened from menu **Help** > **About**.

TocJS Transformation Does not Generate All Files for a Tree-Like TOC

Problem

The *TocJS* transformation of a *DITA map* does not generate all the files needed to display the tree-like table of contents.

Solution

To get a complete set of output files, follow these steps:

1. Run the *XHTML* transformation on the same *DITA map*. Make sure the output gets generated in the same output folder as for the *TocJS* transformation.
2. Copy the content of *`DITA-OT-DIR`*`/plugins/com.sophos.tocjs/basefiles` folder in the transformation output folder.
3. Copy the *`DITA-OT-DIR`*`/plugins/com.sophos.tocjs/sample/basefiles/frameset.html` file in the transformation's output folder.
4. Edit `frameset.html` file.
5. Locate element `<frame name="contentwin" src="concepts/about.html">`.
6. Replace `"concepts/about.html"` with `"index.html"`.

Topic References Outside the Main DITA Map Folder

Problem

Referencing a DITA topic, *map*, or binary resource (for example, image) that is located outside of the folder where the main *DITA map* is located leads to problems when publishing the content using the DITA Open Toolkit.

Solution

The DITA-OT does not handle it well when references are outside the directory where the published *DITA map* is found. By default, it does not even copy the referenced topics to the output directory.

To solve this, choose one of the following options:

- Create another *DITA map* that is located in a folder path above all referenced folders and reference from it the original *DITA map*. Then transform this *DITA map* instead.
- Edit the transformation scenario and in the **Parameters** tab edit the **fix.external.refs.com.oxygenxml** parameter. This parameter is used to specify whether or not the application tries to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. The allowed values are `false` and `true`. The default value is `false`.

  Important: The **fix.external.refs.com.oxygenxml** parameter is only supported when the DITA OT transformation process is started from Oxygen XML Editor.
- For PDF output, you can edit the transformation scenario and in the **Parameters** tab set the value of the **generate.copy.outer** parameter to 3. This parameter specifies whether to generate output files for content that is not located in or beneath the directory containing the DITA map file. By setting the value of this parameter to 3, the transformation scenario shifts the output directory so that it contains all output for the publication.

  Important: This method is recommended for transformation scenarios that use an external DITA-OT.

Wrong Highlights of Matched Words in a Search in User Manual

Problem

When I do a keyword search in the User Manual that is included with the Oxygen XML Editor application, the search highlights the wrong word in the text. Sometimes the highlighted word is several words after the matched word. What can I do to get correct highlights?

Solution

This does not happen when Oxygen XML Editor runs with a built-in Java virtual machine, that is a JVM that was installed by Oxygen XML Editor in a subfolder of the installation folder (for example, on Windows and Linux when installing Oxygen XML Editor with the installation wizard specific for that platform). When Oxygen XML Editor runs from an All Platforms installation, it uses whatever JVM was found on the host system, which may be incompatible with the JavaHelp indexer used for creating the built-in User Manual. Such a JVM may offset the highlight of the matched word with several characters, usually to the right of the matched word. To see the highlight exactly on the matched word, it is recommended to install the application with the specific installation wizard for your platform (available only for Windows and Linux).

XML Document Takes a Long Time to Open

Problem

Oxygen XML Editor takes a long time to open a document.

Solution

It takes longer to open an XML document if the whole content of your document is on a single line or if the document size is very large.

If the content is on a single line, you can speed up loading by selecting the ***Format and indent the document on open*** *option* (in the **Format** preferences page).

If the document is very large (above 30 MB), make sure that the value of the ***Optimize loading in the Text edit mode for files over*** *option* (in the **Open/Save** preferences page) is greater than the size of your document.

If that fails and you get an Out Of Memory error (**OutOfMemoryError**) you can *increase the memory available to Oxygen XML Editor.*

XSLT Debugger Is Very Slow

Problem

When I run a transformation in the **XSLT Debugger** *perspective* it is very slow. Can I increase the speed?

Solution

If the transformation produces HTML or XHTML output you should *disable rendering of output in the XHTML output view* during the transformation process. To view the XHTML output result do one of the following:

- Run the transformation in the **Editor** *perspective* and make sure the ***Open in Browser/System Application*** *option* is selected.
- Run the transformation in the **XSLT Debugger** *perspective*, save the text output area to a file, and use a browser application for viewing it (for example Firefox or Internet Explorer).

DITA Authoring and Publishing

20

Topics:

- *Working with DITA Maps*
- *Working with DITA Topics*
- *Working with Markdown Documents in DITA*
- *Working with Keys*
- *Reusing DITA Content*
- *Linking in DITA*
- *Publishing DITA Output*
- *DITA Profiling / Conditional Text*
- *DITA Open Toolkit Support*
- *DITA Specialization Support*
- *Master Files Support in DITA*
- *Metadata*
- *Migrating MS Office Documents to DITA*
- *DITA 1.3 Support*

DITA is an XML standard, an architectural approach, and a writing methodology, developed by technical communicators for technical communicators. It provides a standardised architectural *framework* for a common structure for content that promotes the consistent creation, sharing, and re-use of content.

Some of the benefits of using DITA include the following:

- **Flexibility** - DITA is a topic-based architecture and it offers flexibility in content organization.
- **Modularity** - DITA allows for content reuse that saves time and reduces the number of modifications.
- **Structured Authoring** - DITA offers a standardized, methodological approach that helps to reduce authoring time and improve consistency.
- **Single-Source Publishing** - DITA provides the ability to change content in one place and have the change propagate everywhere.
- **Multiple Output Formats** - DITA supports multiple types of output.
- **Inheritance** - The DITA inheritance model makes it easy to specialize topics or elements within topics and you only have to define how the element is different from its immediate ancestor.
- **Process Automation** - DITA offers various ways to automate processes, such as with index or glossary production, output delivery, validation, and more.
- **Specialization** - DITA allows you to define your own information types and semantic elements/attributes to suit the needs of your particular content model.
- **Multi-Lingual** - DITA is a translation-friendly structure that supports numerous languages and text encodings.
- **Conditional Profiling** - DITA supports conditional text processing and profiling to filter content in the publishing stage.

This chapter is designed to be a guide to help content authors who use DITA. It also presents the Oxygen XML Editor features that are specific to working with DITA documents and concepts.

DITA Resources

For more general information and technical details about working with DITA, refer to the following resources:

- *The DITA Specifications*.
- *The DITA Style Guide Best Practices for Authors*.

- Various sample DITA topics and maps can be found in the *[OXYGEN_INSTALL_DIR]*/samples/dita folder.

  Related Information:
  DITA Topics Document Type (Framework) on page 1003
  DITA Map Document Type (Framework) on page 1013

Working with DITA Maps

In the DITA standard architecture you create documents by collecting topics into maps.

DITA Maps

A *DITA map* organizes a set of topics into a hierarchy. In most output formats, the structure of the map becomes the structure of the table of contents. Oxygen XML Editor provides support for *creating* and *managing DITA maps* through the ***DITA Maps Manager***. There are also specialized types of *DITA maps*, such as a *bookmap*, which is intended for creating the structure of a book.

Submaps

You do not have to create an entire publication using a single map. It is generally good practice to break up a large publication into several smaller *submaps* that are easier to manage. You can reuse submaps in multiple publications by including them in each of the main maps. The ***DITA Maps Manager*** provides support for easily creating and managing submaps.

Opening a DITA Map

There are several ways to open a *DITA map* and you can choose to open it in the ***DITA Maps Manager*** or in the XML Editor. Use any of the following methods to open a map:

- To open a submap in its own tab in the **DITA Maps Manager**, simply double-click it (or right-click it and select **Open**).
- To open a map in the XML editor from the **DITA Maps Manager**, right-click it and select **Open Map in Editor**.
- Drag a *DITA map* file from your system browser and drop it in the XML editor. This will open the map in the editor.
- If you open a file with the `.ditamap` or `.bookmap` extension (from the ***Project*** *view* or a system browser), a dialog box is opened that offers you the choice of opening it in the XML editor or in the **DITA Maps Manager**.

  Note: If you select the **Do not show the dialog again** option, it will always be opened in the method that you choose and you will not be asked in the future. However, you can reset this by selecting **Always ask** for the ***When opening a map*** *option in the* ***DITA*** *preferences page*.
- To open a map in the **DITA Maps Manager**, you can right-click a map file in the ***Project*** *view* and select **Open with** > **DITA Maps Manager**.
- If you have a *DITA map* file open in the XML editor, you can open it in the **DITA Maps Manager** by right-clicking the title tab and selecting **Open in DITA Maps Manager View**.

Chunking DITA Maps

By default, many output types place a single topic on each output page. In some cases you may want to *output multiple topics as a single output page (also known as chunking)*. To support this, Oxygen XML Editor provides an ***Edit Properties*** *dialog box* that allows you to easily configure the attributes of a topic to control how your table of contents and topics are rendered in the output.

Validating a Map

You should *validate your maps* to make sure that the individual topics are valid and that the relationships between them are working. Oxygen XML Editor provides a validation function for *DITA maps* that performs a comprehensive validation of a map and its topics.

For more information about DITA editing, watch our video demonstration:

Related Information:

DITA Map Document Type (Framework) on page 1013

DITA Map Author Mode Actions on page 1014

DITA Maps Manager

Oxygen XML Editor provides a view for managing and editing *DITA maps*. The **DITA Maps Manager** view presents a *DITA map* as a Table of Contents. It allows you to navigate the topics and maps, make changes, and apply transformation scenarios to obtain various output formats. By default, it is located to the left of the main editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

The **DITA Maps Manager** includes a variety of useful actions to help you edit and organize the structure of your *DITA maps* and topics. The actions that are available and their functions depend on the type of nodes that are selected in the **DITA Maps Manager**. If you select multiple sibling nodes, the result of the actions will be applied to all the selected nodes. If you select multiple nodes that are not on the same hierarchical level, the actions will be applied to the parent node and the child nodes will inherit certain attributes from the parent node.

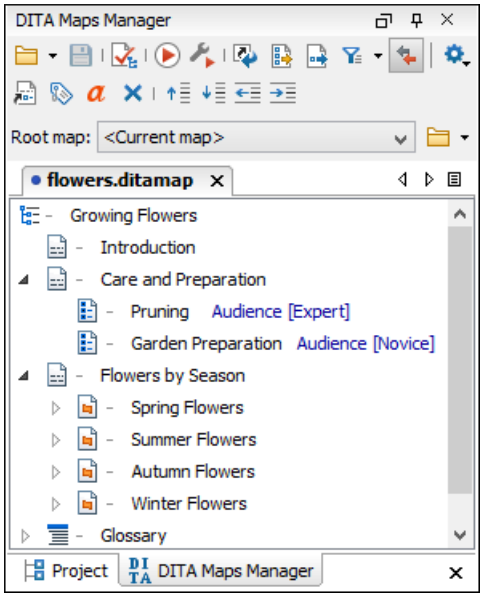


Figure 839: DITA Maps Manager View

Opening Maps in the DITA Maps Manager

The **DITA Maps Manager** view supports multiple open maps at the same time, with each one presented in its own tab. To open a *DITA map* in the **DITA Maps Manager**, use any of the following methods:

- To open a submap in its own tab, simply double-click it (or right-click it and select **Open**).
- If you open a file with a `.ditamap` or `.bookmap` extension (from the ***Project** view* or a system browser), a dialog box is opened that offers you the choice of opening it in the **DITA Maps Manager** or the XML editor.

  Note: If you select the **Do not show the dialog again** option, it will always be opened in the method that you choose and you will not be asked in the future. However, you can reset this by selecting **Always ask** for the ***When opening a map** option in the **DITA** preferences page*.
- Right-click a map file in the ***Project** view* and select **Open with** > **DITA Maps Manager**.
- If you have a *DITA map* file open in the XML editor, you can right-click the title tab and select **Open in DITA Maps Manager View**.

If your map references other *DITA maps*, they will be shown, expanded, in the **DITA Maps Manager** view and you will be able to navigate their content. To edit the submaps and their content, you need to open each referenced map separately.

Drag and Drop in the DITA Maps Manager

You can move topics or nodes within the same map, or other maps, by dragging and dropping them into the desired position. You can arrange the nodes by dragging and dropping one or more nodes at a time. You can arrange multiple topics by dragging them while pressing the **Ctrl** or **Shift** key. Drop operations can be performed before, after, or as child of the targeted node.

Drag and drop operations include:

Copy

Select the nodes you want to copy and start dragging them. Before dropping them in the appropriate place, press and hold the **Ctrl** key. The mouse pointer changes to a symbol to indicate that a copy operation is being performed.

Move

Select the nodes you want to move and drag and drop them in the appropriate place.

Promote (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))/Demote (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))

You can move nodes between child and parent nodes by using the **Promote** (**Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X)**) and **Demote** (**Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X)**) operations.

DITA Maps Manager Toolbar

The toolbar includes the following actions (also available in the**DITA Maps** menu) and their availability depend on the nodes that are selected:

Note: If multiple nodes are selected, the availability of the actions depends on the nodes that are selected.

Open Drop-down Menu

You can use this drop-down menu to open new *DITA maps* or to reopen recently viewed maps. The drop-down menu contains the following:

- List of recently viewed *DITA maps* that can be selected to reopen them.
- **Clear history** - Clears the history list of the recently viewed *DITA maps*.
- **Open** - Allows you to open the map in the ***DITA Maps Manager*** *view*. You can also open a map by dragging it from the file system explorer and dropping it into the ***DITA Maps Manager*** *view*.
- **Open URL** - Displays the **Open URL** dialog box that allows you to access any resource identified through a URL (defined by a protocol, host, resource path, and an optional port). The following actions are available in this drop-down menu:
  - **Browse for local file** - Opens a local file browser dialog box, allowing you to select a local *DITA map*.
  - **Browse for remote file** - Displays the ***Open URL*** *dialog box* that allows you to open a remotely stored *DITA map*.
  - **Browse for archived file** - Displays the ***Archive Browser*** that allows you to browse the content of an archive and choose a *DITA map*.
  - **Browse Data Source Explorer** - Opens the ***Data Source Explorer*** that allows you to browse the data sources defined in the *Data Sources preferences page*.

    Tip: You can open the **Data Sources** preferences page by using the **Configure Database Sources** shortcut from the **Open URL** dialog box.
  - **Search for file** - Displays the ***Open/Find Resource*** *dialog box* that allows you to search for a *DITA map*.

Save (Ctrl (Meta on Mac OS)+S)

Saves the current *DITA map*.

Validate and Check for Completeness

Checks the validity and integrity of the map.

Apply Transformation Scenario(s)

Applies the DITA Map transformation scenario that is associated with the current map.

Configure Transformation Scenario(s)

Opens the ***Configure Transformation Scenarios(s)*** *dialog box* where you can edit or create transformation scenarios or *associate a DITA Map transformation scenario* with the current map.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced documents. This action is useful when the referenced documents are modified externally. When they are modified and saved from Oxygen XML Editor, the *DITA map* is updated automatically.

Open Map in Editor with Resolved Topics

Opens the *DITA map* in the main editor area with content from all topic references, expanded in-place. Content from the referenced topics is presented as read-only and you have to use the contextual menu action **Edit Reference** to open the topic for editing.

Tip: If you want to print the expanded content, you should consider changing the **Styles** drop-down to **+ Print ready**.

Open Map in Editor

For complex operations that cannot be performed in the simplified **DITA Maps Manager** view (for instance, editing a relationship table) you can open the map in the main editing area.

Note: You can also use this action to open referenced *DITA maps* in the **Editor**.

Profiling/Conditional Text Drop-down Menu

This drop-down menu contains the following actions:

- **Show Profiling Colors and Styles** - Select this option to turn on conditional styling. To configure the colors and styles *open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to **Editor** > **Edit modes** > **Author** > **Profiling/Conditional Text** > **Colors and Styles**.
- **Show Profiling Attributes** - Select this option to display the values of the profiling attributes at the end of the titles of topic references. When selected, the values of the profiling attributes are displayed in both the **DITA Maps Manager** view and in the **Author** view.
- **Show Excluded Content** - Controls if the content filtered out by a particular condition set is hidden or grayed-out in the editor area and in the ***Outline*** and **DITA Maps Manager** views. When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.
- **Profiling Settings** - Opens the preferences page for adding and editing the profiling conditions that you can apply in the **DITA Maps Manager** view and the **Author** mode editing pane. When a *profiling condition set* is applied, the keys that are defined in the *DITA map* are gathered by filtering out the excluded content.

Link with Editor

Toggles the synchronization between the file path of the current editor and the selected topic reference in the **DITA Maps Manager** view.

Note: This button is toggled off automatically when you move to a **Debugger** *perspective*.

Settings

Show extended toolbar

Toggles whether or not the extended toolbar will be displayed in the **DITA Maps Manager** toolbar.

Show root map toolbar

Toggles whether or not the ***Root map*** *option* will be displayed in the **DITA Maps Manager** toolbar.

Show topic titles

Toggles how topics are presented in the **DITA Maps Manager**. If selected, the title of each topic is shown. Otherwise, the file path (value of the `href` attribute) for each topic is shown.

Root map

Specifies a master *DITA map* (*root map*) that Oxygen XML Editor uses to define a hierarchical structures of submaps and to establish a *key space* that defines the keys that are propagated throughout the entire map structure. For more information, see *Selecting a Root Map* on page 1793.

Browse Drop-down menu

You can use this drop-down menu to browse for *root maps* with the following choices:

- **Browse for local file** - Opens a local file browser dialog box, allowing you to select a local *root map*.
- **Browse for remote file** - Displays the ***Open URL*** *dialog box* that allows you to select a remotely stored *root map*.
- **Browse for archived file** - Displays the ***Archive Browser*** that allows you to browse the content of an archive and choose a *root map*.
- **Browse Data Source Explorer** - Opens the ***Data Source Explorer*** that allows you to browse the data sources defined in the *Data Sources preferences page*.

  Tip: You can open the **Data Sources** preferences page by using the **Configure Database Sources** shortcut from the **Open URL** dialog box.
- **Search for file** - Displays the ***Find Resource*** *dialog box* to search for a *root map*.

The following additional actions are displayed in the toolbar when the **Show extended toolbar** option is selected in the **Settings** menu:

Insert Topic Reference

Opens *the* ***Insert Reference*** *dialog box* that allows you to insert references to targets such as topics, maps, topic sets, or key definitions.

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see *Edit Properties Dialog Box* on page 1805.

Edit Attributes

Opens a small in-place editor that allows you to edit the attributes of a selected node. You can find more details about this action in the *Attributes View in Author Mode* on page 268 topic.

Delete

Deletes the selected node.

Move Up

Moves the selected node up within the *DITA map* tree.

Move Down

Moves the selected node down within the *DITA map* tree.

Promote(Alt + LeftArrow)

Moves the selected node up one level to the level of its parent node.

Demote(Alt + RightArrow)

Moves the selected node down one level to the level of its child nodes.

Contextual Menu of the DITA Maps Manager

Root Map

The following actions can be invoked from the contextual menu on the *root map* of an opened *DITA map* (many of them are also available in the**DITA Maps** menu):

Open Map in Editor

For complex operations that cannot be performed in the simplified **DITA Maps Manager** view (for instance, editing a relationship table) you can open the map in the main editing area.

Open Map in Editor with Resolved Topics

Opens the *DITA map* in the main editor area with content from all topic references, expanded in-place. Content from the referenced topics is presented as read-only and you have to use the contextual menu action **Edit Reference** to open the topic for editing.

Export DITA Map

Opens a dialog box that allows you to choose a destination for exporting the *DITA map*. It also includes a **Export as Zip archive** option that allows you to package the *DITA map* as a zip archive.

Find Unreferenced Resources

Allows you to search for orphaned resources that are not referenced in the *DITA maps*.

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see *Edit Properties Dialog Box* on page 1805.

Fast Create Topics

Opens the ***Fast Create Topics*** *dialog box* that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map*.

Append Child submenu

Container sub-menu for a number of actions that create a map node as a child of the currently selected node:

- **New** - Opens a dialog box that allows you to configure some options for *inserting a new topic*.
- **Reference** - Inserts a reference to a topic file. You can find more details about this action in the *Inserting References* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the *Inserting References* topic.
- **Key Reference** - Opens an ***Insert Key Definition*** *dialog box* that allows you to insert a key reference.
- **Key Reference with Keyword** - Opens a simplified ***Insert Key Definition*** *dialog box* that allows you to define a key and a value inside a *keyword*.
- A set of actions that open the ***Insert Reference*** *dialog box* that allow you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

Search References

Searches all references to the current topic in the entire *DITA map*.

Refactoring submenu

The following actions are available from this submenu:

Convert Markdown to DITA Topic (Available for Markdown documents)

Opens a dialog box that allows you to configure options for *converting the Markdown document into a DITA topic*.

Rename resource

Allows you to *change the name of a resource linked in the edited DITA map*.

Move resource

Allows you to *change the location on disk of a resource linked in the edited DITA map*.

XML Refactoring

Opens *the XML Refactoring tool wizard* that presents refactoring operations to assist you with managing the structure of your XML documents.

Other XML Refactoring Actions

For your convenience, the last 5 *XML Refactoring tool operations* that were finished or previewed will also appear in this submenu.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace content across multiple files.

Check Spelling in Files

Allows you to *spell check multiple files*.

Paste

Allows you to paste content from the clipboard into the *DITA map*.

Paste Before

Pastes the content of the clipboard (only if it is a part of the *DITA map*) before the currently selected *DITA map* node.

Paste After

Pastes the content of the clipboard (only if it is a part of the *DITA map*) after the currently selected *DITA map* node.

Expand All

Allows you to expand the entire *DITA map* structure.

Collapse All

Allows you to collapse the entire *DITA map* structure.

Child Nodes

The following actions are available when the contextual menu is invoked on a child node of a *DITA map* (submaps need to be opened in the **DITA Maps Manager** to access these actions since they are in a read-only state in the parent map):

Note: If multiple nodes are selected, the availability of the actions depends on the nodes that are selected.

Open

Opens in the editor the resources referenced by the nodes that you select.

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see *Edit Properties Dialog Box* on page 1805.

Fast Create Topics

Opens the ***Fast Create Topics*** *dialog box* that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map*.

Append Child submenu

Container sub-menu for a number of actions that create a map node as a child of the currently selected node:

- **New** - Opens a dialog box that allows you to configure some options for *inserting a new topic*.
- **Reference** - Inserts a reference to a topic file. You can find more details about this action in the *Inserting References* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the *Inserting References* topic.
- **Key Reference** - Opens an ***Insert Key Definition*** *dialog box* that allows you to insert a key reference.
- **Key Reference with Keyword** - Opens a simplified ***Insert Key Definition*** *dialog box* that allows you to define a key and a value inside a *keyword*.

- A set of actions that open the ***Insert Reference*** *dialog box* that allow you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

Insert Before submenu

Container sub-menus for a number of actions that create a map node as a sibling of the currently selected node, above the current node in the map:

- **New** - Opens a dialog box that allows you to configure some options for *inserting a new topic*.
-  **Reference** - Inserts a reference to a topic file. You can find more details about this action in the *Inserting References* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the *Inserting References* topic.
- **Key Reference** - Opens an ***Insert Key Definition*** *dialog box* that allows you to insert a key reference.
- **Key Reference with Keyword** - Opens a simplified ***Insert Key Definition*** *dialog box* that allows you to define a key and a value inside a *keyword*.
- A set of actions that open the ***Insert Reference*** *dialog box* that allow you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

Insert After submenu

Container sub-menus for a number of actions that create a map node as a sibling of the currently selected node, below the current node in the map:

- **New** - Opens a dialog box that allows you to configure some options for *inserting a new topic*.
-  **Reference** - Inserts a reference to a topic file. You can find more details about this action in the *Inserting References* topic.
- **Reference to the currently edited file** - Inserts a reference to the currently edited file. You can find more details about this action in the *Inserting References* topic.
- **Key Reference** - Opens an ***Insert Key Definition*** *dialog box* that allows you to insert a key reference.
- **Key Reference with Keyword** - Opens a simplified ***Insert Key Definition*** *dialog box* that allows you to define a key and a value inside a *keyword*.
- A set of actions that open the ***Insert Reference*** *dialog box* that allow you to insert various reference specializations (such as **Anchor Reference**, **Glossary Reference**, **Map Reference**, **Navigation Reference**, **Topic Group**, **Topic Head**, **Topic Reference**, **Topic Set**, **Topic Set Reference**).

 **Search References**

Searches all references to the current topic in the entire *DITA map*.

Refactoring submenu

The following actions are available from this submenu:

Convert Markdown to DITA Topic (Available for Markdown documents)

Opens a dialog box that allows you to configure options for *converting the Markdown document into a DITA topic*.

Rename resource

Allows you to *change the name of a resource linked in the edited DITA map*.

Move resource

Allows you to *change the location on disk of a resource linked in the edited DITA map*.

 **XML Refactoring**

Opens *the XML Refactoring tool wizard* that presents refactoring operations to assist you with managing the structure of your XML documents.

Other XML Refactoring Actions

For your convenience, the last 5 *XML Refactoring tool operations* that were finished or previewed will also appear in this submenu.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace content across multiple files.

Check Spelling in Files

Allows you to *spell check multiple files*.

Cut

Deletes the currently selected node and copies it to the clipboard.

Copy

Copies the currently selected node to the clipboard.

Paste

Allows you to paste content from the clipboard into the *DITA map*.

Paste Before

Pastes the content of the clipboard (only if it is a part of the *DITA map*) before the currently selected *DITA map* node.

Paste After

Pastes the content of the clipboard (only if it is a part of the *DITA map*) after the currently selected *DITA map* node.

Delete

Deletes the currently selected node from the *DITA map*.

Organize

Allows you to organize the *DITA map* with the several submenu actions:

- **Move Up** - Moves the selected node up within the *DITA map* tree.
- **Move Down** - Moves the selected node down within the *DITA map* tree.
- **Promote**(**Alt + LeftArrow**) - Moves the selected node up one level to the level of its parent node.
- **Demote**(**Alt + RightArrow**) - Moves the selected node down one level to the level of its child nodes.

Expand All

Allows you to expand the entire *DITA map* structure.

Collapse All

Allows you to collapse the entire *DITA map* structure.

Other Nodes

The following actions are available when the contextual menu is invoked from a *map* node that is not an immediate child node of the *root map* or other special nodes (such as relationship tables):

Note: If multiple nodes are selected, the availability of the actions depends on the nodes that are selected.

Open

Opens in the editor the resources referenced by the nodes that you select.

Open Map in Editor (available when invoking on a submap)

Opens the currently selected *DITA map* in the editor.

Open parent DITA map (available when invoking on a topic reference or a submap reference)

Opens the parent *DITA map* of the currently selected reference in the **DITA Maps Manager**.

Edit Attributes (only available for relationship table nodes)

Opens a small in-place editor that allows you to edit the attributes of a selected node. You can find more details about this action in the *Attributes View in Author Mode* on page 268 topic.

Edit Profiling Attributes (only available for relationship table nodes)

Allows you to change the *profiling attributes* defined on the selected node.

Search References

Searches all references to the current topic in the entire *DITA map*.

Refactoring submenu

The following actions are available from this submenu:

Convert Markdown to DITA Topic (Available for Markdown documents)

Opens a dialog box that allows you to configure options for *converting the Markdown document into a DITA topic*.

Rename resource

Allows you to *change the name of a resource linked in the edited DITA map*.

Move resource

Allows you to *change the location on disk of a resource linked in the edited DITA map*.

XML Refactoring

Opens *the XML Refactoring tool wizard* that presents refactoring operations to assist you with managing the structure of your XML documents.

Other XML Refactoring Actions

For your convenience, the last 5 *XML Refactoring tool operations* that were finished or previewed will also appear in this submenu.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace content across multiple files.

Check Spelling in Files

Allows you to *spell check multiple files*.

Copy

Copies the currently selected node to the clipboard.

Expand All

Allows you to expand the entire *DITA map* structure.

Collapse All

Allows you to collapse the entire *DITA map* structure.

For more information about the **DITA Maps Manager** view and many of its features, watch our video demonstration:

Find/Replace in Multiple Files on page 685

Creating a Map

To create a *DITA map*, *subject scheme map*, *bookmap*, or other types of *DITA maps*, follow these steps:

1. Use the ***New Document*** *wizard* to start creating your map.

   Tip: If you want the *map* to be a submap, you can create it the same way by right-clicking the place in the current map where you want to add it (in the ***DITA Maps Manager***) and selecting **New** from the **Append Child**, **Insert Before**, or **Insert After** submenu.
2. Select one of the **DITA Map** templates from the **Framework templates** folder.
3. Click the **Create** button.

4. Select whether you want to open the map in the ***DITA Maps Manager*** or the **Editor**.
5. Save the map using the **Save** button on the toolbar of the ***DITA Maps Manager*** *view*.

Related Information:

Customizing Profiling Values with a Subject Scheme Map on page 1917

Managing DITA Maps on page 1794

Selecting a Root Map

Oxygen XML Editor allows you to select a *root map* (a master *DITA map*) that defines a hierarchical structure of submaps and establishes a *key space* that defines the keys used in all the other *DITA maps* and topics in the project. Specifying the correct *root map* helps to prevent validation problems when you work with `keyrefs` and also acts as the foundation for content completion. All the *keys* that are defined in a *root map* are available in the submaps that are contained within the *root map*.

There are several ways to select or change the *root map*:

- The easiest method is to use the ***Root map*** *drop-down menu* in the ***DITA Maps Manager*** toolbar to select the appropriate *root map*.
- If you insert a *key reference* using the **Cross Reference** action from the **Link** drop-down menu (from the toolbar or **Link** submenu of the contextual menu) and keys are not gathered from the expected *DITA map*, you can change the *root map* by using the **Change Root Map** link in the **Choose Key** dialog box that is opened when you click the **Choose Key Reference** button.
- If you insert a *content key reference* or *key reference* using the **Reuse Content** action (from the toolbar, **DITA** menu, or **Reuse** submenu of the contextual menu) and keys are not gathered from the expected *DITA map*, you can change the *root map* by using the **Change Root Map** link in the **Choose Key** dialog box that is opened when you click the **Choose Key Reference** button.

For more information about the DITA *root map* support, watch our video demonstration:

Creating DITA Submaps

You can break up a large *DITA map* into more manageable pieces by creating submaps. A submap is simply a *DITA map* that is included by another *DITA map*. There is no separate markup for a submap.

For example, if you are creating a book, you might use one submap for each chapter of the book. If you are reusing a set of topics in multiple publications, you might collect them into a map and reuse the map as a submap in multiple other maps, rather than referencing the topics individually from the new maps.

You add a submap to a map the same way that you would *add a new topic or insert an exiting topic into a map*, except you choose a map rather than a topic to create or add. When adding a submap to a map make sure that you use a `mapref` element or a `topicref` element with the `format` attribute set to `ditamap`. In most cases, Oxygen XML Editor takes care of this for you.

Adding a Submap to a Map

To add a submap to a map:

1. Right-click the place in the current map where you want to add the new submap.
2. To insert the submap as a child of the selected node, select **Append Child** > **New**. To insert the submap as a sibling to the current node, select **Insert After** > **New** or **Insert Before** > **New**.

   Step Result: This opens a ***New*** *file template dialog box* that allows you to select the type of document and assists you with naming it.
3. Select the type of map in one of the folders inside the **DITA Map** folder and give it a name (the file type should be `.ditamap`).
4. Click **Create** to insert the submap.

You can also manage and move submaps the same as you would with topics. For more information, see *Managing DITA Maps* on page 1794.

Creating a Bookmap in DITA

If you want to create a traditional book in DITA, you can use a *bookmap* to organize your topics into a book. A DITA *bookmap* is a specialized type of map, intended for creating output that is structured like a book. A *bookmap* allows you to add book-specific elements such as `frontmatter`, `part`, `chapter`, `appendix`, and `backmatter` to the map. How these book-specific elements are processed for publication is up to the processing script for each media. See the *DITA documentation* for details.

You can find additional support for creating books in DITA in the DITA for Publishers plugin, which is included with Oxygen XML Editor.

To create a book in DITA using a *bookmap*, follow these steps:

1. Create a new *bookmap* (**File** > **New** > **Framework templates** > **DITA Map** > **map** > **Bookmap**). If you want the *bookmap* to be a submap, you can create it the same way by right-clicking the place in the current map where you want to add it (in the ***DITA Maps Manager***) and selecting **New** from the **Append Child**, **Insert Before**, or **Insert After** submenus.
2. Create the structure of your book by adding the appropriate book sections and defining containers for chapters and any appendices. To add sections to a *bookmap*, or children to a section, right-click the *bookmap* or section icon and choose any of the reference actions in the **Append child** menu. The selections offered in the menu will adjust depending on the element they are applied to. Consult the *DITA documentation* to fully understand the structure of a DITA *bookmap* and where to create each element.
3. Create special elements such as an *index* and *table of contents*. The index and table of contents will be generated by the build process, based on the content of the map and the topics it points to.
4. *Add topics* to your chapters to add content to your book. You may find it easier to manage if you *use submaps* to create the content of your chapters. This keeps your *bookmap* from becoming long and difficult to manage.

Managing DITA Maps

You may want to manage your *DITA maps* in a variety of ways, including:

- Change the order and nesting of topics in a map.
- Add topics to a map.
- Insert various types of references in a map.
- Find, move, or rename resources in a map.
- Change other properties of the items in a map.
- Use the Edit Properties dialog box to manage attributes, keys, metadata, or add profiling to any section of a map.

This section includes various topics that describe how you can manage *DITA maps* and resources.

For more information about the **DITA Maps Manager** view and many of its features, watch our video demonstration:

Change the Order of Topics in DITA Maps

You can change the order and nesting of the topics in a map in several ways:

- By dragging and dropping topics within the ***DITA Maps Manager***.
- By highlighting a topic in the ***DITA Maps Manager***, holding down the **Alt** key, and pressing the arrow keys.
- By showing the extended ***DITA Maps Manager*** toolbar (press the **Settings** icon on the ***DITA Maps Manager*** toolbar and select the extended toolbar) and then using the node moving buttons () on the toolbar to move topics around in the map.

To understand how to organize topics in a *DITA map* using the ***DITA Maps Manager***, you can examine and experiment with the sample map called `flowers.ditamap`, located in the *`[OXYGEN_INSTALL_DIR]`*`/samples/dita` folder.

Adding Topics to a DITA Map

When you are working in DITA, there are several approaches that you can use to create topics and maps. You can start by first creating topics and then assembling your finished topics into one or more documents by creating one or more maps, or you can start by creating a map and then adding new topics to it as you work.

The topics-first approach is generally more appropriate if you intend to do a lot of content reuse, as it encourages you to think of each topic as an independent unit that can be combined with other topics in various ways. The map-first approach will be more familiar to you if you are used to creating books or manuals as a whole. Oxygen XML Editor supports both approaches.

A *DITA map* organizes content hierarchically, so you can add a topic as a child of the map root element or as a child or sibling of any item already in the map. Therefore, the first step to adding a topic to a map is always to choose the place it will be inserted into the map.

Adding Existing Topics to a Map

At the XML-level, a topic is added to a map by adding a reference to the map that points to the topic. There are a variety of reference types that you can use. The default type is the `topicref` element. See the *DITA documentation* for the full range of reference elements and their uses. Oxygen XML Editor provides several tools for inserting reference elements into a map:

Using the Insert Reference Dialog Box

The ***Insert Reference** dialog box* allows you to create various reference types and configure the most commonly used attributes. You can open the **Insert Reference** dialog box with any of the following methods:

- Right-click an item in the current map where you want to add the reference, select **Append Child**, **Insert Before**, or **Insert After** and select the type of reference to enter.
- If the topic you want to add is currently open in the editor, you can right-click an item in the current map where you want to add the reference and select **Reference to the currently edited file**.
- Selecting an item in the map and click the  **Insert Reference** button from the ***DITA Maps Manager*** toolbar.
- Select  **Insert Reference** from the **DITA Maps** menu.

Dragging and Dropping a File into the DITA Maps Manager

You can add a topic to a *DITA map* by dragging and dropping the file into the ***DITA Maps Manager***. You can drag and drop files from any of the following:

- Your OS file system explorer.
- The ***Project** view*.
- The ***Open/Find Resource** view*.

Adding topics this way will not open the **Insert Reference** dialog box, but you can adjust all the same properties by invoking the contextual menu from the topic and selecting **Edit Properties**.

Adding a New Topic to a Map

To add a new topic to a map, follow these steps:

1. In the ***DITA Maps Manager***, right-click the node in the current map where you want to add the new topic.
2. Select one of the following actions:

- **Append Child** > **New** - Select this action to insert the new topic as a child of the selected node. This action opens a ***New** file dialog box* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
- **Insert Before** > **New** - Select this action to insert the new topic as a sibling to the current node, before it. This action opens a ***New** file dialog box* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
- **Insert After** > **New** - Select this action to insert the new topic as a sibling to the current node, after it. This action opens a ***New** file dialog box* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.

- **Duplicate** - Select this action to create a copy of the selected topic and insert it as a sibling. This action opens a dialog box that allows you to choose the file name and location for the newly created copy of the topic. After you have selected the name and path for your new topic, click **OK**.

Step Result: The new topic is now referenced (as a `topicref`) in the *DITA map* at the location where you inserted it and the new topic is opened in the editor.

3. Save the *DITA map*.

Adding Multiple Skeleton Topics at Once

Oxygen XML Editor includes a feature in the ***DITA Maps Manager*** that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map*.

To access this feature, right-click a node in the **DITA Maps Manager** where you want the new topics to be inserted and select **Fast Create Topics**. This opens the **Fast Create Topics** dialog box where you can configure the structure for the new topics.

For more information, see *Fast Create Multiple DITA Topics* on page 1822.

Adding Multiple References to the Same Topic in a Map

Oxygen XML Editor allows you to reuse entire topics by adding multiple references to the same topic in a *DITA map*. Whenever multiple references to the same topic are detected in the context of the current map in the ***DITA Maps Manager***, an indicator will appear in the top-right corner of the **Author** mode editor that shows the number of times the topic is referenced in the *DITA map*. It also includes navigation arrows that allow you to jump to the next or previous reference.

Remove Topics from a Map

You can remove topics from a map in a number of ways. Some ways to remove a topic from a map include:

- Highlight the topic and press **Delete** or **Backspace**.
- Highlight the topic and click the **Delete** button on the ***DITA Maps Manager*** extended toolbar.

Fast Create Multiple DITA Topics on page 1822

Moving and Renaming Resources

You can move or rename resources on disk directly from Oxygen XML Editor and you have the option of updating all the references to the moved or renamed resources. For DITA resources (such as topics and maps), you can do this from the ***DITA Maps Manager*** *view*. For non-DITA resources (such as folders, images, html files, audio, video, text files, Markdown documents), you can do this from the ***Project*** *view*.

Moving or Renaming DITA Resources (Topics or Maps)

To move or rename normal DITA resources (such as topics or maps), use one of the following actions available in the **Refactoring** submenu of the contextual menu when invoked on the resource in the ***DITA Maps Manager*** *view*:

Refactoring > Move resource

This action allows you to change the location of a resource linked in the edited *DITA map*, using the **Move resource** dialog box. This dialog box contains the following options:

- **Destination** - Specifies the target location of the edited resource.
- **File name** - Allows you to change the name of the edited resource.
- **Update references** - Select this checkbox to update all references of the file in the edited *DITA map* and in the files referenced from the *DITA map*, preserving the *completeness* of the *DITA map*.
- **Preview** - Select this button to display a preview of the changes Oxygen XML Editor is about to make.
- **Move** - Moves the edited resource in the target location on disk.
- **Cancel** - Cancels the **Move resource** operation. No changes are applied.

Refactoring > Rename resource

This action allows you to change the name of a resource linked in the edited *DITA map*, using the **Rename resource** dialog box. This dialog box contains the following options:

- **New name** - Presents the current name and allows you to change it.
- **Update references** - Select this checkbox to update all references of the file in the edited *DITA map* and in the files referenced from the *DITA map*, preserving the *completeness* of the *DITA map*.
- **Preview** - Select this button to display a preview of the changes Oxygen XML Editor is about to make.
- **Rename** - Executes the **Rename resource** operation.
- **Cancel** - Cancels the **Rename resource** operation. No changes are applied.

Note: If a *root DITA map* is not defined, the move and rename actions are executed in the context of the current *DITA map*.

Moving or Renaming Non-DITA Resources and Updating the References to Them

To move or rename non-DITA resources (such as folders, images, html files, audio, video, text files, Markdown documents), you can simply follow the procedures described in *Moving/Renaming Resources in the Project View* on page 463. However, this approach will not give you the option to update the references to the moved or renamed resources.

To perform move or rename operation on non-DITA resources while also updating all the references to them, use the following sets of procedures:

1. Enable *Master Files* support and add your *root DITA map* to the *Master Files* folder by following the procedure found here: *How to Enable Master Files Support in DITA* on page 1928.
2. Move or rename resources and update the references to them by following the procedure found here: *Moving or Renaming Non-DITA Resources and Updating the References to Them* on page 1929.

Finding Resources Not Referenced in DITA Maps on page 1797

Finding Resources Not Referenced in DITA Maps

Over the course of time large projects can accumulate a vast amount of resources from a variety of sources. Especially in organizations with a large number of content authors or complex project structures, organizing the project resources can become a challenge. Over time a variety of actions can cause resources to become orphaned from *DITA maps*. To assist you with organizing project resources, Oxygen XML Editor includes an action, **Find Unreferenced Resources**, that searches for orphaned resources that are not referenced in *DITA maps*.

To perform this search, open the *DITA map* in the ***DITA Maps Manager***, invoke the contextual menu on the *DITA map*, and select **Find Unreferenced Resources**. This action can also be selected from the **DITA Maps** menu. This action opens the **Find Unreferenced Resources** dialog box.

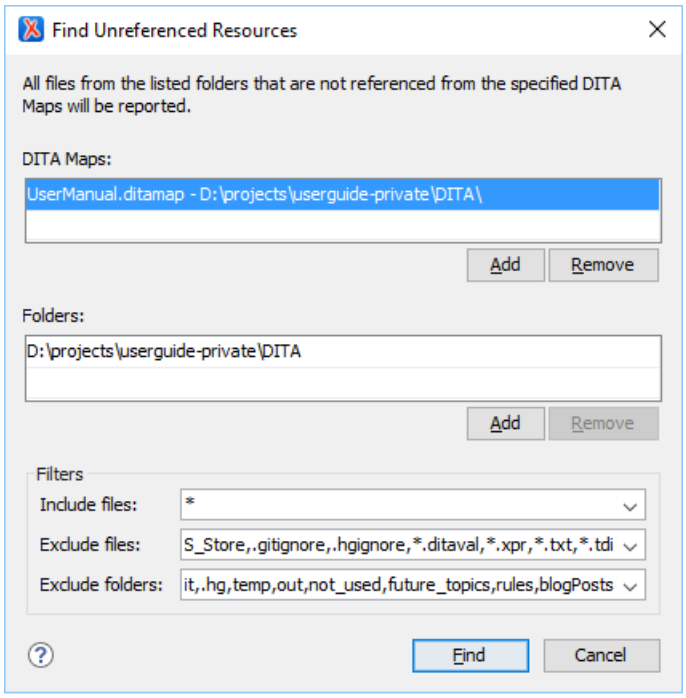

Figure 840: Find Unreferenced Resources Dialog Box

The **Find Unreferenced Resources** dialog box includes the following options:

- **DITA Maps** - Provides a list of *DITA maps* to be included in the search and allows you to **Add** maps to the list or **Remove** them.
- **Folders** - Provides a list of folders to be included in the search and allows you to **Add** or **Remove** specific folders.
- **Filters** - Provides three combo boxes that allow you to filter the search to include or exclude certain files or folders:
  - **Include files** - Allows you to filter specific files to include in the search.
  - **Exclude files** - Allows you to filter specific files to exclude from the search.
  - **Exclude folders** - Allows you filter specific folders to exclude from the search.

    Note: In any of the filter combo boxes you can enter multiple filters by separating them with a comma and you can use the *?* and *** wildcards. Use the drop-down arrow to select a previously used filter pattern.

When you click the **Find** button, if the search operation finds unreferenced resources, they are displayed in the **Results** panel at the bottom of the editor. If you want to delete an unreferenced resource, you can right-click its result and select **Remove from Disk**.

Inserting References in DITA Maps

A *DITA map* may contain various types of references. The targets of the references can be a variety of references, such as chapters, maps, topics, topic sets, or key definitions. You can insert references to such targets with the ***Insert Reference** dialog box*.

This section explains how to insert and configure references (such as topic references, topic groups, topic headings, and key definitions) in a *DITA map*.

Insert Reference Dialog Box

The **Insert Reference** dialog box allows you to insert and configure references in *DITA maps*. There are numerous types of references that can be inserted into maps. They include references to topics, other maps, glossary terms, and keys. You can also use this dialog box to configure the attributes of a reference, add profiling or metadata, and define keys.

To open the **Insert Reference** dialog box, use one of the following methods:

- Select **Reference**, **Reference to the currently edited file**, or any of the other specific reference actions that are available from the **Append Child**, **Insert Before**, and **Insert After** submenus when invoking the contextual menu in the ***DITA Maps Manager***.
  - To insert the reference as a child of the current node, select the reference from the **Append Child** submenu.
  - To insert the reference as a sibling of the current node, below the current node in the map, select the reference from the **Insert After** submenu.
  - To insert the reference as a sibling of the current node, above the current node in the map, select the reference from the **Insert Before** submenu.

  Note: The content of these submenus depends on the node that is selected in the *DITA map* tree when the contextual menu is invoked. For example, if the selected node is a topic reference (`topicref`), its possible child nodes include the following elements: `anchorref`, `chapter`, `keydef`, `mapref`, `topicgroup`, `topichead`, `topicref`, `topicset`, and `topicsetref`.
- Click the **Insert Reference** button on the **DITA Maps Manager** extended toolbar. This action will insert the reference as a sibling of the current node (below the current node in the map).
- Select **Insert Reference** from the **DITA Maps** menu. This action will insert the reference as a sibling of the current node (below the current node in the map).

For the **Reference** or **Reference to the currently edited file** actions, a **Reference type** drop-down list is displayed at the top of the **Insert Reference** dialog box and you can select the type of reference you want to insert. Depending on the place where the reference will be inserted, Oxygen XML Editor will propose only valid reference types . When you change the reference type, the fields in the various tabs of the dialog box are reconfigured depending upon the availability of the associated attributes. For the other reference actions in the **Append Child**, **Insert Before**, and **Insert After** submenus, the reference type is automatically chosen based upon the invoked action and you cannot change it.

The main section of the dialog box includes the following tabs: **Target**, **Keys**, **Attributes**, **Metadata**, and **Profiling**.

Target Tab

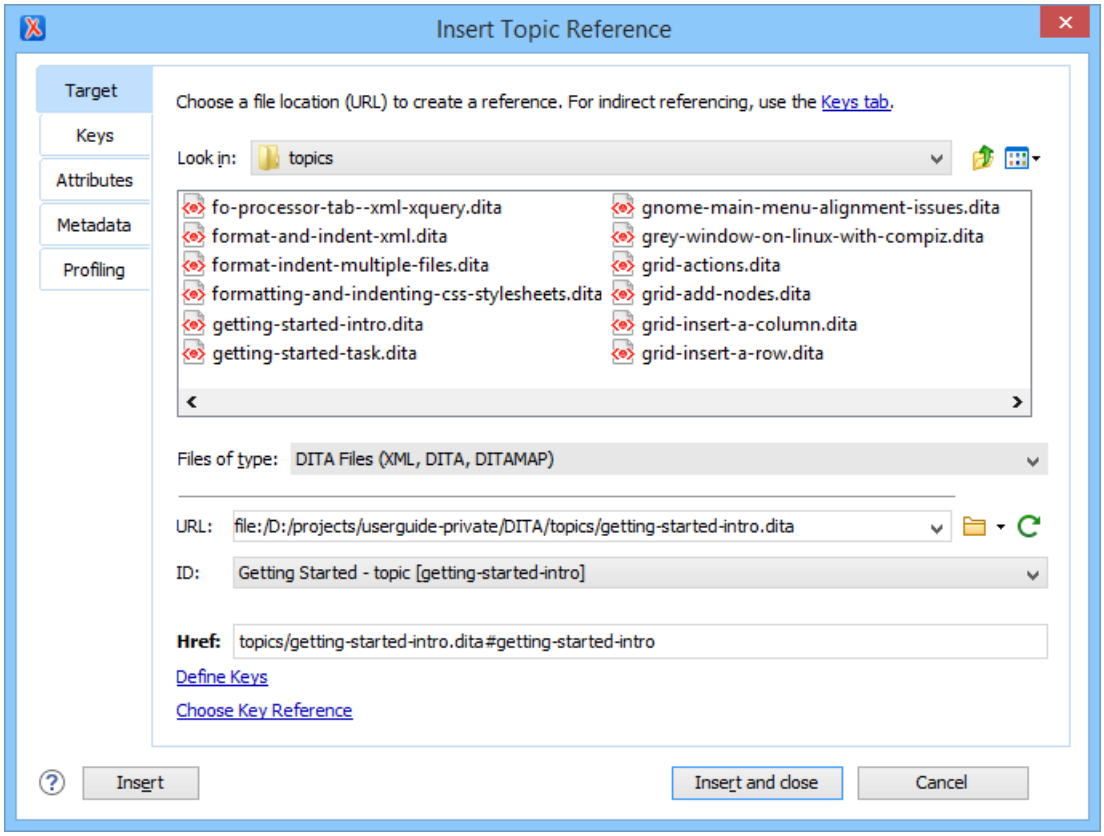

Figure 841: Insert Reference Dialog Box - Target Tab

The **Target** tab of the **Insert Reference** dialog box allows you to specify information about the target reference. It includes the following sections and fields:

Choose a file location section

You can browse for and select the source target file by using the **Look in** drop-down list, browsing tools, or file window in this section. You can use the **Files of type** drop-down menu to narrow the list of possible file types that will be displayed.

URL

Displays the path to the target and allows you to select or change it by using the combo box or browsing tools.

ID

The drop-down list displays all of the target elements that are available for the selected target URL.

Href

The selected target automatically modifies this value to point to the corresponding `href` attribute of the target element.

Note: If the **Reference type** is a **Navigation Reference**, the **Href** field is changed to **Mapref**, since a `navref` element requires a `mapref` attribute instead.

Keys Tab

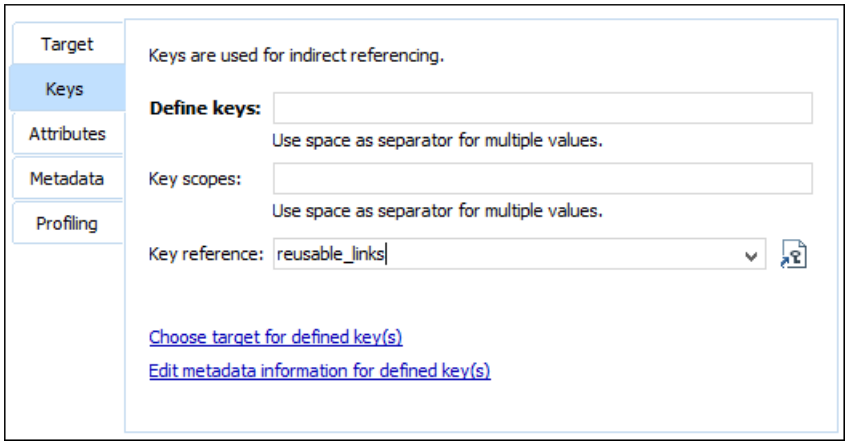

Figure 842: Insert Reference Dialog Box - Keys Tab

The **Keys** tab allows you to use and *define keys* for indirect referencing. For more information, see *Working with Keys* on page 1856. This tab includes the following:

Define keys

Use this text field to define the `keys` attribute for the target.

Key scopes [This option is only available if the *Built-in DITA-OT 2.x (with DITA 1.3 support)* option is selected in the DITA preferences page]

Use this text field to define or edit the value of a *keyscope attribute*. *Key scopes* allow you to specify different sets of key definitions for different map branches.

Key reference

Instead of using the **Target** tab to select a file that contains the target reference, you can reference a key definition by using this text field. Use the **Choose key reference** button to access the list of keys that are already defined in the current *root map*.

Attributes Tab

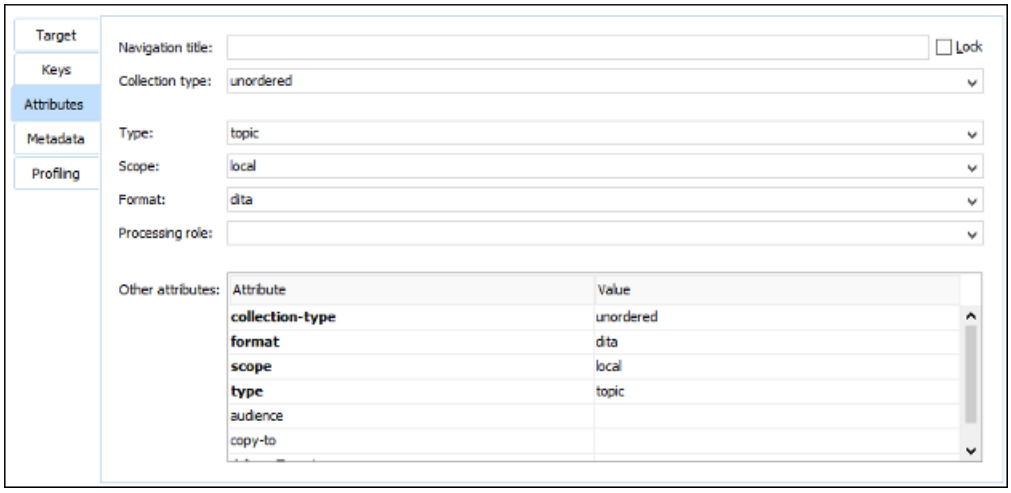

Figure 843: Insert Reference Dialog Box - Attributes Tab

The **Attributes** tab of the **Insert Reference** dialog box allows you to insert and edit attribute values for the target reference. This tab includes the following sections and actions:

Navigation title

This text field allows you to specify a custom navigation title for the target reference. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Navigation title** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*. You can enforce the use of the specified title by selecting the **Lock** checkbox.

Tip: You can also select the ***Prefer navigation title for topicref rendering*** *option in the* ***DITA*** *preferences page* to always enforce the use of the `navtitle` value rather than selecting this **Lock** option on individual topics.

Collection type

This drop-down list allows you to select the `collection-type` attribute to create hierarchical linking between topics in a *DITA map* (for example, `unordered`, `sequence`, `choice`, `family`, `-dita-use-conref-target`).

Type

Allows you to select a `type` attribute (such as `topic`, `task`, `concept`, etc.) for the target element. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Type** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*.

Scope

This property corresponds to the `scope` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Scope** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*.

Format

This property corresponds to the `format` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Format** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*.

Processing Role

This drop-down list allows you to set the `processing-role` attribute to one of the allowed values for DITA reference elements (for example, `resource-only`, `normal`, `-dita-use-conref-target`).

Other attributes table

This table contains the attributes that are available for the selected reference. You can use this table to insert or edit the values of any of the listed attributes. Clicking a cell in the **Value** column allows you to use the combo box to enter, edit, or select attribute values.

Metadata Tab

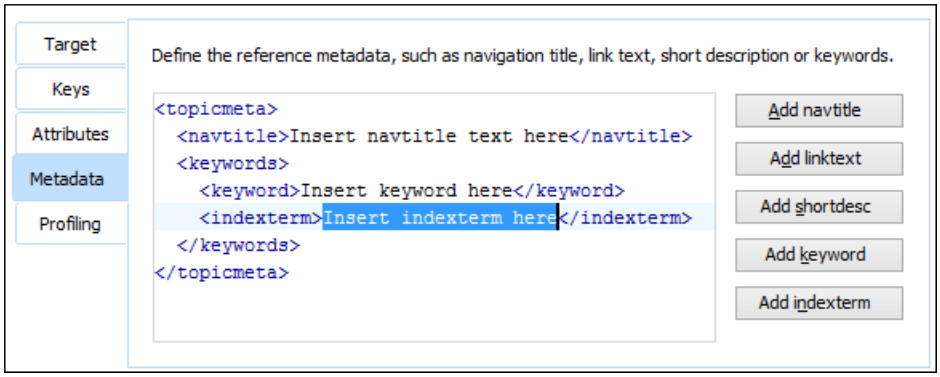

Figure 844: Insert Reference Dialog Box - Metadata Tab

The **Metadata** tab allows you to add metadata elements to the target reference. Use the buttons on the right side of the tab to insert specific metadata elements (you can add the following metadata elements: `navtitle`, `linktext`, `shortdesc`, `keyword`, `indexterm`). The metadata elements are inserted inside a `topicmeta` element. The editing window allows you to easily insert and modify the content of the metadata that will be inserted.

Profiling Tab

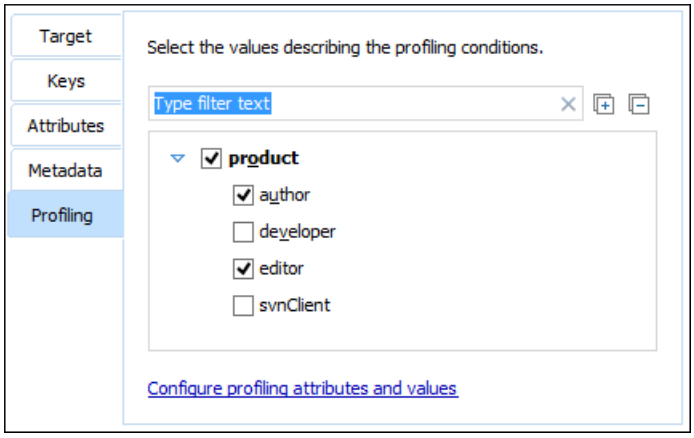

Figure 845: Insert Reference Dialog Box - Profiling Tab

The **Profiling** tab allows you to select or change profiling attributes for the selected reference. This tab displays profiling attributes and their values as determined by the following:

- If your *root map* references a DITA *subject scheme map* that defines values for the profiling attributes, those values are used.
- If your project defines *project-level* configuration values for the *profiling attributes*, those values are used.
- If Oxygen XML Editor defines *global-level* configuration values for the *profiling attributes*, they are used.
- Otherwise, a basic default set of profiling attributes and values are used.

When you modify a selection of values in this tab, the change will also automatically be reflected in the **Attributes** tab. For more information, see *DITA Profiling / Conditional Text* on page 1906.

Finalizing Your Insert Reference Configuration

Once you click **Insert** or **Insert and close**, the configured reference is added in the map.

Tip: You can easily insert multiple references by keeping the **Insert Reference** dialog box opened, using the **Insert** button.

Related Information:

DITA Profiling / Conditional Text on page 1906

Working with Keys on page 1856

Inserting Topic Headings

The `topichead` element provides a title-only entry in a navigation map, as an alternative to the fully-linked title provided by the `topicref` element.

You can insert a topic heading by doing the following:

- Select **Topic Head** from the **Append Child**, **Insert Before**, or **Insert After** submenus when invoking the contextual menu in the ***DITA Maps Manager*** *view*.
- *Open the DITA map in the XML editor* and select the **Insert Topic Heading** action from the main toolbar (or from the **Insert** submenu of the contextual menu).

Those actions open the ***Insert Topic Head*** *dialog box* that allows you to easily insert a `topichead` element. A **Navigation title** (`navtitle` attribute) is required but other attributes can also be specified from this dialog box (such as **Type**, **Scope**, **Format**, etc.)

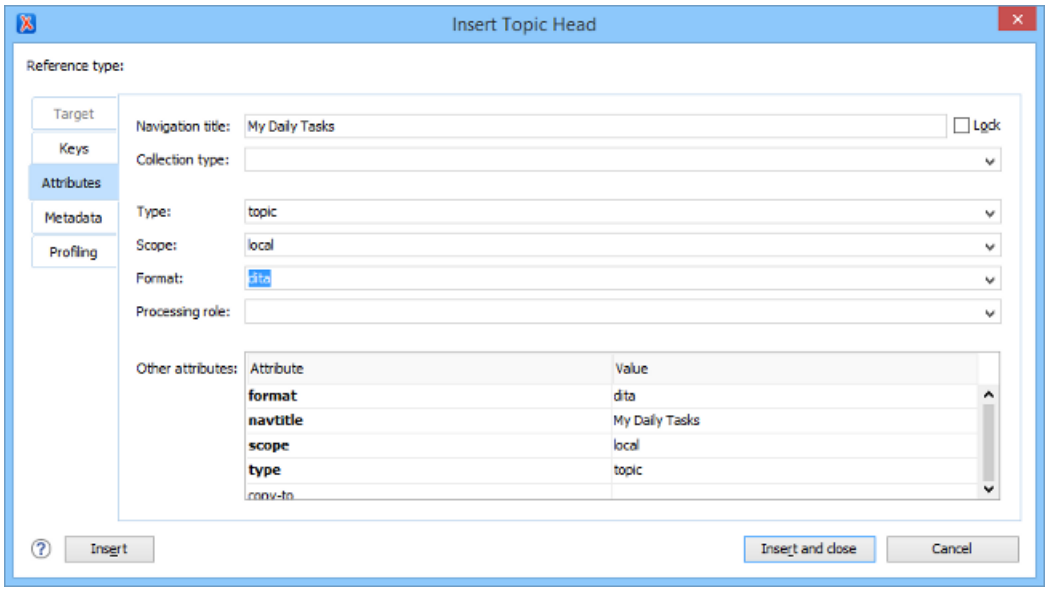

Figure 846: Insert Topic Heading Dialog Box

Related Information:

Insert Reference Dialog Box on page 1798

Inserting Topic Groups

The `topicgroup` element identifies a group of topics (such as a concepts, tasks, or references) or other resources. A `topicgroup` can contain other `topicgroup` elements, allowing you to express navigation or table-of-contents hierarchies, as well as implying relationships between the containing `topicgroup` and its children. You can set the collection-type of a container `topicgroup` to determine how its children are related to each other. Relationships end up expressed as links in the output (with each participant in a relationship having links to the other participants by default).

You can insert a topic group by doing the following:

- Select **Topic Group** from the **Append Child**, **Insert Before**, or **Insert After** submenus when invoking the contextual menu in the ***DITA Maps Manager*** *view*.
- *Open the DITA map in the XML editor* and select the **Insert Topic Group** action from the main toolbar (or from the **Insert** submenu of the contextual menu).

Those actions open the ***Insert Topic Group*** *dialog box* that allows you to easily insert a `topicgroup` element and various attributes can be specified (such as **Collection type**, **Type**, **Scope**, **Format**, etc.)

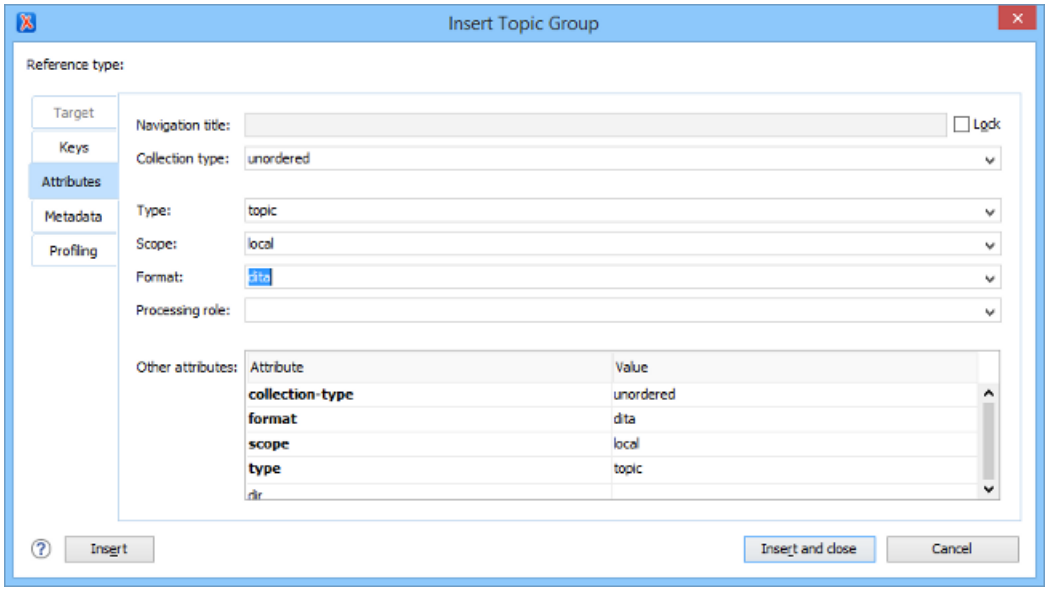

Figure 847: Insert Topic Group Dialog Box

Insert Reference Dialog Box on page 1798

Defining Keys in DITA Maps

DITA uses *keys* to insert content that may have different values in various circumstances. Keys provide the means for indirect referencing in DITA. This can make it easier to manage and to reuse content. In DITA, keys are defined in maps and can then be reused and referenced throughout the whole structure of the map.

The following example is a *DITA map* that defines various values for the `product` key:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE map PUBLIC "-//OASIS//DTD DITA Map//EN" "map.dtd">
<map>
  <!-- product name -->
  <keydef keys="product" product="basic">
    <topicmeta>
      <keywords>
        <keyword>Basic Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
  <keydef keys="product" product="pro">
    <topicmeta>
      <keywords>
        <keyword>Professional Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
  <keydef keys="product" product="enterprise">
    <topicmeta>
      <keywords>
        <keyword>Enterprise Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
</map>
```

Note: The profiling of the names is now contained in the map, where it only has to occur once to reuse throughout the whole map structure.

Key Definition with a Keyword

To insert a *key definition with a keyword* in a *DITA map*, follow these steps:

1. Open the *DITA map* in the ***DITA Maps Manager***.
2. Invoke the contextual menu and select **Key Definition** from the **Append Child**, **Insert Before**, or **Insert After** submenu (depending on where you want to insert the *key definition* in the *DITA map*). This opens an **Insert Key Definition** dialog box.
3. Go to the **Keys** tab and enter the name of the key in the **Define keys** field.
4. Go to the **Metadata** tab and click **Add keyword**. In the editing window enter the key value inside the `keyword` element.

   Note: You can profile the key by using the **Profiling** tab and other attributes can also be defined in the **Attributes** tab.
5. Once you are done configuring the *key definition*, click **Insert and close**.

Alternatively, there is a simplified method that can be used if you simply want to define a key with a value inside a *keyword*, without configuring any profiling or other attributes. To use the simplified method, follow these steps:

1. Open the *DITA map* in the ***DITA Maps Manager***.
2. Invoke the contextual menu and select **Key Definition with Keyword** from the **Append Child**, **Insert Before**, or **Insert After** submenu (depending on where you want to insert the *key definition* in the *DITA map*). This opens a simplified **Insert Key Definition** dialog box.
3. Enter the name of the key in the **Key** field and its value in the **Keyword** field.
4. Click **Insert and close** to finalize the operation.

Key Definition with a Target

To insert a *targeted key definition* (for example, to target a resource such as an image or topic) in a *DITA map*, follow these steps:

1. Open the *DITA map* in the ***DITA Maps Manager***.
2. Invoke the contextual menu and select **Key Definition** from the **Append Child**, **Insert Before**, or **Insert After** submenu (depending on where you want to insert the *key definition* in the *DITA map*). This opens an **Insert Key Definition** dialog box.
3. Go to the **Keys** tab and enter the name of the key in the **Define keys** field.
4. Go to the **Target** tab and select a target resource (such as an image or topic).

   Note: You can profile the key by using the **Profiling** tab and other attributes can also be defined in the **Attributes** tab.
5. Once you are done configuring the *targeted key definition*, click **Insert and close**.

Working with Variable Text in DITA on page 1873

Working with Keys on page 1856

Edit Properties Dialog Box

The ***DITA Maps Manager*** *view* includes a feature that allows you to view and edit the properties of a selected node. The **Edit properties** action is available on both the **DITA Maps Manager** toolbar and in the contextual menu. This action is also available in the contextual menu when you edit a *DITA map* document in **Author** mode. The action opens the **Edit Properties** dialog box and it includes several tabs with various functions and fields that are initialized with values based upon the node for which the action was invoked.

Note: If you select multiple sibling nodes and invoke the **Edit properties** action, only the **Profiling** tab will be available and your modifications in that tab will be applied to all the selected nodes. If you select multiple nodes that are not on the same hierarchical level, the other tabs will also be available and your modifications will be applied to the parent node (the child nodes will inherit the attributes of the parent node).

You can use the **Edit Properties** dialog box to modify or define attributes, metadata, profiling, or keys in *DITA maps* or topics. You can also use it to modify the title of *root maps*.

At the top of the **Edit Properties** dialog box, the **Reference type** drop-down list displays the type of the selected node and it depends on the node for which the action was invoked.

The main section of the dialog box includes the following tabs: **Target**, **Keys**, **Attributes**, **Metadata**, and **Profiling**. The availability of the tabs and their functions depend on the selected node. For example, if you invoke the action on a *root map*, only the **Attributes**, **Metadata**, and **Profiling** tabs are accessible and the **Title** property can be configured. Also, if you select multiple nodes, only the **Profiling** tab is available.

Target Tab

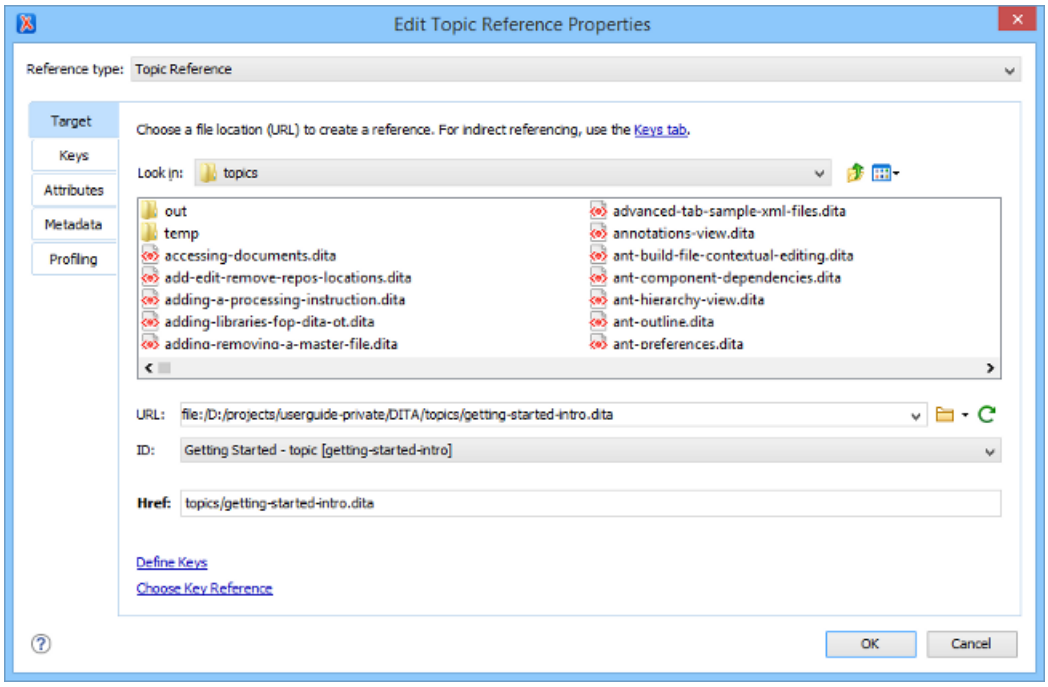

Figure 848: Edit Properties Dialog Box - Target Tab

The **Target** tab of the **Edit Properties** dialog box displays information about the target node on which the action was invoked and allows you to change the target. It includes the following sections and fields:

Choose a file location section

You can browse for and select the source target file by using the **Look in** drop-down list, browsing tools, or file window in this section. You can use the **Files of type** drop-down menu to narrow the list of possible file types that will be displayed.

URL

Displays the path to the target and allows you to select or change it by using the combo box or browsing tools.

ID

The drop-down list displays all of the target elements that are available for the selected target URL.

Href

The selected target automatically modifies this value to point to the corresponding `href` attribute of the target element.

Note: If the **Reference type** is a **Navigation Reference**, the **Href** field is changed to **Mapref**, since a `navref` element requires a `mapref` attribute instead.

Keys Tab

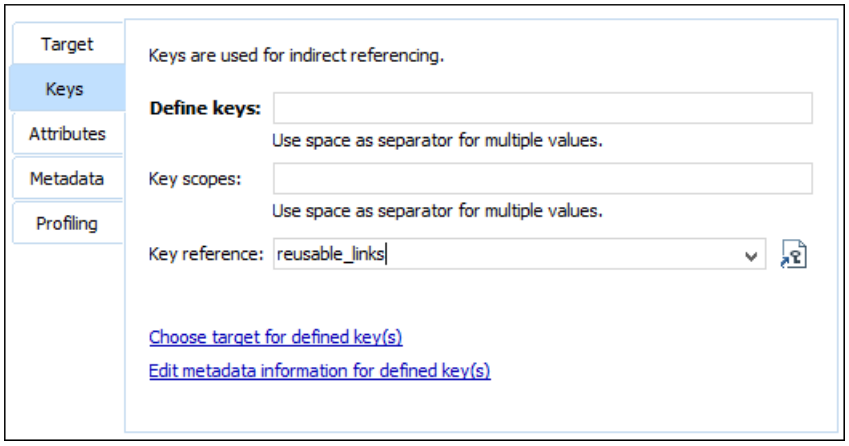

Figure 849: Edit Properties Dialog Box - Keys Tab

The **Keys** tab allows you to use and *define keys* for indirect referencing. For more information, see *Working with Keys* on page 1856. This tab includes the following:

Define keys

Use this text field to define the `keys` attribute for the target.

Key scopes [This option is only available if the *Built-in DITA-OT 2.x (with DITA 1.3 support)* option is selected in the DITA preferences page]

Use this text field to define or edit the value of a *keyscope attribute*. *Key scopes* allow you to specify different sets of key definitions for different map branches.

Key reference

Use this combo box (or the **Choose key reference** button) to select a key that is already defined in the *root map*.

Attributes Tab

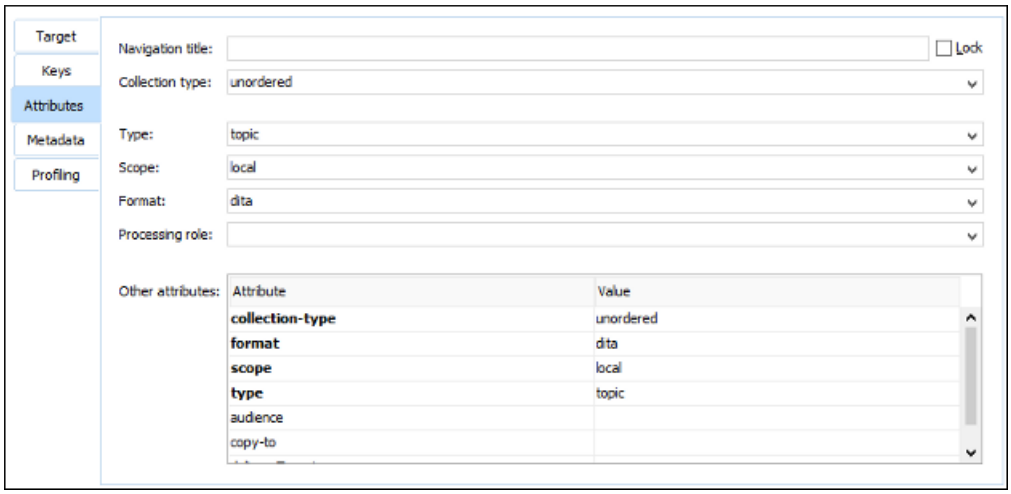

Figure 850: Edit Properties Dialog Box - Attributes Tab

The **Attributes** tab of the **Edit Properties** dialog box allows you to insert and edit attribute values for the target node for which the action was invoked.

If the target is a *root map*, the tab displays the title of the map. You can change it in the **Title** text field and assign it to an **Attribute**, **Element**, or **All**.

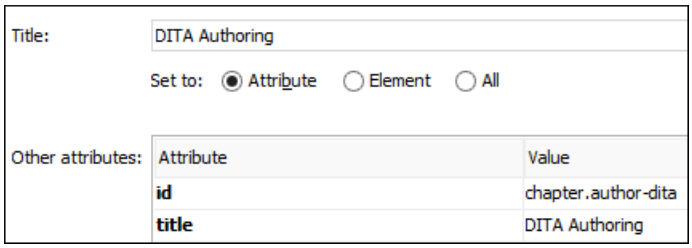

Figure 851: Attributes Tab for a Root Map

For other types of targets, the tab includes the following sections and fields that can be used to edit the attributes of the target:

Navigation title

This text field allows you to specify a custom navigation title for the target reference. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Navigation title** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*. You can enforce the use of the specified title by selecting the **Lock** checkbox.

Tip: You can also select the ***Prefer navigation title for topicref rendering*** *option in the* ***DITA*** *preferences page* to always enforce the use of the `navtitle` value rather than selecting this **Lock** option on individual topics.

Collection type

This drop-down list allows you to select the `collection-type` attribute to create hierarchical linking between topics in a *DITA map* (for example, `unordered`, `sequence`, `choice`, `family`, `-dita-use-conref-target`).

Type

Allows you to select a `type` attribute (such as `topic`, `task`, `concept`, etc.) for the target element. If you want this attribute to always be populated with a detected value (based on the specifications for the target file), select the **Type** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*.

Scope

This property corresponds to the `scope` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Scope** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*.

Format

This property corresponds to the `format` attribute of the target element. It is populated automatically, based on the selected file type, unless its value for the selected target file is the same as the default attribute value. If you want this attribute to always be populated with a detected value based on the specifications (regardless of the default value), select the **Format** checkbox for the ***Always fill values for attributes*** *option in the* ***DITA*** *preferences page*.

Processing Role

This drop-down list allows you to set the `processing-role` attribute to one of the allowed values for DITA reference elements (for example, `resource-only`, `normal`, `-dita-use-conref-target`).

Other attributes table

This table contains the attributes that are available for the selected reference. You can use this table to insert or edit the values of any of the listed attributes. Clicking a cell in the **Value** column allows you to use the combo box to enter, edit, or select attribute values.

Metadata Tab

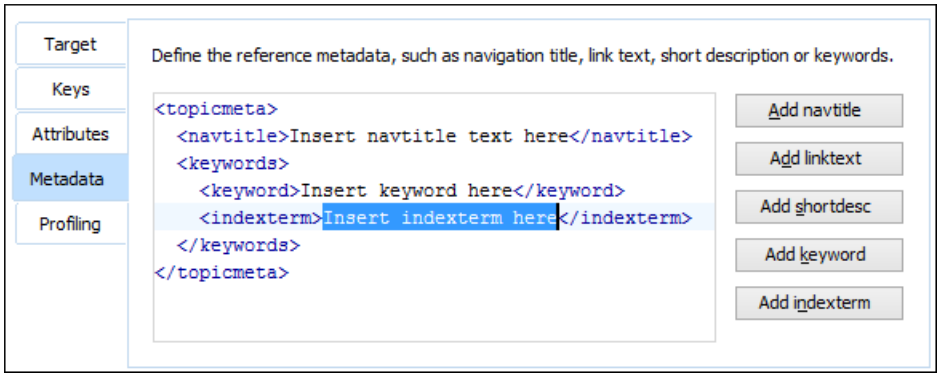

Figure 852: Edit Properties Dialog Box - Metadata Tab

The **Metadata** tab allows you to add metadata elements to the target node. Use the buttons on the right side of the tab to insert specific metadata elements (you can add the following metadata elements: `navtitle`, `linktext`, `shortdesc`, `keyword`, `indexterm`). The metadata elements are inserted inside a `topicmeta` element. The editing window allows you to easily insert and modify the content of the metadata that will be inserted.

Profiling Tab

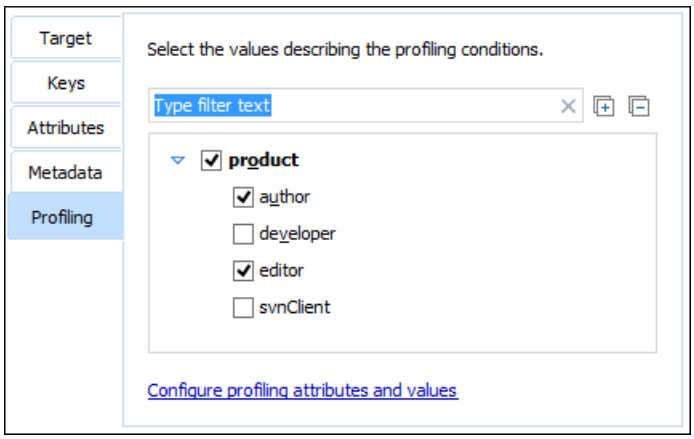

Figure 853: Edit Properties Dialog Box - Profiling Tab

The **Profiling** tab allows you to select or change profiling attributes for the selected target nodes. This tab displays profiling attributes and their values as determined by the following:

- If your *root map* references a DITA *subject scheme map* that defines values for the profiling attributes, those values are used.
- If your project defines *project-level* configuration values for the *profiling attributes*, those values are used.
- If Oxygen XML Editor defines *global-level* configuration values for the *profiling attributes*, they are used.
- Otherwise, a basic default set of profiling attributes and values are used.

If you have a large list of profiling attributes, you can use the text filter field to search for attributes or values, and you can expand or collapse attributes by using the **Expand All**/**Collapse All** buttons to the right of the text filter or the arrow button to the left of the profiling attribute name..

When you modify a selection of values in this tab, the change will also automatically be reflected in the **Attributes** tab. For more information, see *DITA Profiling / Conditional Text* on page 1906.

Note: If you invoke the **Edit properties** action on a selection of multiple nodes that have different values for the same profiling attribute, a conflict panel will be displayed in the **Profiling** tab and you can choose between the following actions for resolving it:

- **Keep** - Preserves the current attribute values.
- **Change Now** - Allows you to edit the selection of values in this **Profiling** tab and the changes will be applied to all the selected nodes.

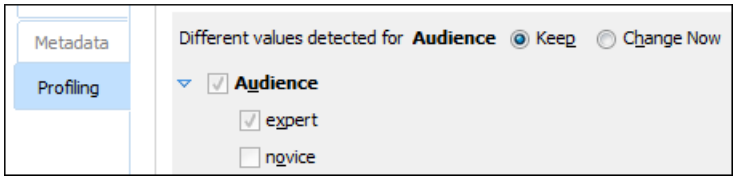

Figure 854: Profiling Conflict Panel

Finalizing Your Modifications

Once you click **OK**, all your changes are applied to the target node.

DITA Profiling / Conditional Text on page 1906

Working with Keys on page 1856

Creating a Table of Contents in DITA

In DITA, the order and hierarchy of the table of contents of a document is based directly on *the DITA map that defines the document*. In many media, the creation of a table of contents, based on the map, is automatic. For example, you do not have to do anything special to create a table of contents in WebHelp output.

In other media, you need to tell DITA where the table of contents should occur. For example, in a book you need to tell DITA where to place the table of contents in the structure of the book, and if you want to generate other common content lists, such as a list of figures or tables. You do this by *using a bookmap to define your book*, and adding the appropriate elements to the `frontmatter`.

To configure a table of contents and other book lists in a *bookmap*, follow these steps:

1. Open your *bookmap* in the ***DITA Maps Manager***.
2. If your *bookmap* is empty, right-click the *bookmap* and select **Append Child** > **Frontmatter**. If your *bookmap* already has nodes added to it, right-click the first node within *bookmap* and select **Insert Before** > **Frontmatter**. The ***Insert Reference*** *dialog box* appears.
3. Click **Insert and Close** to insert the `frontmatter` element.
4. Right-click the `frontmatter` element and create a `booklist` element using **Append child** > **Book Lists**.
5. Use the same steps to create a `toc` element and to add other `booklist` elements, such as `tablelist`.

Creating an Index in DITA

In DITA, indexes are created from `indexterm` elements. You can insert index term elements:

- In the header of a topic. In paginated media, such as a printed book or a PDF, this results in an index entry that points to the page in which the topic starts, even if it is not the page in which the indexed term occurs.
- In the `topicref` element in a map that references the topic. This applies those index terms to that topic only when used in that map, allowing you to index topics differently in various publications. In paginated media, index entries point to the page in which the topic starts.
- In the body of a topic. In paginated media, this results in an index entry that points to the page in which the `indexterm` element occurs, even if that is not the page in which the topic starts.

To add index terms to the text of a topic of the topic header, *create the elements, as you normally would, in Oxygen XML Editor*. To add index terms to a map, open the map in the editor and add the elements, as you normally would, in a topic.

In some media, indexes will be generated automatically when index entries are found in the source. For other media, such as books, you may need to tell DITA where to place the index. For instance, to add an index to a *bookmap*, you need to add an `indexlist` element to the `backmatter` of the book.

1. Open your *bookmap* in the ***DITA Maps Manager***.

2. Right-click the *bookmap* and select **Append Child** > **Backmatter**.
   The ***Insert Reference** dialog box* appears.
3. Click **Insert and Close** to insert the `backmatter` element.
4. Right-click the `backmatter` element and create a `booklists` element using **Append Child** > **Book Lists**.
5. Use the same steps to create an `indexlist` element.

CAUTION: Adding `index` entries and an `indexlist` to your project creates an instruction to the DITA publishing routines to create an index. There is no guarantee that all DITA output types or third-party customizations obey that instruction or create the index the way you want it. Modifying the output may be necessary to get the result you want.

Resolving Topic References Through an XML Catalog

There are situations where you want to resolve URIs with an *XML Catalog*:

- You customized your *DITA map* to reference topics using URIs instead of local paths.
- You have URI content references in your DITA topic files and you want to map them to local files when the map is transformed.

In such situations, you have to add the catalog to Oxygen XML Editor. The ***DITA Maps Manager** view* will solve the displayed topic refs through the added *XML catalog*, as will as *DITA map* transformations (for PDF output, XHTML output, etc.)

To add an *XML catalog* to the DITA *framework*, follow these steps:

1. Create an *XML catalog* using the guidelines described in *Working with XML Catalogs* on page 695.
2. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Document Type Association**.
3. Select the **DITA** document type and use the **Edit**, **Duplicate**, or **Extend** button to open a ***Document type** configuration dialog box*.
4. Go to the ***Catalogs** tab*.
5. Click on the  **Add** button to open a dialog box that allows you to add your created *XML Catalog* to the list.
6. After adding your catalog, click **OK**. You may need to reopen any currently edited files that use the new catalog or run *a manual **Validate** action* for the changes to take effect.

   Note: You could also add your created catalog to the list of global catalogs in the ***XML Catalog** preferences* page.

Chunking DITA Topics

By default, when a *DITA map* is published to an online format, each topic becomes a separate page in the output. In some cases, you may want to combine multiple source topics into one output page. For instance, you may want to combine several types of information into a single page, or you may have chosen to create many small DITA topics for reuse purposes but feel they are too small to be useful to a reader by themselves. This is referred to as *chunking*.

To chunk DITA topics, you set the chunking attribute on the `topicref` that contains the sub-topics in a *DITA map*. There are several values that you can set on the chunking attribute (for example, `by-topic` or `to-content`). See the *DITA documentation* for full details. To achieve the effects you want in your topics and table of contents, you may also need to set the `toc` and `collection-type` attributes on the sub-topics or container topic to suitable values. See the *DITA documentation* for details.

You can set the `collection-type` attribute on your topics using the **Edit Properties** action in the ***DITA Maps Manager***. To set the `toc` and `chunk` attributes, you must open the map file in the editor and add or edit the attributes directly (double-click the map icon in the ***DITA Maps Manager*** to open the map in the editor).

DITA Map Validation and Completeness Check

You should validate your *DITA maps* regularly to make sure that your maps and topics are valid, and all of the relationships between them are working. Changing one topic, image, or piece of metadata may create errors in references that rely on them. You may not discover these problems all at once. Validate your map to catch all of

these kinds of problems. The longer you wait between validating your maps, the more difficult it may be to detect and correct any errors you find.

Validating a DITA Map

To validate a DITA, follow these steps:

1. In the ***DITA Maps Manager*** *view*, make sure that the tab that holds your *root map* is selected and that the **Root map** selection is set either to the name of your *root map* or to `<current map>`.
2. It is a good practice to refresh your *DITA map* before running the validation process. To do so, select the *DITA map* in the **DITA Maps Manager** view and click **Reload (F5)**.
3. Click the **Validate and Check for Completeness** button on the **DITA Maps Manager** toolbar to open the ***DITA Map Completeness Check*** *dialog box*.
4. If you are using profiling, check the **Use DITAVAL filters** box and select the appropriate option.
5. Select any other options you want to check.
6. Click **Check** to run the validation process.

Validation Process

The validation process of a *DITA map* includes the following:

- Verifies that the file paths of the topic references are valid. For example, if an `href` attribute points to an invalid file path, it is reported as an error in the message panel at the bottom of the editor.
- Validates each referenced topic and map. Each topic file is opened and validated against the appropriate DITA DTD. If another *DITA map* is referenced in the main one, the referenced *DITA map* is verified recursively, applying the same algorithm as for the main map.
- If errors or warnings are found, they are displayed in a separate message pane at the bottom of the editor and clicking them takes you to the location of the error or warning in the file where it was found.

DITA Map Completeness Check Dialog Box

The **DITA Map Completeness Check** dialog box allows you to configure the *DITA map* validation.

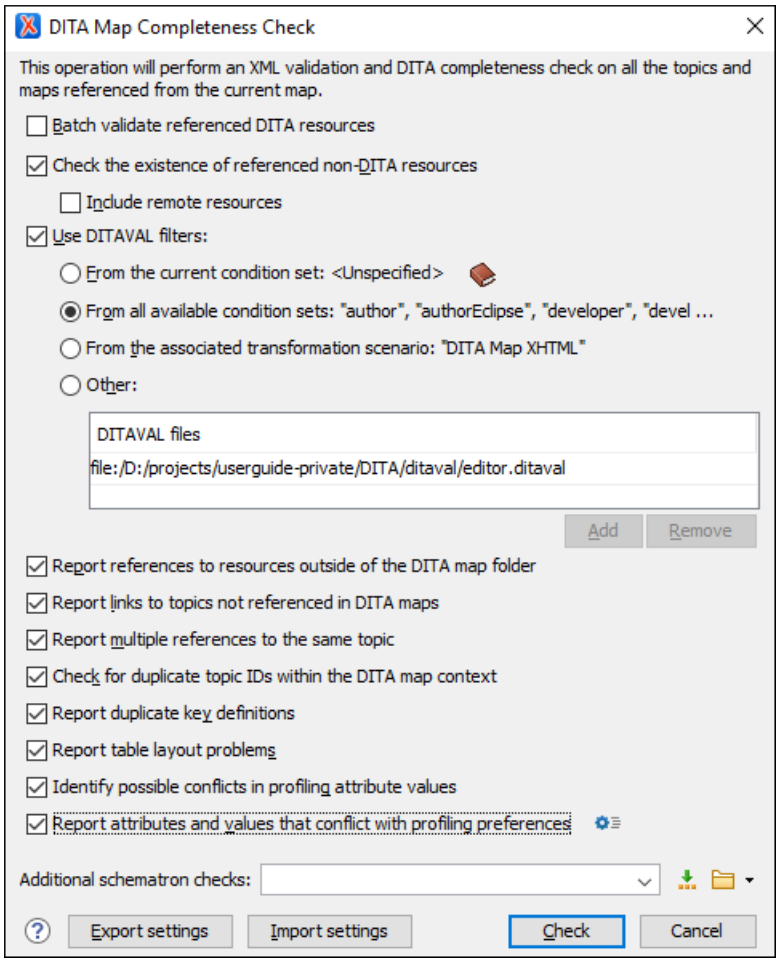

Figure 855: DITA Map Completeness Check Dialog Box

You can configure the validation process with the following options that are available in the **DITA Map Completeness Check** dialog box:

Batch validate referenced DITA resources

This option specifies the level of validation that applies to referenced DITA files:

- If the checkbox is left unchecked (default setting), the DITA files will be validated using the rules defined in the DTD or XML Schema declared in the document.
- If the checkbox is selected, the DITA files will be validated using rules defined in their associated *validation scenario*.

Check the existence of non-DITA references resources

Extends the validation of referenced resources to non-DITA files.

Include remote resources

Select this option if you want to check that remote referenced binary resources (such as images, movie clips, ZIP archives) exist at the specified location.

Use DITAVAL filters

The content of the map is filtered by applying a *profiling condition set* before validation. You can choose between the following options:

- **From the current condition set** - The map is filtered using the condition set currently applied in the ***DITA Maps Manager** view*. Clicking the **Details** icon opens a topic in the Oxygen XML Editor User Guide that explains how to create a profiling condition set.
- **From all available condition sets** - For each available condition set, the map content is filtered using that set before validation.

- **From the associated transformation scenario** - The filtering condition set is specified explicitly as a DITAVAL file in the current transformation scenario associated with the *DITA map*.
- **Other DITAVAL files** - For each DITAVAL file from this list, the map content is filtered using the DITAVAL file before validation. Use the **Add** or **Remove** buttons to configure the list. The **Add** button opens a dialog box that allows you to select a local or remote path to a DITAVAL file. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list.

Report references to resources outside of the DITA map folder

If selected, it will report any references to DITA resources that are located outside the *main DITA map* folder.

Report links to topics not referenced in DITA maps

Checks that all the topics referenced by other topics are also linked in the *DITA map*.

Report multiple references to the same topic

If selected, it will report warnings when a topic is referenced multiple times in the *DITA map*, unless a unique `copy-to` attribute is used on the `topicref` element for any topic that is referenced multiple times.

For example, it will **not** report a warning if there is a topic referenced twice, but the second `topicref` has a `copy-to` attribute set:

```
<topicref href="topic.dita"/>
.....
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

On the other hand, it **will** report a warning if there is a topic referenced twice and none of the reference-type elements has a `copy-to` attribute set or both of them have the `copy-to` attribute set to the same value:

```
<topicref href="topic.dita" copy-to="topic2.dita"/>
......
 <topicref href="topic.dita" copy-to="topic2.dita"/>
```

Check for duplicate topic IDs within the DITA map context

Checks for multiple topics with the same ID in the context of the entire map.

Report duplicate key definitions

Checks the *DITA map* for multiple key references with the same key defined for them. This is helpful because if you have two different resources with the same value for the `keys` attribute, all references will point to the first one encountered and the other will be ignored.

Note: This option takes *key scopes* into account. For example, if you have something like this:

```
<topicref href="t2.dita" keys="k2"/>
    <topicgroup keyscope="ks">
        <topicref href="t2.dita" keys="k2"/>
    </topicgroup>
```

it will not report the "k2" key as a duplicate because it is defined in a *key scope* on the second occurrence.

Report table layout problems

Looks for table layout problems. The types of errors that may be reported include:

- If a row has fewer cells than the number of columns detected.
- For a *CALS* table, if a cell has a vertical span greater than the available rows count.
- For a *CALS* table, if the number of `colspecs` is different than the number of columns detected from the table `cols` attribute.
- For a *CALS* table, if the number of columns detected from the table `cols` attribute is different than the number of columns detected in the table structure.
- For a *CALS* table, if the value of the `cols`, `rowsep`, or `colsep` attributes are not numeric.
- For a *CALS* table, if the `namest`, `nameend`, or `colname` attributes point to an incorrect column name.

Identify possible conflicts in profile attribute values

When the profiling attributes of a topic contain values that are not found in parent topic profiling attributes, the content of the topic is overshadowed when generating profiled output. This option reports these possible conflicts.

Report attributes and values that conflict with profiling preferences

Looks for profiling attributes and values that are not defined in the ***Profiling / Conditional Text*** *preferences page* (you can click the **Profiling Preferences** button to open this preferences page). It also checks if profiling attributes defined as *single-value* have multiple values set in the searched topics.

Additional schematron checks

Allows you to select a Schematron file that Oxygen XML Editor will use for the validation of DITA resources. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list.

Export settings

Allows you to export the settings assigned in this dialog box to an XML file that you can share with other users or use on other systems.

Import settings

Allows you to import settings for this dialog box from an XML file that was created by the **Export settings** action.

Check

Use the **Check** button to begin the validation process. The options that you choose in this dialog box are preserved between sessions.

Related Information:

DITA Maps Manager on page 1784

DITA Map Validation and Completeness Check from the Command-Line Interface

Important: This command-line script requires a special **Oxygen XML Scripting License** and does not work with a normal Oxygen XML Editor license. For more information and to obtain an **Oxygen XML Scripting License** license, see the *Oxygen XML Scripting Web Page*.

You can execute a ***Validate and Check for Completeness*** *operation* with a script ran from the command-line interface. The operation can be executed by running the following script:

- **Windows:**

```
validateCheckDITA.bat -i mainDitamapPath -s settingsFile -r reportFile
```

- **Linux:**

```
sh validateCheckDITA.sh -i mainDitamapPath -s settingsFile -r reportFile
```

- **Mac OS X:**

```
sh validateCheckDITA.sh -i mainDitamapPath -s settingsFile -r reportFile
```

The script is located in the Oxygen XML Editor installation folder and can be integrated in an external batch process launched from the command-line interface. The script accepts a variety command line arguments that allow you to configure the validation.

The accepted arguments are as follows:

mainDitamapPath

The path to the main *DITA map* file to validate. This is a required parameter.

settingsFile

The options file for the validate and completeness check. This file can be obtained from the ***DITA Map Completeness Check*** *dialog box* by using the **Export Settings** action. If this parameter is missing, the default options for the validation will be used.

reportFile

The file where the validation report will be saved. If this parameter is missing, the report will be displayed in the console.

Note: When using this script, some of the options that appear in the ***DITA Map Completeness Check*** *dialog box* are ignored. The ignored options include:

- ***Batch validate referenced DITA resources***
- ***Use DITAVAL filters: From the current condition set***
- ***Use DITAVAL filters: From all available condition sets***
- ***Use DITAVAL filters: From the associated transformation scenario***
- ***Report attributes and values that conflict with profiling preferences***

Tip: You can use DITAVAL filter files with the script by specifying one or more `ditaval` files in the ***Use DITAVAL filters: Other DITAVAL files*** *option* in the **DITA Map Completeness Check** dialog box.

Result: The validation result is displayed in the command line interface. This includes whether or not the validation was successful, the number of issues, and the path to the report file (if the reportFile parameter was used), or the actual content of the validation result if the reportFile parameter was not used.

Restriction: When using this script, the Saxon 9 XSLT processor used to apply *custom Schematron checks* is not licensed and therefore the Schematron cannot call external Java extensions.

DITA Map Author Mode Actions

A variety of actions are available in the *DITA map framework* that can be added to the **DITA** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

DITA Map Toolbar and Menu Actions

When a *DITA map* is opened in **Author** mode, the following default actions are available on the **DITA Map Author Custom Actions** toolbar (by default, they are also available in the **DITA** menu and in various submenus of the contextual menu):

Insert New Topic

Opens a ***New*** *DITA topic dialog box* that allows you to create a new topic and inserts a reference to it at the cursor position.

Insert Topic Reference

Opens the ***Insert Reference*** *dialog box* that allows you to insert and configure a reference to a topic at the cursor position.

Reuse Content

Opens the ***Reuse Content*** *dialog box* that allows you to insert and configure a content reference (`conref`), or a content key reference (`conkeyref`) at the cursor position.

Insert Topic Heading

Opens the ***Insert Reference*** *dialog box* that allows you to insert a topic heading at the cursor position.

Insert Topic Group

Opens the ***Insert Reference*** *dialog box* that allows you to insert a topic group at the cursor position.

Insert Relationship Table

Opens a dialog box that allows you to configure the relationship table to be inserted. The dialog box allows you to configure the number of rows and columns of the relationship table, if the header will be generated and if the title will be added.

Relationship Table Properties

Allows you to change the properties of rows in relationship tables.

Insert Relationship Row

Inserts a new table row with empty cells. The action is available when the cursor position is inside a table.

Insert Relationship Column

Inserts a new table column with empty cells after the current column. The action is available when the cursor position is inside a table.

Delete Relationship Column

Deletes the table column where the cursor is located.

Delete Relationship Row

Deletes the table row where the cursor is located.

Move Up

Moves the selected node up one position on its same level.

Move Down

Moves the selected node down one position on its same level.

Promote(Alt + LeftArrow)

Moves the selected node up one level to the level of its parent node.

Demote(Alt + RightArrow)

Moves the selected node down one level to the level of its child nodes.

DITA Menu Actions

In addition, the following default actions are available in the **DITA** menu when editing a *DITA map* in **Author** mode:

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is *cut* and *pasted*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

DITA Map Contextual Menu Actions

In addition to many of the ***DITA Map*** *toolbar actions* and the *general* ***Author*** *mode contextual menu actions*, the following *DITA map framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see *Edit Properties Dialog Box* on page 1805.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Search References

Finds the references to the `href` or `keys` attribute value of the topic/map reference element at the current cursor position, in all the topics from the current *DITA map* (opened in the ***DITA Maps Manager*** *view*). The current topic/map reference element must have an `href` or `keys` attribute defined to complete the search.

Show Key Definition

Available for elements that have a `conkeyref` or `keyref` attribute set (or elements with an ancestor element that has a `conkeyref` or `keyref` attribute). It computes the key name and opens the *DITA map* that contains the definition of the key with the element that defines that key selected.

DITA Map Drag/Drop Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a *DITA map* document that is edited in **Author** mode creates a link to the dragged file (a `topicref` element, `chapter`, `part`, etc.) at the drop location.

Open Topic from DITA Map in Author Mode

When a *DITA map* is opened in **Author** mode, you can click the icon to the left of a topic to open that particular topic in the editor.

Working with DITA Topics

DITA is a structured writing format. Structure can have several meanings, all of which are relevant to DITA. This section includes information about working with DITA topics and the structure.

Information Types

The structure of a piece of content refers to how the words and images are selected and organized to convey information. One approach to structured writing is to divide content into discrete blocks that contain various types of information, and then to combine those blocks to form publications. DITA is based on this approach, and encourages the author to write in discrete blocks called topics. DITA provides three base topic types (concept, task, and reference), a number of extended topic types, and the capability to create new topic types through specialization.

Text Structure

Every piece of text is made up of certain text structures, such as paragraphs, lists, and tables. DITA supports text structures through XML elements such as `p`, `ol`, and `simpletable`. *The DITA markup* specifies the text structures, but not how they will be published in various types of media. The formatting of text structures is determined by the output transformations and may be customized to meet the needs of various organizations and type of media.

Semantic Structure

Semantic structure is structure that shows the meaning of things. For example:

- A `task` element specifies that a block of content contains the description of a task.
- A `codeblock` element specifies that a block of text consists of programming code.
- A `uicontrol` element specifies that a word is the name of a control in a computer GUI.
- The `platform` profiling attribute specifies that a particular piece of content applies only to certain computing platforms.

Semantic structure is important in a structured writing system because it allows both authors and readers to find content, and it allows processing scripts to process various pieces of content differently, based on their role or meaning. This can be used to do things such as filtering content related to a specific product so that you can produce documentation on many products from the same source.

There can be many forms of semantics captured in a document set. DITA captures some of these in topics and some of them in maps. If you are using a CMS, it may capture additional semantics.

Document Semantics

Documents consist of elements that may be made up of the same basic text structures as the rest of the text, but have a special function within the structure of the document. For instance, both tables of contents and indexes are lists, but they play a special role in the document. Chapters and sections are just sequences of paragraphs and other text structures, yet they are meaningful in the structure of the document. In some cases, such as indexes and tables of contents, these structures can be generated from semantic information embedded in the source. For instance, a table of contents can be built by reading the titles of chapters and sections. DITA provides elements to describe common document semantics.

Subject Matter Semantics

In some cases, the semantics of the content relate directly to the subject matter that the content describes. For instance, DITA supports tags that allow you to mark a piece of text as the name of a window in a software application (`wintitle`), or to mark a piece of text as applying only to a particular product.

Audience Semantics

In some cases, the semantics of the content relate to the audience that it is addressed to. For instance, a topic might be addressed to a particular role, or to a person with a particular level of experience. DITA provides an `audience` element to capture audience metadata.

Creating Topic Structures

Oxygen XML Editor provides a number of tools to help you create topic structures:

- *Content Completion Assistant* - Shows you which elements can be created at the current position.
- ***Model*** *view* - Shows you the complete structure supported by the current element.
- ***Outline*** *view* - Shows you the current structure of your document.
- **DITA** toolbar - Helps you to easily insert many common structures.

Your First DITA Topic on page 9
DITA Topics Document Type (Framework) on page 1003

Creating a New DITA Topic

The basic building block for DITA information is the DITA topic. DITA provides a variety of specialized topic types, the most common of which are:

- *Topic* - The base topic type from which all other topic types are specialized. Typically, it is used when a more specialized topic type is inappropriate.
- *Task* - For procedural information such as how to use a dialog box.
- *Concept* - For general, conceptual information such as a description of a product or feature.
- *Reference* - For reference information.

Oxygen XML Editor also supports numerous other specialized topic types that you will find templates for in the various folder in the ***New*** *DITA file dialog box*. They include DITA 1.3 specializations, Lightweight DITA templates, MathML composites, Markdown documents, and other DITA specialized topic and *DITA map* types such as *Glossentry*, *Troubleshooting*, *Bookmap*, and *Subject Scheme Map*.

To create a new DITA topic and add a reference to it in your *DITA map*, follow these steps:

1. In the ***DITA Maps Manager***, right-click the node in the current map where you want to add the new topic.
2. Select one of the following actions:
   - **Append Child** > **New** - Select this action to insert the new topic as a child of the selected node. This action opens a ***New*** *file dialog box* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.

- **Insert Before** > **New** - Select this action to insert the new topic as a sibling to the current node, before it. This action opens a ***New*** *file dialog box* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
- **Insert After** > **New** - Select this action to insert the new topic as a sibling to the current node, after it. This action opens a ***New*** *file dialog box* that allows you to select the type of document and assists you with naming it. After you have configured your new topic, click **Create**.
- **Duplicate** - Select this action to create a copy of the selected topic and insert it as a sibling. This action opens a dialog box that allows you to choose the file name and location for the newly created copy of the topic. After you have selected the name and path for your new topic, click **OK**.

Step Result: The new topic is now referenced (as a `topicref`) in the *DITA map* at the location where you inserted it and the new topic is opened in the editor.

3. Save the *DITA map*.

New DITA File Dialog Box

The **New** DITA file dialog box allows you to create a new DITA topic using various types of DITA file templates and provides some options that help you to configure the new topic.

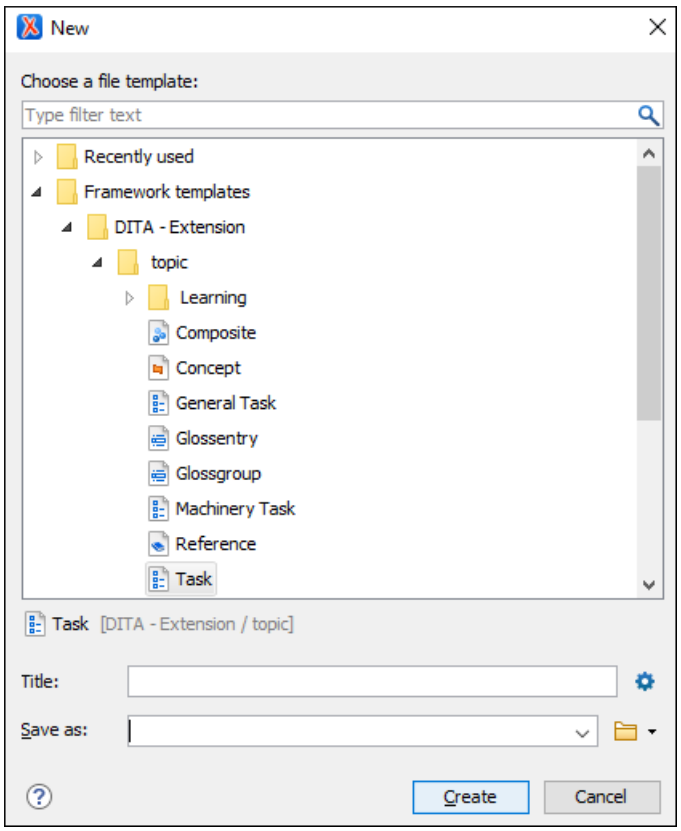

Figure 856: New DITA File Dialog Box

Note: The templates that appear in this dialog box include all templates that have an associated `.properties` file and the `type` property is set to **dita**, as well as templates that do not have an associated properties file or the `type` property is not defined. It will also include custom templates that you create using the procedures presented in *Creating New Document Templates* on page 442.

The **New** DITA file dialog box includes the following features and options:

Choose a file template

Use the template preview pane to select the appropriate type of DITA file you want to create. Once you select a template, the other options will appear below the preview pane.

Tip: You can use the text filter field at the top of the dialog box to search for a specific template.

Title

Depending on the selected file template, the value of the **Title** field is set in:

- the `title` element of a DITA topic file. The `title` element needs to be the first child of the root element.
- the `glossterm` element of a *Glossentry* file.

New Topics Preferences

Pressing this button opens the *DITA New Topics preference page*

Save as

Use this option to specify a file name and path for the new file. You can specify the path by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down menu.

Create

When you click this button, a reference (`topicref`) to the new topic is added to the current *DITA map* and the new topic is opened in the editor.

Related Information:

Your First DITA Topic on page 9
Adding Topics to a DITA Map on page 1795
Working with Markdown Documents in DITA on page 928
Fast Create Multiple DITA Topics on page 1822

Fast Create Multiple DITA Topics

The ***DITA Maps Manager*** includes a feature that allows you to quickly create multiple skeleton topics at once and you can specify their hierarchical structure within the *DITA map*. A common use-case for using this feature is when you need to insert a new chapter or section that will include multiple topics and you have the structure and titles planned out in advance.

Note: The **Fast Create Topics** feature works for the following types of local and remote resource protocols: *file*, *http*, *https*, *ftp*, *ftps*.

To access this feature, right-click a node in the **DITA Maps Manager** where you want the new topics to be inserted and select **Fast Create Topics**. This opens the **Fast Create Topics** dialog box where you can configure the structure for the new topics.

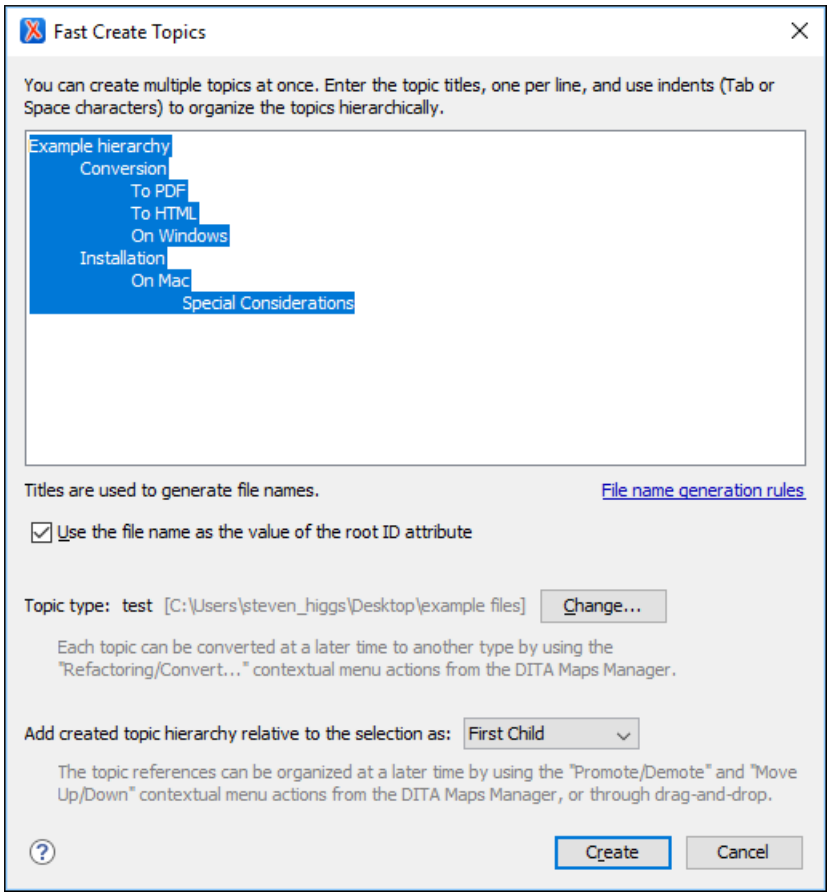

Figure 857: Fast Create Topics Dialog Box

The **Fast Create Topics** dialog box includes the following features and options:

Hierarchy Text Pane

Use this text area to enter the titles for your new topics, one per line, and specify the hierarchy by using indents (**Tab** or **Space**). Topic references will be created in the *DITA map* according to the hierarchy you enter in this section.

File name generation rules

The titles that you enter in the text pane will not only be used for the topic titles but also to generate their file names and you can click the ***File name generation rules*** *link to configure the rules* for how those file names will be generated.

Tip: If you have added a *file name prefix or suffix to the properties file* for DITA document templates, the generated file name will include that prefix or suffix.

Use the file name as the value of the root ID attribute

Select this option to use the file name (without the file extension) as the value of the root `id` attribute for the new topics.

Topic type

All of the topics that will be created will have the same DITA topic type, which is detected from the most recently created topic. You can click the **Change** button to select a different type from a list of possible DITA templates.

Tip: You can convert any of these new files to a different DITA topic type at a later time by using another *feature that allows you to easily convert DITA documents to other types*.

Add created topic hierarchy relative to the selection as

By default, the hierarchy of topics will be added to the *DITA map* as the **First Child** of the node where the action was invoked. You can change this to **Last Child**, **Preceding Sibling**, or **Following Sibling** if the selected node allows topics to be inserted as such.

Create

When you click **Create**, the specified hierarchy is added as topic references in the *DITA map*. The new documents are created as bare skeleton topics with only the topic title and possibly the root ID populated.

Tip: You can easily *change the order of the topics in the DITA map* at a later time,

Related Information:

Adding Topics to a DITA Map on page 1795
Converting DITA Topics to Another Type on page 1826

Editing DITA Topics

Oxygen XML Editor provides a number of features to help you edit DITA topics. A DITA topic is an XML document, thus all the editing features that Oxygen XML Editor provides for editing XML documents also apply to DITA topics. Oxygen XML Editor also provides extensive additional support specifically for DITA.

Opening a DITA Topic

There are several ways to open a DITA topic in the XML editor. Use any of the following methods to open a topic:

- Double-click the topic in the ***DITA Maps Manager*** (or right-click the topic and select **Open**).
- Double-click the file in the ***Project*** *view* (or right-click the file and select **Open**).
- If you have a *DITA map* opened in the XML editor, you can click the  icon to the left of the topic.
- Drag a DITA file from your system browser and drop it in the XML editor.

Visual Editing in Author Mode

DITA is an *XML format*, although you do not have to write raw XML to create and edit DITA topics. Oxygen XML Editor provides a graphical view of your topics in ***Author*** *mode*. Your topics will likely open in **Author** mode by default, so this is the first view you will see when you open or edit a DITA topic. If your topic does not open in **Author** mode, just click **Author** at the bottom left of the editor window to switch to this mode.

Author mode presents a graphical view of the document you are editing, similar to the view you would see in a word processor. However, there are some differences, including:

- **Author** mode is not a **WYSIWYG** view. It does not show you exactly what your content will look like when printed or displayed on-screen. The appearance of your output is determined by the DITA publishing process, and your organization may have modified that process to change how the output is displayed. Oxygen XML Editor has no way of determining what your final output will look like or where line breaks or page breaks will fall. Treat **Author** mode as a friendly visual editing environment, not a faithful preview of your output.
- Your document is still an XML document. **Author** mode creates a visual representation of your document by applying a CSS stylesheet to the XML. You can see the XML at any time by switching to ***Text*** *mode*. You, or someone in your organization, can change how the **Author** view looks by changing the CSS stylesheet or providing an alternate stylesheet.
- Your aim in editing a DITA document is not to make it look right, but to create a complete and correct DITA XML document. **Author** mode keeps you informed of the correctness of your content by highlighting XML errors in the text and showing you the current status in a box at the top right of the editor window. Green means that your document is valid, yellow means valid with warnings, and red means invalid. Warnings and errors are displayed when you place the cursor on the error location.
- Your XML elements may have attributes set on them. Conventionally, attributes are used to contain metadata that is not displayed to the reader. By default, attributes are not displayed in the **Author** view (though there are some exceptions) and cannot be edited directly in the **Author** view (though in some cases the CSS that drives the display may use form controls to let you edit attributes directly). To edit the attributes of an element, place your cursor on the element and press **Alt+Enter** to bring up the attribute editor. Alternatively, you can use the ***Attributes*** *view* to edit attributes.

Tip: You can select **Hints** from the **Styles** drop-down menu (available on the **Author Styles** toolbar) to display tooltips throughout the DITA document that offers additional information to help you with the DITA structure. For more information, see the *Selecting and Combining Multiple CSS Styles* section.

Content Completion Assistance

Since it is a structured format, DITA only allows certain elements in certain places. The set of elements allowed differ from one DITA topic type to another (this is what makes one topic type different from another). To help you figure out which elements you can add in any given place and help you understand what they mean, Oxygen XML Editor has a number of *Content Completion Assistant* features.

- **The Enter key:** In **Author** mode, the Enter key does not create line breaks, it brings up the *Content Completion Assistant* to help you enter a new element. In XML, you do not use line breaks to separate paragraphs. You create paragraphs by creating paragraph elements (element p in DITA) and tools insert the line breaks in the output and on-screen.

  

  Figure 858: Content Completion Assistant

  The *Content Completion Assistant* not only suggests new elements you can add. If you press **Enter** at the end of a *block element* (such as a paragraph) it suggests creating a new element of the same type. If you press **Enter** in the middle of a *block element*, it suggests splitting that element into two elements.

  A useful consequence of this behavior is that you can create a new paragraph simply by hitting **Enter** twice (just as you might in a text editor).

  As you highlight an element name, a basic description of the element is displayed. Select the desired element and press **Enter** to create it.

  To wrap an element around an existing element or piece of text, simply select it and press **Enter** and use the *Content Completion Assistant* to choose the wrapper element.
- **The Model view:** You can see the entire model of the current element by opening the ***Model** view* (**Window** > **Show View** > **Model**, if the view is not already open). The **Model** view shows you what type of content the current element can contain, all the child elements it can contain, all its permitted attributes, and their types.

Tip: You can also select **Inline actions** from the **Styles** drop-down menu (available on the **Author Styles** toolbar) to display possible elements that are allowed to be inserted at various locations throughout the DITA document. For more information, see the *Selecting and Combining Multiple CSS Styles* section.

DITA Editing Actions

A variety of actions are available in the DITA *framework* to specifically assist you with editing DITA documents. These various actions are available in the contextual menu, the **DITA** menu, the **DITA (Author Custom Actions)** toolbar, or the *Content Completion Assistant*.

The **DITA** toolbar contains buttons for inserting a number of common DITA elements (elements that are found in most DITA topic types).

If the **DITA** toolbar is not displayed, right-click anywhere on the toolbar area, select **Configure Toolbars**, and select it from the displayed dialog box.

Note: The **DITA** toolbar contains a list of the most common elements and actions for DITA, such as inserting an image, creating a link, inserting a content reference, or creating a table. It does not contain a button for inserting every possible DITA element. For a complete list of elements that you can insert at the current location in your document, press **Enter** to open the *Content Completion Assistant*.

Whenever the current document in the editor is a DITA document, the **DITA** menu is displayed in the menu bar. It contains a large number of actions for inserting elements, creating content references and keys, editing DITA documents, and controlling the display. These actions are specific to DITA and supplement the general

editing commands available for all document types. Many of these actions are also conveniently available in the contextual menu. In addition to the *DITA framework-specific actions*, the contextual menu also includes various *general **Author** mode contextual menu actions*.

Your First DITA Topic on page 9
DITA Author Mode Actions on page 1004

Converting DITA Topics to Another Type

Oxygen XML Editor includes a features that allows you to convert an existing DITA document to a different topic type. For example, if you want to convert a DITA Task to a DITA Topic, or vice versa. There are several ways to access these refactoring actions and you can choose a scope for the operation and some filtering options.

DITA Conversion Refactoring Operations for *DITA*

The following conversion operations are available:

Convert to Concept

Use this operation to convert a DITA topic (of any type) to a DITA Concept topic type (for example, Topic to Concept).

Convert to General Task

Use this operation to convert a DITA topic (of any type) to a DITA General Task topic type (for example, Task to General Task). A DITA *General Task* is a less restrictive alternative to the *Strict Task* information type.

Convert to Reference

Use this operation to convert a DITA topic (of any type) to a DITA Reference topic type (for example, Topic to Reference).

Convert to Task

Use this operation to convert a DITA topic (of any type) to a DITA Task topic type (for example, Topic to Task).

Convert to Topic

Use this operation to convert a DITA topic (of any type) to a DITA Topic (for example, Task to Topic).

Convert to Troubleshooting

Use this operation to convert a DITA topic (of any type) to a DITA Troubleshooting topic type (for example, Topic to Troubleshooting).

Methods for Accessing the DITA Conversion Refactoring Operations

To access the conversion operations, use one of the following methods:

Single Document Method

With the document opened in the editor, right-click anywhere in the main editing pane (or right-click the topic reference in the ***DITA Maps Manager***), go to the **Refactoring** submenu, and choose whichever operation is appropriate for your needs.

Multiple Documents At Once Method

Select **XML Refactoring** from the **Tools** menu (or from the **Refactoring** submenu when you right-click one or more documents in the ***Project** view*or the ***DITA Maps Manager** view*). Then select whichever operation is appropriate for your needs.

XML Refactoring Wizard Dialog Box

When you select any of the operations, Oxygen XML Editor proceeds to the **XML Refactoring Wizard**. If you used the ***Multiple Documents At Once Method***, the wizard page allows you to choose a scope for the operation and some filtering options:

- **Scope** - Select from a variety of options to define the scope for which resources will be affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, **Current DITA map hierarchy**, or just the **Current file**.

- **Filters** section
  - **Include files** - Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).
  - **Restrict to known XML file types only** - Excludes non-XML file types from the operation.
  - **Look inside archives** - If this option is selected, the scope of the operation will include files inside archives.

If you used the ***Single Document Method***, the scope will be the current file so the scope and filtering options are not displayed.

You can then use one of the following buttons to proceed with the operation:

Preview

You can use the **Preview** button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

Warning: It is always recommended to use the **Preview** button to make sure the operation is not going to do something unexpected and after you click the **Finish** button, any **Undo** action will only revert changes on the current document.

Finish

When you use the **Finish** button, behind the scenes Oxygen XML Editor maps the structure of the previous DITA document type to a structure that fits the new type. In some cases, especially when the previous structure was very complex, the conversion might result in an invalid structure and some manual adjustments might be required.

Converting To and From DITA Specialization Document Types

If you use your own *DITA specialization document type*, you can modify the built-in, predefined conversion operations to work with your specialization by customizing the values of particular variables.

To use the conversion operations with your DITA specialization, follow these steps:

1. Locate the conversion stylesheets in the following directory: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/refactoring/dita-files-conversion-systlesheets`.
2. Each conversion operation has a stylesheet with the word **entrypoint** at the end of its name. Edit the appropriate `*-entrypoint.xsl` file (for example, to modify the **Convert to Task** operation, edit the `convert-resource-to-task-entrypoint.xsl` file).
3. Depending on whether you use a DTD, XML Schema, or Relax NG-based specialization, you can:
   a. Modify the values of the declared **root-element**, **public-literal-target**, and **system-literal-target** variables to match your specialization's DTD information.
   b. Modify the value of the declared **schema-location** variable to match the location of your specialization's XML schema.
   c. Modify the value of the declared **xml-model-location** variable to match your Relax NG specialization.
4. Save your changes to the stylesheet.
5. If you want to change the name of the operation that will be displayed in Oxygen XML Editor, follow these substeps:
   a. Locate the resource XML file for the same conversion operation in the following directory: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/refactoring/` (for example, for the **Convert to Task** operation, it is `convertResource2Task.xml`).
   b. Edit that XML file and change the **name** attribute to match whatever you want to be displayed for that operation (for example, `name="Convert to My DocType"`).
   c. Save your changes to the XML file.
6. Restart Oxygen XML Editor

Result: You should now see your changes when *accessing the conversion operations*.

Tip: You can also create your own customized refactoring operations. For more information, see *Custom Refactoring Operations* on page 710.

Refactoring XML Documents on page 703

Adding Images in DITA Topics

There are several ways to add images to a DITA topic, depending on if you want to create a figure element (with a title and caption), just insert an image inline, or if you want to use multiple versions of a graphic depending on the situation. For instance, you might want to use a specific image for each different product version or output media.

Adding an Image Inline with the Insert Image Dialog Box

Use the following procedure to add an image inline:

1. Place the cursor in the position you want the graphic to be inserted.
2. Select the **Insert Image** action. The **Insert Image** dialog box appears.

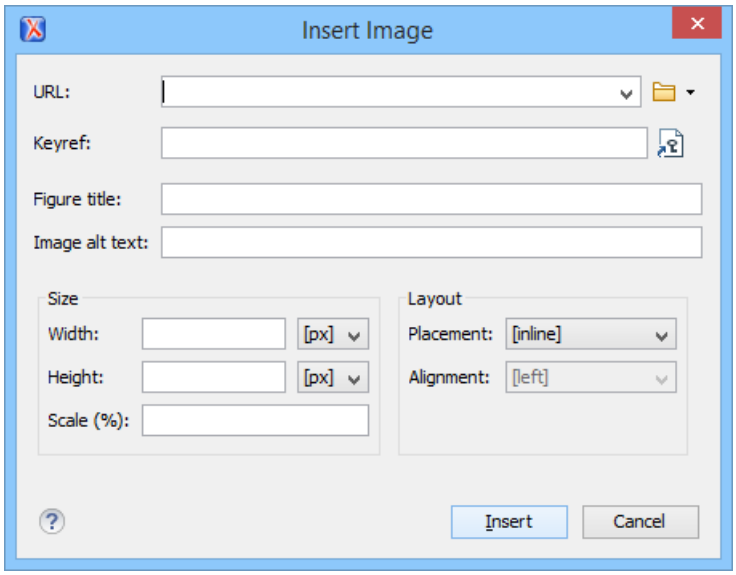

Figure 859: Insert Image Dialog Box

3. Configure the options in this dialog box and click **Insert**.

The **Insert Image** dialog box includes the following options for inserting images into a DITA document:

URL

Use this option to specify a URL for the image. It will insert the URL as the value of an `href` attribute inside an `image` element. You can type the URL of the image you want to insert or use the **Browse** drop-down menu to select an image using one of the following options:

- **Browse for local file** - Displays the **Open** dialog box to select a local file.
- **Browse for remote file** - Displays the ***Open URL*** *dialog box* to select a remote file.
- **Browse for archived file** - Opens the ***Archive Browser*** to select a file from an archive.
- **Browse Data Source Explorer** - Opens the ***Data Source Explorer*** to select a file from a connected data source.
- **Search for file** - Displays the **Find Resource** dialog box to search for a file.

Keyref

You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that presents the list of keys available in the selected *root map*. Use this dialog box to insert the selected key as the value of a `keyref` attribute inside an `image` element. All keys that are presented in the dialog box are gathered from the *root map* of the current *DITA map*. Elements that have the `keyref` attribute set are displayed as links.

Note: If your defined keys are not listed in this dialog box, it is most likely trying to gather keys from the wrong *root map*. You can change the *root map* by using the **Change Root Map** link.

Figure title

Use this text box to insert a `title` and `image` element inside a `fig` element.

Alternate text

Use this text box to insert an `alt` element inside the `image` element.

Size

Use this section to configure the **Width** and **Height** of the image, or **Scale** the image. Specifying a value in these options inserts a `width`, `height`, and `scale` attribute, respectively.

Layout

Use the options in this section to insert `placement` and `align` attributes into the `image` element.

Adding an Image Inline with Drag/Drop (or Copy/Paste) Actions

You can drag images from your system explorer or the ***Project*** *view* and drop them into a DITA document (or copy and paste). This will insert the path of the image file as the value of the `href` attribute in a DITA `image` element:

```
<image href="../images/image_file.png"/>
```

Tip: To replace an image, just drag and drop a new image over the existing one. Oxygen XML Editor will automatically update the reference to the new image.

Adding an Image in a Figure Element

To add an image in a figure:

1. Add a `fig` element to your document at the appropriate place.
2. Add a `title` and/or `desc` element to the `fig` element, according to your needs.
3. *Add an image element* to the `fig` element.

Note: The `fig` element has a number of other child elements that may be appropriate to your content. See the *DITA documentation* for complete information about the `fig` element.

Note: The order in which the `image`, `title`, and `desc` content are presented in output is determined by the output transformation. If you want to change how they are output, you may have to modify the output transformation, rather than your source content.

Related Information:

Image Maps in DITA on page 624
Floating Images in DITA Topics for PDF or XHTML Output on page 1829

Floating Images in DITA Topics for PDF or XHTML Output

Oxygen XML Editor provides the possibility of floating an image to the left or right of blocks of content in DITA topics for both PDF and XHTML output.

To float an image, you simply need to set the `outputclass` attribute on the `image` element. The possible values are:

- **float-left**
- **float-right**

For example, the following DITA structure will present the image to the right of the paragraph content in the output:

```
<p><image href="../../images/Lilac.jpg" scale="45" outputclass="float-right"/>
  <b>Lilac</b> (<b>Syringa</b>) is a genus of about 20–25 species of flowering plants
  in the olive family (<b>Oleaceae</b>), native to Europe and Asia.
</p>
```

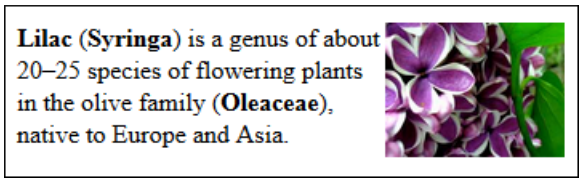

Figure 860: Image Floated to the Right

Adding Video, Audio, and Embedded HTML Resources in DITA Topics

You can insert references to media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics. The media resources can be played directly in **Author** mode and in all HTML5-based outputs. There is a toolbar button ( ) that allows you to insert and configure a reference to the media resource. You can also drag media files from your system explorer or the ***Project*** *view* and drop them into your documents (or copy and paste them).

Table 80: Supported Media Types

Media	Description	Type	Supported Size Properties
mp3	Moving Picture Experts Group Layer-3 Audio	audio	Width
wav	Windows Wave	audio	Width
pcm	Pulse Code Modulation	audio	Width
m4a	Moving Picture Experts Group Layer-4 Audio	audio	Width
aif	Audio Interchange Format	audio	Width
mp4	Moving Picture Experts Group Layer-4 Video	video	Width & Height
flv	Flash Video	video	Width & Height
m4v	Itunes Video File	video	Width & Height
avi	Audio Video Interleaved	video	Width & Height
embedded video (such as YouTube or Vimeo)	Embedded Iframe Code	iframe	Width & Height

Adding a Media Resource

To insert a media resource in a DITA document, use the following procedure:

1. Place the cursor at the location where you want the media resource.
2. Select the **Insert Media Resource** action from the toolbar. The **Insert Media** dialog box appears.

   Note: You can also drag media files from your system explorer or the ***Project*** *view* and drop them into your documents (or copy and paste them). Note that this method will bypass the **Insert Media** dialog box, so if you need to adjust the size you will need to adjust the `width` or `height` attributes manually.

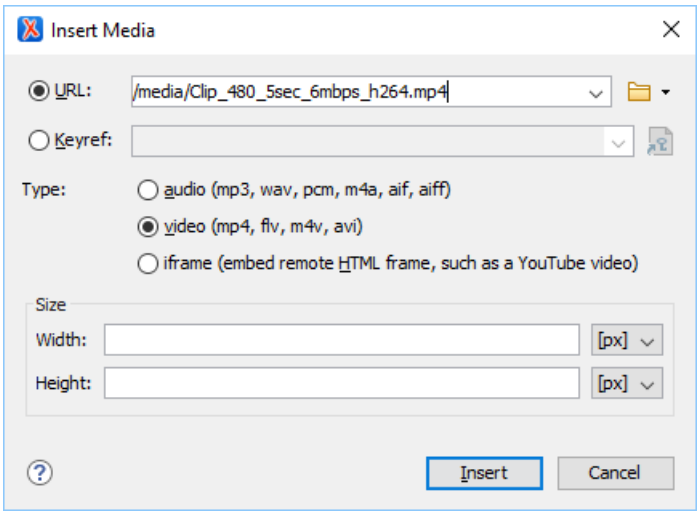

Figure 861: Insert Media Dialog Box

3. Configure the options in this dialog box and click **Insert**.

   The **Insert Media** dialog box includes the following options:

   URL

   Use this option to specify a URL for a media resource. It will insert the URL as the value of a `data` attribute of an `object` element. You can type the URL of the resource you want to insert or use the **Browse** drop-down menu to select it.

   Keyref

   You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that presents the list of keys available in the selected *root map*. Use this dialog box to insert the selected key as the value of the `datakeyref` attribute of an `object` element. All keys that are presented in the dialog box are gathered from the *root map* of the current *DITA map*.

   Tip: If your defined keys are not listed in this dialog box, it is most likely trying to gather keys from the wrong *root map*. You can change the *root map* by using the **Change Root Map** link.

   Type

   Oxygen XML Editor detects and automatically selects the media type based upon the specified resource in the *URL field*. You can manually change the type, but keep in mind that in the publishing stage the *object element is converted to an HTML5 element* based upon the type selected here. You can choose between: **audio**, **video**, or **iframe**.

   Size

   Use this section to configure the **Width** and **Height** of the frame for the media resource. Specifying a value in these options inserts a `width` and `height` attribute, respectively. For audio clips, only the **Width** can be adjusted.

Result in Author Mode: A reference to the specified video, audio, or embedded HTML frame is inserted in an `object` element and it is rendered in **Author** mode so that it can be played directly from there.

Result in Output: In the publishing stage, the `object` element is converted to an HTML5 element so that it can be rendered properly and played in all HTML5-based outputs.

- **Videos** - The `object` element is converted to an HTML5 `video` element.
- **Audio Clips** - The `object` element is converted to an HTML5 `audio` element.
- **Embedded HTML Frames** - The `object` element is converted to an HTML5 `iframe` element.

Tip: There is an even faster way of inserting an embedded video (such as a YouTube or Vimeo). If you copy the embed code from the source (for example, you can right-click on a YouTube video and select **Copy embed code**), you can then paste the contents of the clipboard in the ***URL** field* and the ***Type*** will automatically be set on **iframe**, while the ***Width** and **Height*** will be populated according to the detected size, and an `allowfullscreen`

parameter will automatically be added (set the value of this parameter to **true** to allow videos to play in full screen mode once the document is converted to XHTML output).

Inserting Media in HTML Outputs That Do Not Support Embedded Media

For certain types of HTML output (for example, CHM) that do not support embedded media (such as videos or audio files), Oxygen XML Editor provides a parameter that can be set in the transformation scenario to present the media object as a plain link in the output.

This can be achieved by following these steps:

1. *Edit the DITA transformation scenario* for the output type that does not support embedded objects (for example, **DITA Map CHM**).
2. Go to the ***Parameters** tab* and click the **New** button to add a new parameter.
3. For the **Name**, enter: **com.oxygenxml.xhtml.linkToMediaResources**.
4. For the **Value**, enter: **true**.
5. Click **OK** and continue on to run the transformation.

   Result: The media object will appear in the output as a plain link instead of an embedded object.

For more information, see the following video demonstration:

Adding Images in DITA Topics on page 1828
Adding Video and Audio Objects in DITA WebHelp Output on page 1182

Image Maps in DITA

Oxygen XML Editor includes support for **image maps** in DITA documents through the use of the `imagemap` element. This feature provides an easy way to create hyperlinks in various areas within an image without having to divide the image into separate image files. The visual **Author** editing mode includes an **Image Map Editor** that helps you to easily create and configure image maps.

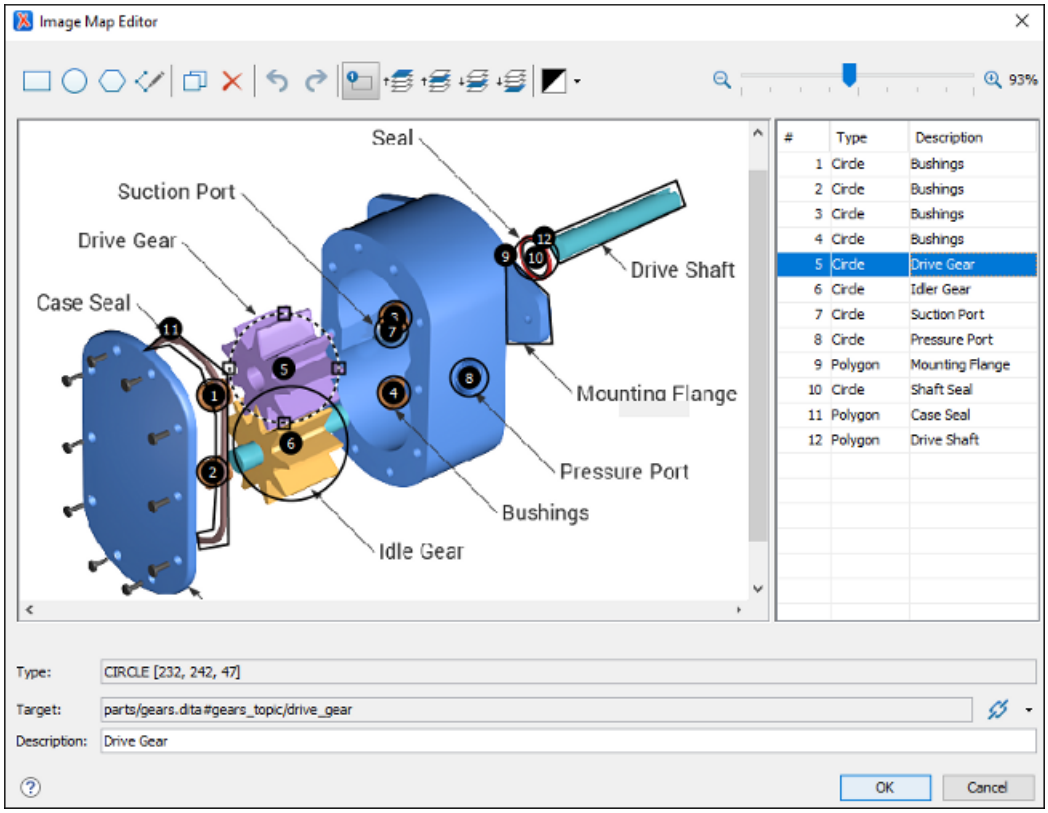

Figure 862: Image Map Editor in DITA

Image Map Editor Interface in DITA

The interface of the **Image Map Editor** consists of the following sections and actions:

Toolbar

 **New Rectangle**

Use this button to draw a rectangular shape over an area in the image. You can drag any of the four points to adjust the size and shape of the rectangle.

 **New Circle**

Use this button to draw a circle over an area in the image. You can drag any of the four points to adjust the size of the circle.

 **New Polygon**

Use this button to draw a polygon shape over an area in the image. This actions opens a dialog box that allows you to select the number of points for the polygon. You can drag any of the points to adjust the size and shape of the polygon.

 **New Free Form Shape**

Use this button to draw a free form shape over an area in the image. After selecting this button, left-click anywhere in the image to place the first point of your shape. Then move the cursor to the location of the next desired point and left-click to place the next point, and so on. To complete the shape (area), click the first point again and a line will automatically be added from the last point that was added, or simply double-click the last point to automatically add the line from the last point back to the first.

 **Duplicate**

Use this button to create a duplicate of the currently selected shape.

 **Delete**

Use this button to delete the currently selected shape.

 **Undo**

Use this button to undo the last action.

 **Redo**

Use this button to redo the last action that was undone.

 **Show/Hide Numbers**

Use this button to toggle between showing or hiding the numbers for the shapes.

 **Bring Shape to Front**

Use this button to bring the currently selected shape forward to the top layer.

 **Bring Shape Forward**

Use this button to bring the currently selected shape forward one layer.

 **Send Shape Backward**

Use this button to send the currently selected shape back one layer.

 **Send Shape to Back**

Use this button to send the currently selected shape back to the bottom layer.

 **Color Chooser**

Use this drop-down menu to select a color scheme for the lines and numbers of the shapes.

 **Zoom Slider**

Use this slider to zoom the image in or out in the main image pane.

Image Pane

This main Image Pane is where you work with shapes to add hyperlinks to multiple areas within an image. The editing mechanisms that are supported in the Image Pane include the following:

Mouse Controls and Keyboard Shortcuts

- Use the mouse to select and move shapes around in the image pane. It is easy to see which shape is selected in this image pane because the border of the selected shape changes from a solid line to a dotted one.
- You can also drag any of the points of a selected shape to adjust its size and shape.
- You can hold down the **Ctrl** key to select multiple shapes and then move them simultaneously.
- You can also move shapes by using the arrow keys on your keyboard. In addition, you can hold down **Shift** while using the arrow keys to move the shape farther or **Alt** to move it 1 pixel at a time.

Contextual Menu Actions Available in the Image Pane

You can right-click the shapes, points, or anywhere in the Image Pane to invoke the contextual menu where the following actions are available:

Add Point

Adds a point to *Polygon* or *Free Form* shapes.

Remove Point

Removes the current point from *Polygon* or *Free Form* shapes.

Duplicate

Create a duplicate of the currently selected shape.

Delete

Delete the currently selected shape.

New Rectangle

Creates a rectangular shape over an area in the image. You can drag any of the four points to adjust the size and shape of the rectangle.

New Circle

Creates a circle over an area in the image. You can drag any of the four points to adjust the size of the circle.

New Polygon

Creates a polygon shape over an area in the image. This actions opens a dialog box that allows you to select the number of points for the polygon. You can drag any of the points to adjust the size and shape of the polygon.

Undo

Use this action to undo the last action.

Redo

Use this action to redo the last action that was undone.

Shape Table

The table at the right of the *Image Pane* is a sequential list of all the areas (shapes) that have been added in the image. It shows their number, type, and description (if one has been added). If you select one of the entries in the table, the corresponding shape will be selected in the *Image Pane*.

Properties

Type

Displays information about the selected coordinate.

Target

Allows you to choose the target resource that you want the selected area (shape) to be linked to. Select a target by using the **Link** drop-down menu to the right of the text field. You can choose between the following types of links: **Cross Reference**, **File Reference**, or **Web Link**. All three types will open a dialog box that allows you to define the target resource. This linking process is similar to the normal process of *inserting links in DITA* by using the identical **Link** drop-down menu from the main toolbar.

When you click **OK** to finalize your changes in the **Image Map Editor**, an `xref` element will be inserted with either an `href` attribute or a `keyref` attribute. Additional attributes may also be inserted and their values depend on the target and the type of link. For details about the three types of links and their dialog boxes, see *Inserting a Link in Oxygen XML Editor* on page 1882.

Description

You can enter an optional description for the selected area (shape) that will be displayed in the ***Image Map Details** section* in **Author** mode and as a tooltip message when the end user hovers over the hyperlink in the output.

How to Create an Image Map in DITA

To create an image map on an existing image in a DITA document, follow these steps:

1. Right-click the image and select **Image Map Editor**.

   Result: This action will apply an *image map* to the current image and open the **Image Map Editor** dialog box.
2. Add hyperlinks to the image by selecting one of the shape buttons (**New Rectangle**, **New Circle**, or **New Polygon**).
3. Move the shape to the desired area in the image and drag any of the points on the shape to adjust its size or form. You can use the *other buttons on the toolbar* to adjust its layer and color, or to perform other editing actions.

   Tip: You can right-click any of the points, shapes, or anywhere in the Image Pane to access various helpful *contextual menu actions*. For example, the easiest way to remove a point is to right-click the point and select **Remove Point**.
4. With the shape selected, use one of the *linking options* in the **Link** drop-down menu to select a target resource (or enter its path in the ***Target*** text field).
5. (Optional) Enter a ***Description*** for the selected area (shape).
6. If you want to add more hyperlinks to the image, select a shape button again and repeat the appropriate steps.
7. When you are finished creating hyperlinks, click **OK** to process your changes.

Result: The *image map* is applied on the image and the appropriate elements and attributes are automatically added. In **Author** mode, the image map is now rendered over the image. If the image includes an `alt` element, its value will be displayed under the image. The following two buttons will also now be available under the image in **Author** mode:

- **Image Map Editor** - Click this button to open the **Image Map Editor**.
- **Image Map Details** - Click this button to expand a section that displays the details of the image map and allows you to change the shape and coordinates of the hyperlinked areas. Keep in mind that if you change the shape in this section, you also need to add or remove coordinates to match the requirements of the new shape.

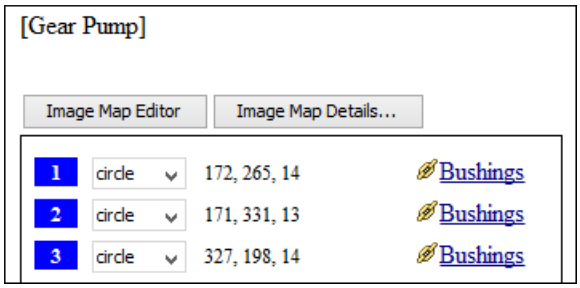

Figure 863: Image Map Details

How to Edit an Existing Image Map in DITA

To edit an existing image map, use any of the following methods:

- Simply double-click the image.
- Right-click the image and select **Image Map Editor**.
- Click the **Image Map Editor** button below the image.

All three methods open the **Image Map Editor** where you can make changes to the image map using the various features described above. You can also make changes to the XML structure of the image map in the **Text** editing mode.

You can also click the **Image Map Details** button below the image to expand a section that displays the details of the image map and allows you to change the shape and coordinates of the hyperlinked areas. Keep in mind that if you change the shape in this section, you also need to add or remove coordinates to match the requirements of the new shape.

Overlapping Areas

If shapes overlap one another in the **Image Map Editor**, the one on the top layer takes precedence. The number shown inside each shape represent its layer (if the numbers are not displayed, click the **Show/Hide Numbers** button on the ***Image Map Editor*** *toolbar*). To change the layer order for a shape, use the layer buttons on the ***Image Map Editor*** *toolbar* (, , ,).

If you insert a shape and all of its coordinates are completely inside another shape, the **Image Map Editor** will display a warning to let you know that the shape is entirely covered by a bigger shape. Keep in mind that if a shape is completely inside another shape, its hyperlink will only be accessible if its layer is on top of the bigger shape.

DITA 'imagemap' Element Specifications

Adding Images in DITA Topics on page 1828

Adding Tables in DITA Topics

You can use the **Insert Table** action on the toolbar or from the contextual menu to add a table in a DITA topic. By default, DITA supports four types of tables:

- *DITA Simple table model* - This is the most commonly used model for basic tables.
- *CALS table model (OASIS Exchange Table Model)* - This is used for more advanced functionality.
- *DITA Choice table model* - This is used within a `step` element in a DITA Task document to describe a series of optional choices that a user must make before proceeding.
- *DITA Properties table model* - This is used in DITA Reference documents to describe a property (for example, its type, value, and description).

If you are using a specialized DITA vocabulary, it may contain specialized versions of these table models.

Since DITA is a structured format, you can only insert a table in places in the structure of a topic where tables are allowed. The Oxygen XML Editor toolbar provides support for entering and editing tables. It also helps to indicate where you are allowed to insert a table or its components by disabling the appropriate buttons.

Inserting a Simple Table Model

To insert a **Simple** DITA table, select the **Insert Table** action on the toolbar or from the contextual menu (or the **Table** submenu from the **DITA** menu). The **Insert Table** dialog box appears. Select **Simple** for the table **Model**.

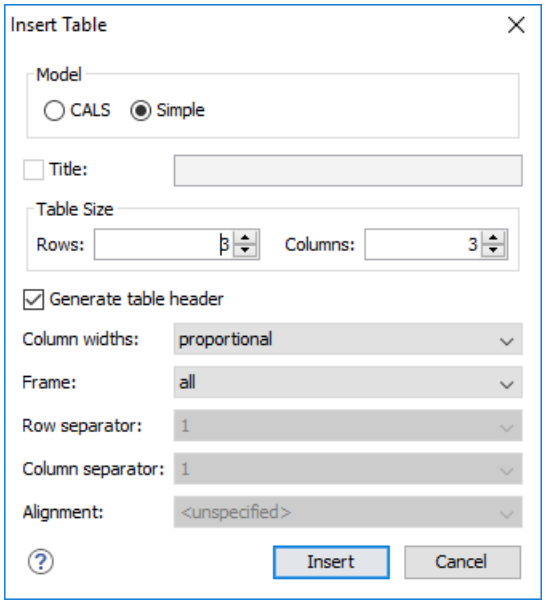

Figure 864: Insert Table Dialog Box - Simple Model

The dialog box allows you to configure the following options when you select the **Simple** table model:

Title

If this checkbox is selected, you can specify a title for your table in the adjacent text box.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Column widths

Allows you to specify the type of properties for column widths (`colwidth` attribute). You can choose one of the following properties for the column width:

- **proportional** - The width is specified in proportional (relative) units of measure. The proportion of the column is specified in a `relcolwidth` attribute with the values listed as the number of shares followed by an asterisk. The value of the shares are totaled and rendered as a percent. For example, `relcolwidth="1* 2* 3*"` causes widths of 16.7%, 33.3%, and 66.7%. When entering content into a cell in one column, the width proportions of the other columns are maintained. If you change the width by dragging a column in **Author** mode, the values of the `relcolwidth` attribute are automatically changed accordingly. By default, when you insert, drag and drop, or copy/paste a column, the value of the `relcolwidth` attribute is `1*`.
- **dynamic** - If you choose this option, the columns are created without a specified width. Entering content into a cell changes the rendered width dynamically. If you change the width by dragging a column in **Author** mode, a dialog box will be displayed that asks you if you want to switch to proportional or fixed column widths.

Frame

Allows you to specify a value for the `frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.

- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

Note: The options in the **Insert Table** dialog box for DITA documents are persistent, so changes made in one session will carry over to another.

When you click **Insert**, a simple table is inserted into your document at the current cursor position.

Inserting a CALS Table Model (OASIS Exchange Table)

To insert an OASIS Exchange Table (**CALS**), select the **Insert Table** action on the toolbar or from the contextual menu (or the **Table** submenu from the **DITA** menu). The **Insert Table** dialog box appears. Select **CALS** for the table **Model**. This model allows you to configure more properties than the *Simple* model.

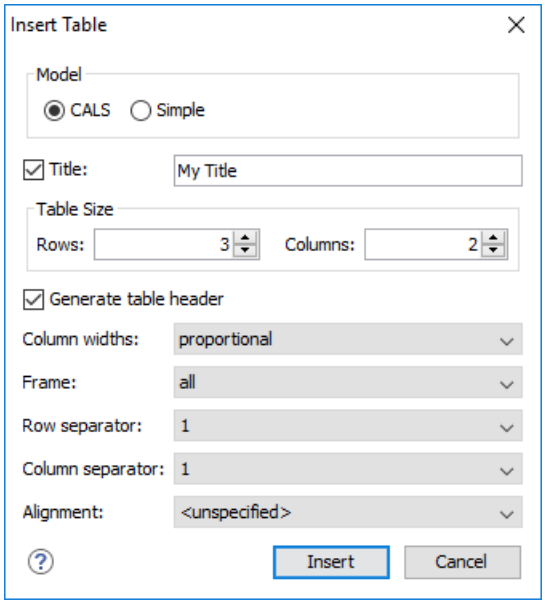

Figure 865: Insert Table Dialog Box - CALS Model

The dialog box allows you to configure the following options when you select the **CALS** table model:

Title

If this checkbox is selected, you can specify a title for your table in the adjacent text box.

Table Size

Allows you to choose the number of **Rows** and **Columns** for the table.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Column widths

Allows you to specify the type of properties for column widths (`colwidth` attribute). You can choose one of the following properties for the column width:

- **proportional** - The width is specified in proportional (relative) units of measure. The proportion of the column is specified in a `colwidth` attribute with the values listed as the number of shares followed by an asterisk. The value of the shares are totaled and rendered as a percent. For example, `colwidth="1* 2* 3*"` causes widths of 16.7%, 33.3%, and 66.7%. When entering content into a cell in one column, the width proportions of the other columns are maintained. If you change the width by dragging a column in **Author**

mode, the values of the `colwidth` attribute are automatically changed accordingly. By default, when you insert, drag and drop, or copy/paste a column, the value of the `colwidth` attribute is `1*`.

- **dynamic** - If you choose this option, the columns are created without a specified width (`colwidth` attribute). Entering content into a cell changes the rendered width dynamically. If you change the width by dragging a column in **Author** mode, a dialog box will be displayed that asks you if you want to switch to proportional or fixed column widths.
- **fixed** - The width is specified in fixed units. By default, the `pt` unit is inserted, but you can change the units in the **colspecs** (column specifications) section above the table or in **Text** mode. The following units are allowed: `pt` (points), `cm` (centimeters), `mm` (millimeters), `pi` (picas), `in` (inches).

Frame

Allows you to specify a value for the `frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

Row separator

Specifies whether or not to include row separators (`rowsep` attribute). The allowed values are: `0` (no separator) and 1 (include separators).

Column separator

Specifies whether or not to include column separators (`colsep` attribute). The allowed values are: `0` (no separator) and 1 (include separators).

Alignment

Specifies the alignment of the text within the table (`align` attribute). The allowed values are:

- **left** - Aligns the text to a left position.
- **right** - Aligns the text to a right position.
- **center** - Aligns the text to a centered position.
- **justify** - Stretches the line of text so that it has equal width.

  Note: The `justify` value cannot be rendered in **Author** mode, so you will only see it in the output.
- **char** - Aligns text to the leftmost occurrence of the value specified on the `char` attribute for alignment.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

Note: The options in the **Insert Table** dialog box for DITA documents are persistent, so changes made in one session will carry over to another.

When you click **Insert**, a CALS table is inserted into your document at the current cursor position.

When you insert a CALS table, you see a link for setting the `colspecs` (column specifications) of your table. Click the link to open the controls that allow you to adjust various column properties. Although they appear as part of the ***Author*** *mode*, the `colspecs` link and its controls will not appear in your output. They are just there to make it easier to adjust how the columns of your table are formatted.

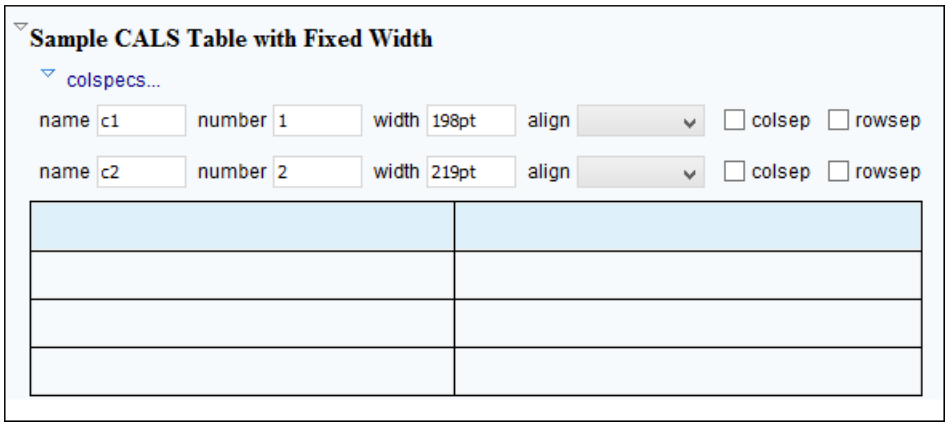

Figure 866: CALS Table in DITA

Inserting a Choice Table Model

To insert a **Choice** table within a `step` element in a DITA Task document, select the **Insert Table** action on the toolbar or in the **Insert** submenu from the contextual menu (or the **Table** submenu from the **DITA** menu), or select **choicetable** from the *Content Completion Assistant*. The **Insert Table** dialog box appears. Select **Simple** for the table **Model**.

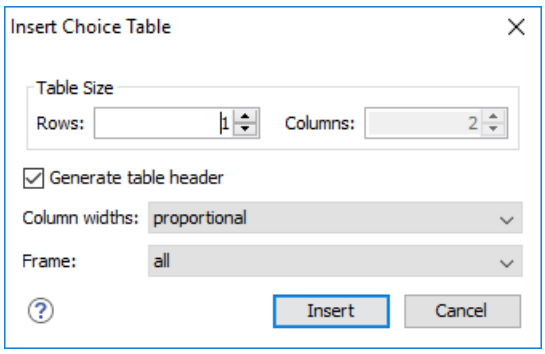

Figure 867: Insert Table Dialog Box - Choice Model

The dialog box allows you to configure the following options when you insert a *Choice* table model within a DITA Task:

Table Size

Allows you to choose the number of **Rows** and **Columns** for the table.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Column widths

Allows you to specify the type of properties for column widths (`colwidth` attribute). You can choose one of the following properties for the column width:

- **proportional** - The width is specified in proportional (relative) units of measure. The proportion of the column is specified in a `relcolwidth` attribute with the values listed as the number of shares followed by an asterisk. The value of the shares are totaled and rendered as a percent. For example, `relcolwidth="1* 2* 3*"` causes widths of 16.7%, 33.3%, and 66.7%. When entering content into a cell in one column, the width proportions of the other columns are maintained. If you change the width by dragging a column in **Author** mode, the values of the `relcolwidth` attribute are automatically changed accordingly. By default, when you insert, drag and drop, or copy/paste a column, the value of the `relcolwidth` attribute is `1*`.
- **dynamic** - If you choose this option, the columns are created without a specified width. Entering content into a cell changes the rendered width dynamically. If you change the width by dragging a column in

Author mode, a dialog box will be displayed that asks you if you want to switch to proportional or fixed column widths.

Frame

Allows you to specify a value for the `frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

When you click **Insert**, a *Choice* table is inserted into your DITA Task document at the current cursor position (within a `step` element).

Inserting a Properties Table Model

To insert a **Properties** table within a `refbody` element in a DITA Reference document, select the **Insert Table** action on the toolbar or in the **Insert** submenu from the contextual menu (or the **Table** submenu from the **DITA** menu), or select **properties(wizard)** from the *Content Completion Assistant*. The **Insert Table** dialog box appears. Select **Properties** for the table **Model**.

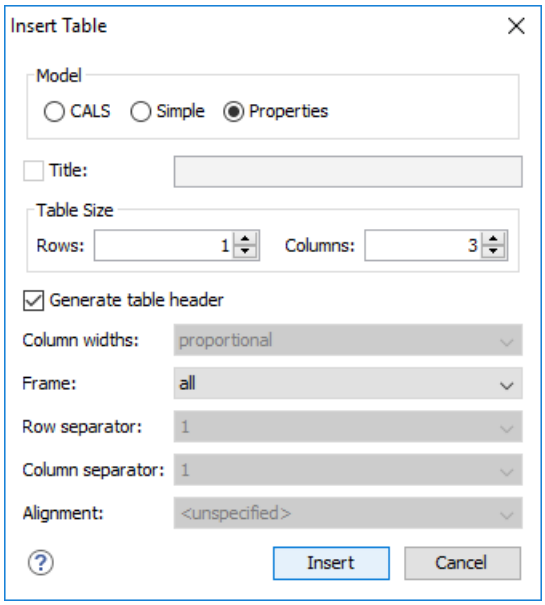

Figure 868: Insert Table Dialog Box - Properties Model

The dialog box allows you to configure the following options when you insert a *Properties* table model within a DITA Reference:

Table Size

Allows you to choose the number of **Rows** and **Columns** for the table.

Generate table header

If selected, an extra row will be inserted at the top of the table to be used as the table header.

Frame

Allows you to specify a value for the `frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

When you click **Insert**, a *Properties* table is inserted into your DITA Reference document at the current cursor position (within a `refbody` element).

Editing an Existing Table

You can edit the structure of an existing table using the table buttons on the toolbar (or in the contextual menu) to add or remove cells, rows, or columns, and to set basic table properties. Additional attributes can be used to fine-tune the formatting of your tables by using the ***Attributes*** *view* (**Window** > **Show View** > **Attributes**). See the *DITA documentation* for a full explanation of these attributes.

You can also use the ***Table Properties (Ctrl + T (Command + T on OS X))*** action from the toolbar or contextual menu (or **DITA** menu) to *modify many of the properties of the table*.

Also, remember that underneath the visual representation, both table models are really just XML. If necessary, you can edit the XML directly by switching to ***Text*** *mode*.

Editing Tables in Author Mode on page 594

DITA Table Layouts

Depending on the context, DITA accepts the following table layouts:

- *CALS table model*
- *Simple table model*
- *Choice table model*
- *Properties table model*

CALS Table Model Layout

The **CALS** table model allows for more flexibility and table customization than other models. When choosing a **CALS** table model from the **Insert Table** dialog box, you have access to more configurable properties. The layout of a **CALS** table includes a **colspecs** section that allows you to easily configure some properties without opening the **Table Properties** dialog box. For example, you can change the value of column widths (`colwidth` attribute) or the text alignment (`align` attribute). Although they appear as part of the ***Author*** *mode*, the `colspecs` link and its controls will not appear in your output. They are just there to make it easier to adjust how the columns of your table are formatted.

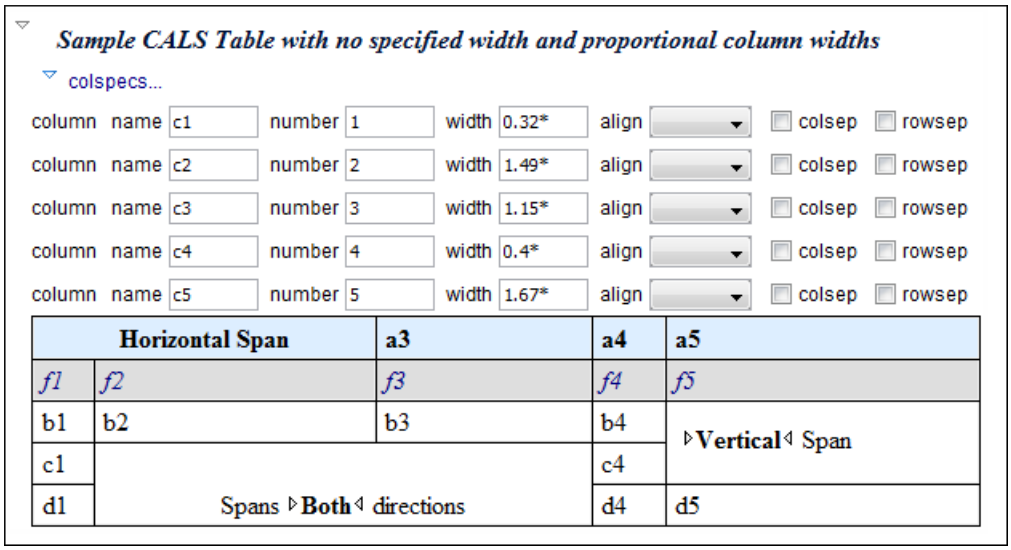

Figure 869: CALS Table in DITA

Simple Table Model Layout

When choosing a **Simple** table model from the **Insert Table** dialog box, you only have access to configure a few properties. For example, you can choose the number of rows and columns, specify values for frames, and choose from a few types of properties for the column width. The layout of this type of table is very simple, as the name suggests.

Header 1	Header 2
Column 1	Column 2

Figure 870: DITA Simple Table

Choice Table Model Layout

A **Choice** table model is used within a `step` element in a DITA Task document to describe a series of optional choices that a user must make before proceeding. The `choicetable` element is a useful device for documenting options within a single step of a task. You can insert *Choice* tables in DITA Task documents either by selecting **choicetable** from the *Content Completion Assistant* (within a `step` element) or by using the **Insert Table** action on the toolbar or from the contextual menu). The options and layout of a *Choice* table is similar to the *Simple* table model.

Option	Description
Opt A	
Opt B	
Opt C	

Figure 871: DITA Choice Table

Properties Table Model Layout

A **Properties** table model is used within a `refbody` element in a DITA Reference document to describe a property (for example, its type, value, and description). You can insert *Properties* tables in DITA Reference documents either by selecting **properties(wizard)** from the *Content Completion Assistant* (within a `refbody` element) or by using the **Insert Table** action on the toolbar (or from the contextual menu) and selecting **Properties** for the **Model**. The layout of a *Properties* table is very simple. It allows for a maximum of 3 columns (typically for property type, value, and description) and the only options available are for whether or not you want a header row and for specifying frames (borders).

Property Type	Property Value	Property Description
A	B	C

Figure 872: DITA Properties Table

Table Validation in DITA

Oxygen XML Editor reports table layout problems that are detected in manual or automatic validations. When you validate a *DITA map* with the  **Validate and Check for Completeness** action, if the ***Report table layout problems*** *option is selected in the* ***DITA Map Completeness Check*** *dialog box*, table layout problems will be reported in the validation results. The types of errors that may be reported for DITA table layout problems include:

CALS Tables

- A row has fewer cells than the number of columns detected from the table `cols` attribute.
- A row has more cells than the number of columns detected from the table `cols` attribute.
- A cell has a vertical span greater than the available rows count.
- The number of `colspecs` is different than the number of columns detected from the table `cols` attribute.
- The number of columns detected from the table `cols` attribute is different than the number of columns detected in the table structure.
- The value of the `cols`, `rowsep`, or `colsep` attributes are not numeric.
- The `namest`, `nameend`, or `colname` attributes point to an incorrect column name.

Simple or Choice Tables

- A row has fewer cells than the number of table columns.

Editing Table Properties in DITA

To customize the look of a table in DITA, place the cursor anywhere in a table and invoke the  **Table Properties (Ctrl + T (Command + T on OS X))** action from the toolbar or the **Table** submenu of the contextual menu (or **DITA** menu). This opens the **Table properties** dialog box.

The **Table properties** dialog box allows you to set specific properties to the table elements. The options that are available depend on the context and location within the table in which the action was invoked.

Note: Some properties allow the following special values, depending on the context and the current properties or values:

- **<not set>** - Use this value if you want to remove a property.
- **<preserve>** - If you select multiple elements that have the same property set to different values, you can choose this value to keep the values that are already set. In some cases it can also be used to keep the current non-standard value for a particular property.

Edit Table Properties for a CALS Table Model

For a **CALS** table model, the **Table properties** dialog box includes four tabs of options:

- **Table** tab - The options in this tab apply to the entire table.
- **Row** tab - The options in this tab apply to the current row or selection of multiple rows. A message at the bottom of the tab tells you how many rows will be affected.
- **Column** tab - The options in this tab apply to the current column or selection of multiple columns. A message at the bottom of the tab tells you how many columns will be affected.
- **Cell** tab - The options in this tab apply to the current cell or selection of multiple cells. A message at the bottom of the tab tells you how many cells will be affected.

The options in four tabs include a **Preview** pane that shows a representation of the modification.

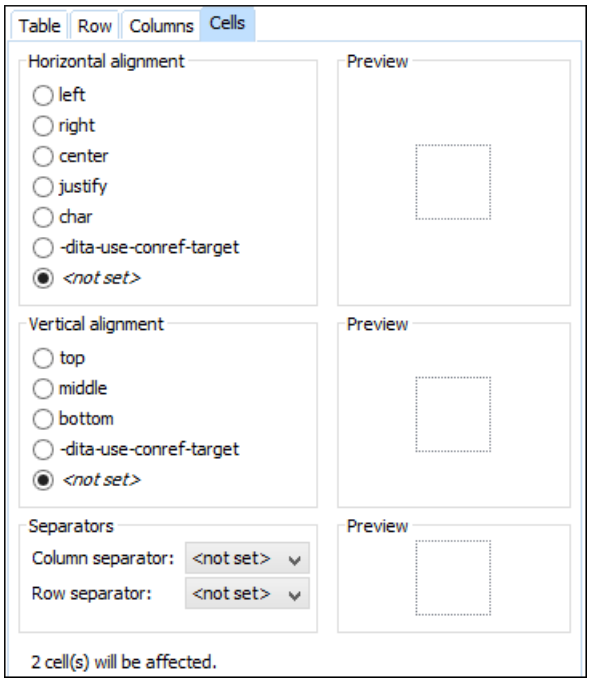

Figure 873: Table Properties Dialog Box with Cell Tab Selected (DITA CALS Table Model)

The options in the four tabs include the following:

Horizontal alignment (Available in the Table, Column, and Cell tabs)

Specifies the horizontal alignment of text within the current table/column/cell or selection of multiple columns/cells (`align` attribute). The allowed values are as follows:

- **left** - Aligns the text to a left position.
- **right** - Aligns the text to a right position.
- **center** - Aligns the text to a centered position.
- **justify** - Stretches the line of text so that it has equal width.

  Note: The `justify` value cannot be rendered in **Author** mode, so you will only see it in the output.
- **char** - Aligns text to the leftmost occurrence of the value specified on the `char` attribute for alignment.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

Vertical alignment (Available in the Row and Cell tabs)

Specifies the vertical alignment of text within the current row/cell or selection of multiple rows/cells (`valign` attribute). The allowed values are as follows:

- **top** - Aligns the text at the top of the cell.
- **middle** - Aligns the text in a vertically centered position.
- **bottom** - Aligns the text at the bottom of the cell.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

Column separator (Available in the Table, Column, and Cell tabs)

Specifies whether or not to include column separators (borders/grid lines) in the form of the `colsep` attribute. The allowed values are: `0` (no separator) and 1 (include separators).

Row separator (Available in all four tabs)

Specifies whether or not to include row separators (borders/grid lines) in the form of the `rowsep` attribute. The allowed values are: `0` (no separator) and 1 (include separators).

Frame (Available only in the Table tab)

Allows you to specify a value for the `frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

Edit Table Properties for a Simple, Choice, or Properties Table Model

For a *Simple*, *Choice*, *Properties* table model, the **Table properties** dialog box only allows you to edit a few options.

Table tab

Frame

Allows you to specify a value for the `frame` attribute. It is used to specify where a border should appear in the table. The allowed values are as follows:

- **none** - No border will be added.
- **all** - A border will be added to all frames.
- **top** - A border will be added to the top frame.
- **topbot** - A border will be added to the top and bottom frames.
- **bottom** - A border will be added to the bottom frame.
- **sides** - A border will be added to the side frames.
- **-dita-use-conref-target** - Normally, when using a `conref`, the values of attributes specified locally are preserved. You can choose this option to override this behavior and pull the value of this particular attribute from the `conref` target. For more information, see *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/ditauseconreftarget.html*.

Row tab (not available for *Properties* tables)

Row type

Allows you change the row to a body or header type of row.

Related Information:

Adding Tables in DITA Topics on page 603
Editing Tables in Author Mode on page 594

Adding MathML Equations in DITA Topics

You can add MathML equations in a DITA document using one of the following methods:

- Embed MathML directly into a DITA topic. You can start with the **Framework templates / DITA / topic / Composite with MathML** document template, available from the **New** file action wizard.
- Reference an external MathML file as an image, using the **Insert Image** action that is available on the DITA toolbar (or from the **DITA** > **Insert** menu).

Note: MathML equations contained in DITA topics can only be published out-of-the-box in PDF using the **DITA PDF** transformation scenario. For other publishing formats, you must employ additional customizations for handling MathML content.

DITA Author Mode Actions

A variety of actions are available in the DITA *framework* that can be added to the **DITA** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

DITA Toolbar Actions

The following default actions are readily available on the **DITA (Author Custom Actions)** toolbar when editing in **Author** mode (by default, most of them are also available in the **DITA** menu and in various submenus of the contextual menu):

Bold

Surrounds the selected text with a b tag. You can use this action on multiple non-contiguous selections.

Italic

Surrounds the selected text with an `i` tag. You can use this action on multiple non-contiguous selections.

Underline

Surrounds the selected text with a u tag. You can use this action on multiple non-contiguous selections.

Link Actions Drop-Down Menu

The following link actions are available from this menu:

Cross Reference

Opens the ***Cross Reference (xref)*** *dialog box* that allows you to insert a link to a target resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see *Linking in DITA Topics* on page 1881.

File Reference

Opens the ***File Reference*** *dialog box* that allows you to insert a link to a target file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. For more information, see *Linking in DITA Topics* on page 1881.

Web Link

Opens the ***Web Link*** *dialog box* that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. For more information, see *Linking in DITA Topics* on page 1881.

Related Link to Topic

Opens the ***Cross Reference (xref)*** *dialog box* that allows you to insert a link to a target resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see *Linking in DITA Topics* on page 1881.

Related Link to File

Opens the ***File Reference*** *dialog box* that allows you to insert a link to a target file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see *Linking in DITA Topics* on page 1881.

Related Link to Web Page

Opens the ***Web Link*** *dialog box* that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see *Linking in DITA Topics* on page 1881.

Insert Image

Opens the ***Insert Image*** *dialog box* that allows you to configure the properties of an image to be inserted into a DITA document at the cursor position.

Insert Media Resource

Opens the ***Insert Media*** *dialog box* that allows you to select and configure the properties of a media object to be inserted into a DITA document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted in an `object` element and it is rendered in **Author** mode so that it can be played directly from there.

Insert Section Drop-Down Menu

The following insert actions are available from this menu:

Insert Section

Inserts a new `section` element in the document, depending on the current context.

Insert Concept

Inserts a new `concept` element, depending on the current context. Concepts provide background information that users must know before they can successfully work with a product or interface.

Insert Task

Inserts a new `task` element, depending on the current context. Tasks are the main building blocks for task-oriented user assistance. They generally provide step-by-step instructions that will help a user to perform a task.

Insert Topic

Inserts a new `topic` element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

Insert Reference

Inserts a new `reference` element, depending on the current context. A reference is a top-level container for a reference topic.

Insert Paragraph

Inserts a new paragraph at current cursor position.

Reuse Content

This action provides a mechanism for reusing content fragments. It opens the ***Reuse Content*** *dialog box* that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include *content references (conref)*, *content key references (conkeyref)*, or *key references to metadata (keyref)*.

Insert step or list item

Inserts a new list or step item in the current list type.

Insert Unordered List

Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content — text + markup — that is rendered inside a *block element*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Column After

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

DITA Menu Actions

In addition to the *DITA toolbar actions*, the following default actions are available in the **DITA** menu when editing in **Author** mode:

Reuse Content

This action provides a mechanism for reusing content fragments. It opens the ***Reuse Content*** *dialog box* that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include *content references (conref)*, *content key references (conkeyref)*, or *key references to metadata (keyref)*.

Push Current Element

Opens the ***Push current element*** *dialog box* that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

Edit Content Reference

This action is available for elements with a `conref` or `conkeyref` attribute. it opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`conref`/`conkeyref` and `conrefend` attributes). For more information, see *Reuse Content Dialog Box* on page 1864.

Replace Reference with content

Replaces the referenced fragment (`conref` or `conkeyref`) at the cursor position with its content. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location.

Remove Content Reference

Removes the content reference (`conref` or `conkeyref`) inside the element at the cursor position.

Create Reusable Component

Creates a reusable component from the selected fragment of text. For more information, see *Creating a Reusable Content Component* on page 1872.

Insert Reusable Component

Inserts a reusable component at cursor location. For more information, see *Inserting a Reusable Content Component* on page 1873.

Paste special submenu

This submenu includes the following special paste actions that are specific to the DITA *framework*:

Paste as content reference

Inserts a content reference (a DITA element with a `conref` attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The `conref` attribute will point to this ID value.

Paste as content key reference

Allows you to indirectly reference content using the `conkeyref` attribute. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps*. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the ***Root map** combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Paste as link

Looks for the first element with an ID value in the clipboard and inserts an `xref` that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

Paste as link (keyref)

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the ***Root map** combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Insert Column Before

Inserts a column before the current one.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Insert > Σ Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is *cut* and *pasted*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Browse DITA Style Guide

Opens the **DITA Style Guide Best Practices for Authors** in your browser and displays a topic that is relevant to the element at the cursor position. When editing DITA documents, this action is available in the contextual menu of the editing area (under the **About Element** sub-menu), in the **DITA** menu, and in some of the documentation tips that are displayed by the *Content Completion Assistant*.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

DITA Contextual Menu Actions

In addition to many of the *DITA toolbar actions* and the *general* ***Author*** *mode contextual menu actions*, the following DITA *framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Paste special submenu

This submenu includes the following special paste actions that are specific to the DITA *framework*:

Paste as content reference

Inserts a content reference (a DITA element with a `conref` attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The `conref` attribute will point to this ID value.

Paste as content key reference

Allows you to indirectly reference content using the `conkeyref` attribute. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps*. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the ***Root map*** *combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Paste as link

Looks for the first element with an ID value in the clipboard and inserts an `xref` that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

Paste as link (keyref)

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the ***Root map*** *combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

 **Delete Row(s)**

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

 **Delete Column(s)**

Deletes the table column located at cursor position or multiple columns in a selection.

 **Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

 **Split Cell**

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

 **Sort**

Sorts cells or list items in a table.

 **Table Properties**

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

Insert > Σ Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Reuse submenu

This submenu includes the following actions in regards to reusing content in DITA:

Push Current Element

Opens the ***Push current element*** *dialog box* that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

Edit Content Reference

This action is available for elements with a `conref` or `conkeyref` attribute. it opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`conref`/`conkeyref` and `conrefend` attributes). For more information, see *Reuse Content Dialog Box* on page 1864.

Replace Reference with content

Replaces the referenced fragment (`conref` or `conkeyref`) at the cursor position with its content. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location.

Remove Content Reference

Removes the content reference (`conref` or `conkeyref`) inside the element at the cursor position.

Create Reusable Component

Creates a reusable component from the selected fragment of text. For more information, see *Creating a Reusable Content Component* on page 1872.

Insert Reusable Component

Inserts a reusable component at cursor location. For more information, see *Inserting a Reusable Content Component* on page 1873.

Search References (Ctrl + Shift + G)

Finds the references to the `id` attribute value for the element at the current cursor position, in all the topics contained in the current *DITA map* (opened in the ***DITA Maps Manager*** *view*). If no references are found for the current element, a dialog box will be displayed that offers you the option of searching for references to its ancestor elements.

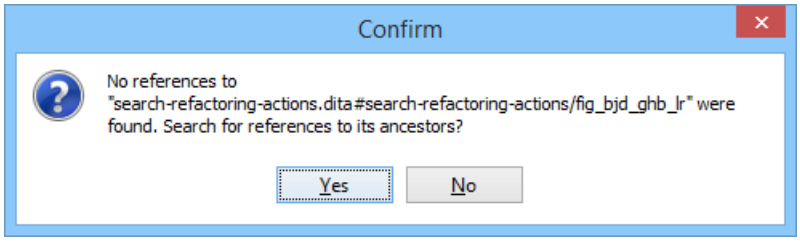

Figure 874: Search References to Ancestors Dialog Box

Show Key Definition

Available for elements that have a `conkeyref` or `keyref` attribute set (or elements with an ancestor element that has a `conkeyref` or `keyref` attribute). It computes the key name and opens the *DITA map* that contains the definition of the key with the element that defines that key selected.

About Element submenu

This submenu includes the following actions:

Style Guide

Opens the **DITA Style Guide Best Practices for Authors** in your browser and displays a topic that is relevant to the element at the cursor position. When editing DITA documents, this action is available in the contextual menu of the editing area (under the **About Element** sub-menu), in the **DITA** menu, and in some of the documentation tips that are displayed by the *Content Completion Assistant*.

Browse reference manual

Opens a reference to the documentation of the XML element closest to the cursor position in a web browser.

Go to Definition

Moves the cursor to the definition of the current element.

DITA Drag/Drop (or Copy/Paste) Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a DITA document that is edited in **Author** mode, creates a link to the dragged file (the `xref` DITA element with the `href` attribute) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the ***Project*** *view* and drop them into a DITA document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the DITA `image` element with an `href` attribute).

Working with Markdown Documents in DITA

Oxygen XML Editor includes some unique features that allow you to easily integrate Markdown documents in a DITA project. This is especially helpful for teams that have contributors who are familiar with the Markdown syntax, but they want their output to be generated from DITA projects. The integration between the Markdown editor and DITA includes actions to export or convert Markdown documents to DITA topics and the **DITA** tab in the *Preview* pane provides a visualization of how the topic will look after conversion.

Export Markdown as a DITA Topic

The Markdown editor includes an option to quickly convert the current Markdown document into a DITA topic. The **Export as DITA Topic** action is available in the contextual menu of the left-side text editor and the right-side *Preview* pane when the **DITA** tab selected.

The conversion creates a new XML file that is defined as a DITA topic and opens it in the **Text** editing mode. You can then work with the document as you would with any other DITA topic, although you may need to manually correct some issues where the parser could not properly map Markdown syntax to DITA markup.

Working with Markdown Documents in the DITA Maps Manager

Oxygen XML Editor has some specialized features that allow you to integrate Markdown documents directly into your DITA project using the ***DITA Maps Manager***. The following features are available for Markdown documents in the **DITA Maps Manager** view:

- **Insert Reference to Markdown Document** - You can use the **New**, **Reference**, and **Reference to the currently edited file** actions from the **Append Child**, **Insert Before**, or **Insert After** submenu when invoking the contextual menu in the **DITA Maps Manager** to insert a reference to a Markdown document at the selected location in the map. Markdown documents will be inserted as a topic reference (`topicref` element) with the `format` attribute set to `markdown`.
- **Validate Markdown Documents in DITA Maps** - When you use the **Validate and Check for Completeness** action from the **DITA Maps Manager** toolbar to check the integrity of the structure of a *DITA map*, Markdown documents that are referenced in the *DITA map* will be converted to DITA topics in the background and validated the same as any other DITA topic.
- **Transforming DITA Maps with Markdown Documents** - When transforming *DITA maps* that have Markdown documents referenced, the transformation will convert the Markdown documents to normal DITA output without you needing to manually convert the Markdown documents to DITA topics.
- **Manually Convert Markdown Documents to DITA Topics** - If you need to use DITA semantics that are not possible in Markdown syntax (such as content references, related links, and other DITA-specific syntax), you can manually convert the Markdown document into a DITA topic. To do so, right-click the Markdown document in the **DITA Maps Manager** and select **Refactoring** > **Convert Markdown to DITA Topic**. This will open a dialog box that allows you to configure options for converting the document to an XML file that is defined as a DITA topic.

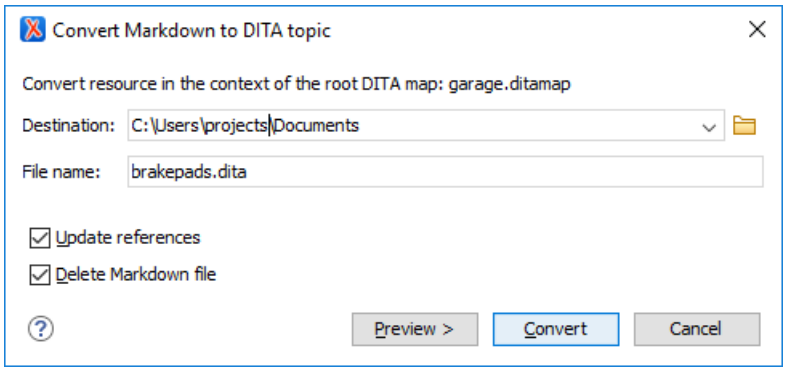

Figure 875: Convert Markdown to DITA Topic Dialog Box

This dialog box includes the following options:

Destination

The destination path for the new DITA topic.

File Name

Presents the current name and allows you to change it.

Update references

Select this option to update all references of the file in the *DITA map* and in the files referenced from the *DITA map*.

Delete Markdown file

If selected, the Markdown version of the file is deleted when the document is converted into a DITA file. If deselected (default value), when the document is converted into a DITA file, the original Markdown file is also preserved in its current location.

Preview

Select this button to display a preview of the changes Oxygen XML Editor is about to make.

Convert

Select this button to perform the conversion.

Tip: Oxygen XML Editor comes with a sample ditamap project for converting Markdown to DITA. Go to the ***Project*** *view*, open the `sample.xpr` project, and navigate to the `dita/markdown-dita` folder.

Working with Keys

DITA uses keys to insert content that may have different values in various circumstances. Keys provide a way to reference something indirectly. This can make it easier to manage and to reuse content in a number of ways.

You can think of keys as like renting a post office box. Instead of the mail going directly from the sender to your house, it now goes to the post office box. You then go to the post office box and bring the mail back to your house. If you move to a new house, your mail still gets to you because it comes to the same post office box. You do not have to send change of address cards to all the people who send you mail. Your mailbox address is the key that makes sure your mail always reaches you, even if you move.

Similarly, if you use keys in your content to reference other content, you do not have to update the source content to change the value of the key or what it points to. You just change the *definition of the key*.

Using Keys for Values

You can use keys to represent values that may vary depending on the type of output. For instance, you may have several products that share a common feature. When you want to describe that feature, you need a way to insert the name of the product, even though that name is different depending on which product the feature description is being used for. For more information, see *Working with Variable Text in DITA* on page 1873.

Assigning Keys to Topics

You can assign a key to a topic and use that key to reference that topic for various purposes, such as reuse or linking. As always, keys are defined in maps, so the key definition is done using the keys attribute of the `topicref` element:

```
<topicref href="quick-heat.dita" keys="feature.quick-heat"/>
```

The easiest way to assign keys to a topic (and insert the `topicref` element in its *DITA map*) is to use the ***Keys** tab in the **Edit Properties** dialog box*. In the ***DITA Maps Manager***, invoke the contextual menu on the topic for which you want to assign a key and select **Edit Properties**. Go to the **Keys** tab and enter the name of the key in the **Define keys** field.

Once a key is assigned to a topic, you can use it to reference that topic for various purposes:

- You can *create a link* to it using `<xref keyref="feature.quick-heat"/>`. This allows you to change the target of the link by changing the topic that is pointed to by the key (for example, by profiling).
- You can use it *in a map to create a reference to a topic* by key: `<topicref keyref="feature.quick-heat"`. This allows you to change which topic is inserted in the map by the build, by changing the topic that is pointed to by the key.
- You can use it to *insert a content reference*. In this case, the content reference uses the key to locate the topic to pull content from. It uses a `conkeyref` attribute: `<procedure conkeyref="feature.quick-heat/preheat-procedure"/>`. In this example, `feature.quick-heat` is the key, and `preheat-procedure` is the ID of a procedure within the topic for that key. Using this mechanism, you could have multiple versions of the preheat procedure in various topics and control which one is inserted by changing the topic that is pointed to by the key.

Assigning Keys to Graphics

You can assign a key to an image (using a map to point to the image file) and *insert the image using the key*.

Reusing DITA Content

Reusing content is one of the key features of DITA. DITA provides several methods for reusing content. Oxygen XML Editor provides support for each of these methods.

Reusing Topics in DITA Maps

A DITA topic does not belong to any one publication. You add a DITA topic to a publication by referencing it in a map. You can reference the same topic in multiple maps.

Reusing Content with References and Keys

DITA allows you to reuse content by referencing it in another topic. DITA provides several mechanisms for including content by reference (`conref`, `conkeyref`, `coderef`). A `conref` creates a direct reference to a specific element of another topic. A `conkeyref` creates a reference to a key, which then points to a specific element in another topic. The advantage of using a `conkeyref` is that you can change the element that is

included by changing the key reference. For example, since keys are defined in maps, if you include a topic in multiple maps, you can use a different key reference in each map. A `coderef` references an external file that contains literal code.

Oxygen XML Editor provides support for all of these mechanisms.

While the `conref` and `conkeyref` mechanisms can be used to reference any content element, it is considered best practice to only *conref* or *conkeyref* content that is specifically set and managed as reusable content. This practice helps reduce expensive errors, such as an author accidentally deleting the source element that other topics are including by `conref`. Oxygen XML Editor can help you create a reusable component from your current content.

Reusing Content with Reusable Components

DITA allows you to select content in a topic, create a reusable component from it and reference that component in other locations. Each reusable component is created as a separate file. Anytime the content needs to be edited, you only need to update it in the component file and all the locations in your topics that reference it will also be updated. This can help you to maintain continuity and accuracy throughout your documents.

Reusing Content with Variables

DITA allows you to replace the content of certain elements with a value that is pointed to by a key. This mechanism effectively means that you can create variables in your content, which you can then create multiple outputs by changing the value that the key points to. This is done by profiling the definition of the key value, or by substituting another map with a different key value.

Reusing Content with DITA 1.3 Concepts

DITA 1.3 allows you to use some advanced concepts to expand content reuse possibilities even further. *Key Scopes* (or scoped keys) allow you to reuse topics with variable content depending on the particular context and it maximizes reuse possibilities for keys. *Branch Filtering* allows you to reuse the same content that is profiled in multiple ways within the same publication, each time using a different filter.

Related Information:

Working with Keys on page 1856

Reusing DITA Topics in Multiple Maps

You can reuse an entire DITA topic simply by referencing it in multiple maps (or *multiple locations within the same map*) using one of the following procedures:

Reuse Topics Using the DITA Maps Manager

1. Make sure the *DITA map* is opened in the ***DITA Maps Manager***.
2. Add a reference to an existing topic by using one of the following methods (depending on your particular situation):
   a. If the topic already exists in this *DITA map*, do one of the following:
      - Simply drag the topic and press **Ctrl** (or **Alt** on OS X) at the new location within the map (or use the **Copy** and **Paste** contextual menu actions).
      - If the topic is the currently opened document in the main editor, determine the new location in the map (in the ***DITA Maps Manager***), right-click a parent or sibling topic, and select **Append Child** > **Reference to the currently edited file** or **Insert After** > **Reference to the currently edited file**.
   b. If the topic already exists in another *DITA map*, do one of the following:
      - Open the other map in the ***DITA Maps Manager***, right-click the topic, select **Copy**, switch back to the original *DITA map* in the **DITA Maps Manager**, determine the new location in the map, right-click a parent or sibling topic, and use one of the **Paste** contextual menu actions (**Paste**, **Paste Before**, or **Paste After**).

- If the topic is the currently opened document in the main editor, determine the new location in the map (in the ***DITA Maps Manager***), right-click a parent or sibling topic, and select **Append Child** > **Reference to the currently edited file** or **Insert After** > **Reference to the currently edited file**.

c. If the topic exists in the project, but has not yet been added to a *DITA map*, do one of the following:

- Right-click the topic in the ***Project** view* (or the file system), select **Copy**, switch to the ***DITA Maps Manager*** view, determine the new location in the map, right-click a parent or sibling topic, and use one of the **Paste** contextual menu actions (**Paste**, **Paste Before**, or **Paste After**).
- If the topic is the currently opened document in the main editor, determine the new location in the map (in the ***DITA Maps Manager***), right-click a parent or sibling topic, and select **Append Child** > **Reference to the currently edited file** or **Insert After** > **Reference to the currently edited file**.

3. If your topic uses a *key reference*, set up the appropriate *key definition in your map*.
4. If you want to define relationships between topics, other than those defined in the topics themselves, you can *add a relationship table to your map*.
5. When you have finished adding topics, check that your map is complete and that all topic links and keys resolve correctly. To do this *validation, click the* ***Validate and Check for Completeness*** *action* on the toolbar in the **DITA Maps Manager**.

Reuse Topics Using Author Mode Editor

1. *Open the DITA map* in the **Author** mode editor.
2. Add a reference to an existing topic by dragging it from the ***Project** view* (or the file system) and dropping it in the desired location in the *DITA map* opened in **Author** mode. You can also accomplish the same thing by using the **Copy** and **Paste** contextual menu actions.
3. If your topic uses a *key reference*, set up the appropriate *key definition in your map*.
4. If you want to define relationships between topics, other than those defined in the topics themselves, you can *add a relationship table to your map*.
5. When you have finished adding topics, check that your map is complete and that all topic links and keys resolve correctly. To do this *validation, click the* ***Validate and Check for Completeness*** *action* on the toolbar in the **DITA Maps Manager**.

Displaying Multiple References to the Same Topics

Whenever multiple references to the same topic are detected in the context of the current map in the ***DITA Maps Manager***, an indicator will appear in the top-right corner of the **Author** mode editor that shows the number of times the current topic is referenced in the *DITA map*. It also includes navigation arrows that allow you to jump to the next or previous reference in the **DITA Maps Manager**.

Working with Content References

The DITA `conref` feature (short for *content reference*) lets you insert a piece of source content by referencing it from its source. When you need to update that content, you only need to do it in one place.

There are several strategies for managing content references:

- *Reusable components* - With this strategy, you create a new file for each piece of content that you want to reuse and you insert references from the content of the reusable component files. For example, suppose that you have a disclaimer that needs to be included in certain sections of your documentation. You can create a reusable component that contains your disclaimer and reuse it as often as you need to. If the disclaimer ever needed to be updated, you only have to edit it in one file.
- *Single-source content references* - You may prefer to keep many pieces of reusable content in one file. For example, you might want to create a single file that contains all the actions that are available in various menus or toolbars for your software application. Then, wherever you need to describe or display an action in your documentation, you can reuse content from that single file by inserting content references. This strategy requires more setup than reusable components, but might make it easier to centrally managing the reused content and it allows for more flexibility in the XML structure of the reusable content.

- *Arbitrary content references* - Although it is not recommended, you can create content references amongst topics without storing the reusable content in components or a single file. This strategy might make it difficult to manage content that is reused and to maintain continuity and accuracy, since you may not have any indication that content you are editing is reused elsewhere.

Oxygen XML Editor creates a reference to the external content by adding a `conref` attribute to an element in the local document. The `conref` attribute defines a link to the referenced content, made up of a path to the file and the topic ID within the file. The path may also reference a specific element ID within the topic. Referenced content is not physically copied to the referencing file. However, by default Oxygen XML Editor displays it in **Author** mode as if it is there in the referencing file. If you do not want referenced content displayed, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Edit modes** > **Author**, and deselect the ***Display referenced content** option*.

Note: A reference also displays *tracked changes* and comments that are included in the source fragment. To edit these comments (or accept/reject changes) right-click the comment or tracked change and select **Edit Reference**.

Tip: To search for references made through a direct content references, use the **Search References** action from the contextual menu.

DITA Reusable Components View on page 1876

Creating a DITA Content Reference

DITA Content Reference

A DITA content reference, or `conref`, is one of the main *content reuse features of DITA*. It is a mechanism for re-using the same content in multiple topics (or even in multiple locations within the same topic).

For a `conref` to be created, the source content must have an `id` attribute that the `conref` can reference. Therefore, creating a `conref` requires that you add an `id` to the content to be reused before inserting a `conref` into the topic that reuses the referenced content.

Assigning an *ID* to the Referenced Content

To add an `id` to a DITA element in a topic, place the cursor on the element and select **Edit Attributes** from the contextual menu (or simply press **Alt+Enter**) to open the *in-place attribute editor*. Enter `id` as the **Name** of the attribute and a value of your choice in the **Value** field. You can also use *the **Attributes** view* to enter a value in the **id** attribute.

Note: The element may already have an `id`, since in some cases Oxygen XML Editor automatically generates an *ID* value when the `id` attribute is created.

Creating a Content Reference

To create a content reference (`conref`), follow these steps:

1. Make sure the element you want to reference has an *ID assigned to it*.
2. In ***Author** mode*, place the cursor at the location where you want the reused content to be inserted.
3. Select the **Reuse Content** action on the main toolbar (or from the **DITA** menu or **Reuse** submenu of the contextual menu). The ***Reuse Content** dialog box* is displayed.
4. In the **Location** field of the **Reuse Content** dialog box, select the topic that contains the element you want to reference. The elements that you can reference are presented in a table.
5. Select the **Target ID** of the element (or elements) from which you want to insert the content, and verify the content in the **Preview** pane. The `id` value of the element that you select is automatically added to the **Reference to (conref)** field.

6. Make any other selections you need in the ***Reuse Content*** *dialog box*. If you select multiple elements, the **Expand to (conrefend)** field is automatically filled with the `id` value of the last element in your selection.
7. Click **Insert** or **Insert and close** to create the content reference.

Using Copy/Paste Actions to Create a Content Reference

Oxygen XML Editor also includes support for creating content references with simple copy/paste actions. The copied content must be an entire DITA XML element with an ID attribute. Also, the location in the document where you paste the element must be valid, although as long as the ***Smart paste and drag and drop*** *option* is selected in the **Schema Aware** preferences page, if you try to paste it in an invalid location, Oxygen XML Editor will attempt to place it in a valid location, and may prompt you with one or more choices for where to place it.

To create a content reference (`conref`) using copy/paste actions, follow these steps:

1. Copy an entire DITA element that has an ID attribute assigned to it.
2. Place the cursor at a location where the copied element will be valid.
3. Select the **Paste as Content Reference** action from the  **Paste Special** submenu from the contextual menu.

Other Ways to Reuse Content

- You can use the ***Components*** *tab in the* ***DITA Reusable Components*** *view* to easily insert content references.
- An alternate way to reuse content is to use the Oxygen XML Editor ***Create Reusable Component*** and ***Insert Reusable Component*** actions (available in the **DITA** menu and the **Reuse** submenu of the contextual menu). They handle the details of creating an *ID* and *conref* and creates reusable component files, separate from your normal content files. This can help you manage your reusable content more effectively.
- You can also *insert reusable content using content key references*. This may also make reusable content easier to manage, depending on your particular situation and needs.
- Other topics in this section include information about more specialized or advanced ways or reusing content, such as *code references*, the *conref push mechanism*, *variable text*, *key scopes*, and *branch filtering*.

Creating a DITA Content Key Reference on page 1861

Creating a DITA Content Key Reference

DITA Content Key Reference

A DITA content key reference, or `conkeyref`, is a mechanism for inserting a piece of content from one topic into another. It is a version of the *DITA content reference mechanism* that uses *keys* to locate the content to reuse rather than direct references to topics that contain reused content.

As with a *conref*, a *conkeyref* requires that the element to be reused has an `id` attribute. It also requires the topic that contains the reusable content to be assigned a *key* in a map. As with all uses of keys, you can substitute multiple maps or *use profiling* to create multiple definitions of keys in a single map. This allows the same `conkeyref` to pull in content from various sources, depending on how your build is configured. This can make it easier to create and manage sophisticated content reuse scenarios.

Creating a Content Key Reference

To create a content key reference (`conkeyref`), follow these steps:

1. Make sure the topic that contains the reusable content is assigned a key in the *DITA map* and the element you want to reference has an *ID* assigned to it.
2. In ***Author*** *mode*, place the cursor at the location where you want the reused content to be inserted.

3. Select **Reuse Content** on the main toolbar (or from the **DITA** menu or **Reuse** submenu of the contextual menu). The ***Reuse Content*** *dialog box* is displayed.
4. Select the **Key** radio button for the content source and use the **Choose Key Reference** button to select the key for the topic that contains the reusable content (you can also select one from the drop-down list in the **Key** field). The elements that you can reference from the source are presented in the table in the middle of the **Reuse Content** dialog box.
5. Select the **Target ID** of the element (or elements) that you want to insert, and verify the content in the **Preview** pane. The `id` value of the element that you select is automatically added to the **Reference to (conkeyref)** field.
6. Make any other selections you need in the ***Reuse Content*** *dialog box*. If you select multiple elements, the **Expand to (conrefend)** field is automatically filled with the `id` value of the last element in your selection.
7. Click **Insert** or **Insert and close** to create the content reference.

Note: If you are using ***Text*** *mode*, when you insert a `conkeyref` attribute, after you enter the first quote (`conkeyref="`), the **Content Completion Assistant** will list all the defined keys that you can select from. Also, after you select the key, the **Content Completion Assistant** will then list the element IDs from the referenced topic, allowing you to insert an anchor. Note that this only works for local files.

Using Copy/Paste Actions to Create a Content Key Reference

Oxygen XML Editor also includes support for creating content key references with simple copy/paste actions. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps*. The copied content must be an entire DITA XML element with an ID attribute and the topic that contains the reusable content must have a key assigned in a *DITA map*. Also, the location in the document where you paste the element must be valid, although as long as the ***Smart paste and drag and drop*** *option* is selected in the **Schema Aware** preferences page, if you try to paste it in an invalid location, Oxygen XML Editor will attempt to place it in a valid location, and may prompt you with one or more choices for where to place it.

To create a content key reference (`conkeyref`) using copy/paste actions, follow these steps:

1. In the ***DITA Maps Manager*** *view*, make sure that the ***Root map*** *combo box* points to the correct map that stores the keys.
2. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the ***DITA Maps Manager***, select **Edit Properties**, and enter a value in the **Keys** field.
3. In a topic with an assigned key, copy an entire DITA element that has an ID attribute assigned to it.
4. Place the cursor at a location where the copied element will be valid.
5. Select the **Paste as Content Key Reference** action from the **Paste Special** submenu from the contextual menu.

Other Ways to Reuse Content

- You can use the ***Components*** *tab in the* ***DITA Reusable Components*** *view* to easily insert content key references.
- You can also *insert reusable content using content references (conref)*.
- Other topics in this section include information about more specialized or advanced ways or reusing content, such as *code references*, the *conref push mechanism*, *variable text*, *key scopes*, and *branch filtering*.

Reuse Content Dialog Box on page 1864
Working with Reusable Components on page 1872
Editing DITA Content References on page 1863
DITA Reusable Components View on page 1876
Creating a DITA Content Reference on page 1860

Editing DITA Content References

Oxygen XML Editor also includes some actions that allows you to quickly edit existing content references. When the element that contains a content reference (`conref` or `conkeyref`) is selected, the following actions are available in the **DITA** menu and the **Reuse** submenu of the contextual menu:

Edit Content Reference

This action is available for elements with a `conref` or `conkeyref` attribute. it opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`conref`/`conkeyref` and `conrefend` attributes). For more information, see *Reuse Content Dialog Box* on page 1864.

Replace Reference with content

Replaces the referenced fragment (`conref` or `conkeyref`) at the cursor position with its content. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location.

Remove Content Reference

Removes the content reference (`conref` or `conkeyref`) inside the element at the cursor position.

Converting Conrefs to Conkeyrefs

Oxygen XML Editor includes a DITA refactoring operation called **Convert conrefs to conkeyrefs** that will find all *content references* (that reference content outside the current document) and convert them to *content key references*. You can also use it to quickly convert all *content references* in the current document or multiple documents at once.

To access the **Convert conrefs to conkeyrefs** operation, use one of the following methods:

Single Document Method

With the document opened in the editor, right-click anywhere in the main editing pane (or right-click the topic reference in the ***DITA Maps Manager***), go to the **Refactoring** submenu, and choose **Convert conrefs to conkeyrefs**.

Multiple Documents At Once Method

Select **XML Refactoring** from the **Tools** menu (or from the **Refactoring** submenu when you right-click a document in the ***Project*** *view*or the ***DITA Maps Manager*** *view*). Then select **Convert conrefs to conkeyrefs** from the **DITA** section and click **Next**.

Either method will proceed to the **XML Refactoring Wizard**. If you used the ***Multiple Documents At Once Method***, the wizard page allows you to choose a scope for the operation and some filtering options:

- **Scope** - Select from a variety of options to define the scope for which resources will be affected by the operation. For example, you can choose to affect all resources in the **Project**, **All opened files**, **Current DITA map hierarchy**, or just the **Current file**.
- **Filters** section
  - **Include files** - Specifies files to be excluded from the operation. You can specify multiple files by separating them with commas and the patterns can include wildcards (such as ***** or **?**).
  - **Restrict to known XML file types only** - Excludes non-XML file types from the operation.
  - **Look inside archives** - If this option is selected, the scope of the operation will include files inside archives.

If you used the ***Single Document Method***, the scope will be the current file so the scope and filtering options are not displayed.

You can then use one of the following buttons to proceed with the operation:

Preview

You can use the **Preview** button to open a comparison panel where you can review all the changes that will be made by the refactoring operation before applying the changes.

Warning: It is always recommended to use the **Preview** button to make sure the operation is not going to do something unexpected and after you click the **Finish** button, any **Undo** action will only revert changes on the current document.

Finish

When you use the **Finish** button, the operation will be processed and all *content references* will be converted to *content key references* (either all *content references* in the current document or all *content references* in all of the documents specified in the scope). The file name for each converted document is used as the value for its new key. However, the operation does NOT automatically add the key to the *DITA Map*, so you still need to manually *define each key in your DITA map*.

Defining Keys in DITA Maps on page 1804

Reuse Content Dialog Box

The **Reuse Content** dialog box provides a mechanism for reusing content fragments. DITA `conref`, `conkeyref`, and `keyref` attributes can be used to insert references to reusable content. The `conref` attribute stores a reference to another element and is processed to replace the referencing element with the referenced element. The `conkeyref` attribute uses *keys* to locate the content to reuse rather than direct references to the topic that contains the reusable content. The `keyref` attribute also uses *keys* and can be used to indirectly reference metadata that may have different values in various circumstances.

Note: For a `conref` or `conkeyref`, to reference the content inside a DITA element, the source element must have an `id` attribute assigned to it. The element containing the content reference acts as a placeholder for the referenced element. For more details about DITA `conref` and `conkeyref` attributes, go to *https://www.oxygenxml.com/dita/1.3/specs/archSpec/base/conref.html*.

Note: For the purposes of using a `keyref`, keys are defined at map level and referenced afterwards. For more information about the DITA `keyref` attribute, go to *https://www.oxygenxml.com/dita/1.3/specs/langRef/attributes/thekeyrefattribute.html*.

Oxygen XML Editor *displays the referenced content* of a DITA content reference if it can resolve it to a valid resource. If you use URIs instead of local paths in your XML documents and your DITA OT transformation needs an *XML Catalog* to map the URIs to local paths, you need to *add the catalog to Oxygen XML Editor*. If the URIs can be resolved, the referenced content is displayed in **Author** mode and in the transformation output.

In **Author** mode, a references to reusable content (`conref`, `conkeyref`, or `keyref`) can easily be inserted at the cursor position by using the **Reuse Content** dialog box. It can be opened with any of the following methods:

- Go to **DITA** > **Reuse Content**.
- Click the **Reuse Content** action on the main toolbar.
- In the contextual menu of the editing area, go to **Reuse** > **Reuse Content**.

Your selection at the top of the dialog box for choosing the content source determines whether Oxygen XML Editor will insert a `conref`, `conkeyref`, or `keyref`.

If you select **Location** for the content source, a *content reference* (`conref`) will be inserted. If you select **Key** for the content source, keys will be used to insert a *content key reference* (`conkeyref`) or a *key reference* (`keyref`).

Content Reference (conref) Options Using the Reuse Content Dialog Box

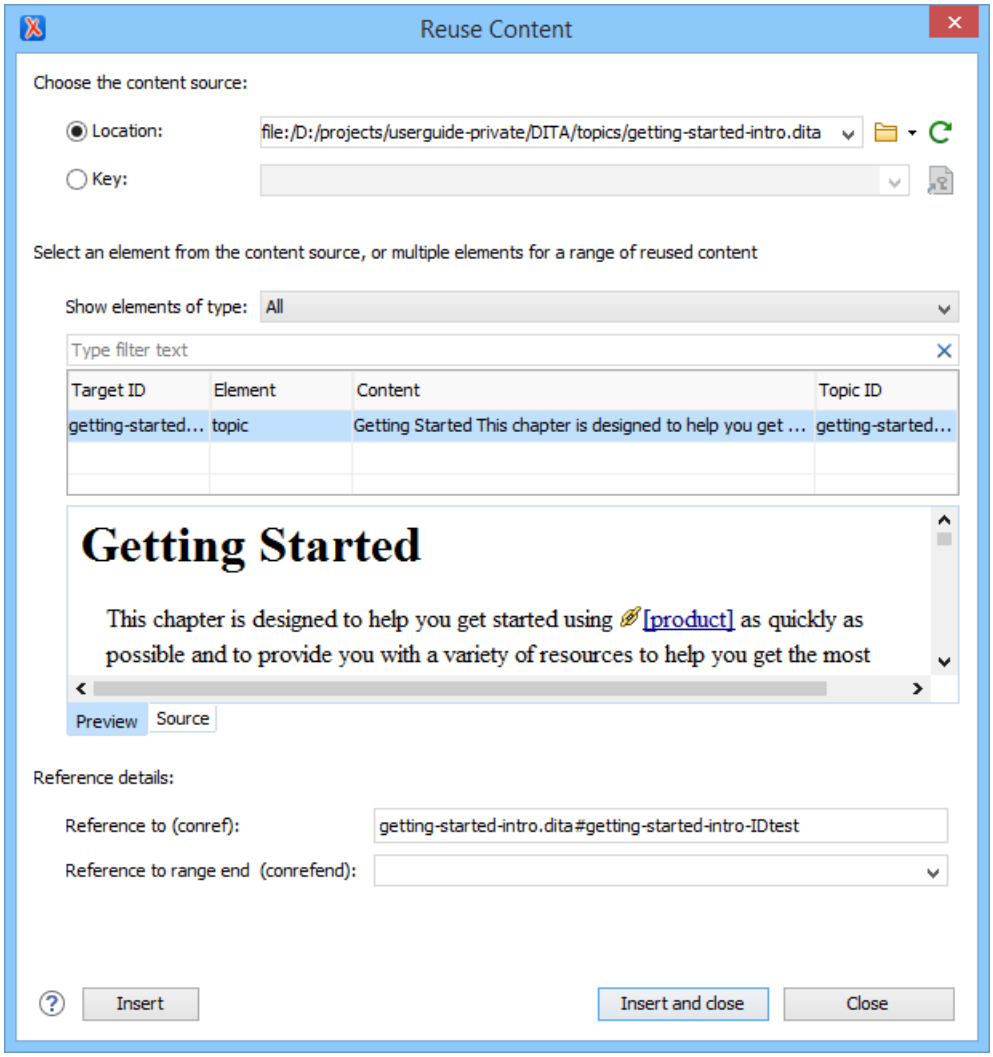

Figure 876: Reuse Content Dialog Box (with the Default Insert Content Reference Options Displayed)

Choose the content source Section

When **Location** is selected for the content source, a *content reference* (`conref`) will be inserted. Here you can specify the path of the topic that contains the content you want to reference.

The dialog box offers the following options:

Select an element from the content source Section

Show elements of type

You can use this drop-down list to select specific types of elements to be displayed in the subsequent table. This can help you narrow down the list of possible source elements that you can select.

Text Filter Field

You can also use the text filter field to narrow down the list of possible source elements to be displayed in the subsequent table.

Element Table

Presents all the element IDs defined in the source topic. Use this table to select the **Target ID** of the element that you want to reference. You can select multiple contiguous elements to reference a block of content.

Preview Pane

Displays the content that will be references. If you select multiple elements in the element table, the content from all the selected elements is displayed.

Source Pane

Displays the source code of the element to be referenced.

Reference details Section

Reference to (conref)

Oxygen XML Editor automatically fills this text field with the value of the `conref` attribute to be inserted. However, you can edit this value if need be.

Reference to range end (conrefend)

If you select multiple elements (of the same type) in the element table, Oxygen XML Editor automatically fills this text field with the `id` value of the last element in your selection. This value will be inserted as a `conrefend` attribute, defining the end of the `conref` range.

Content Key Reference (`conkeyref`) Options Using the Reuse Content Dialog Box

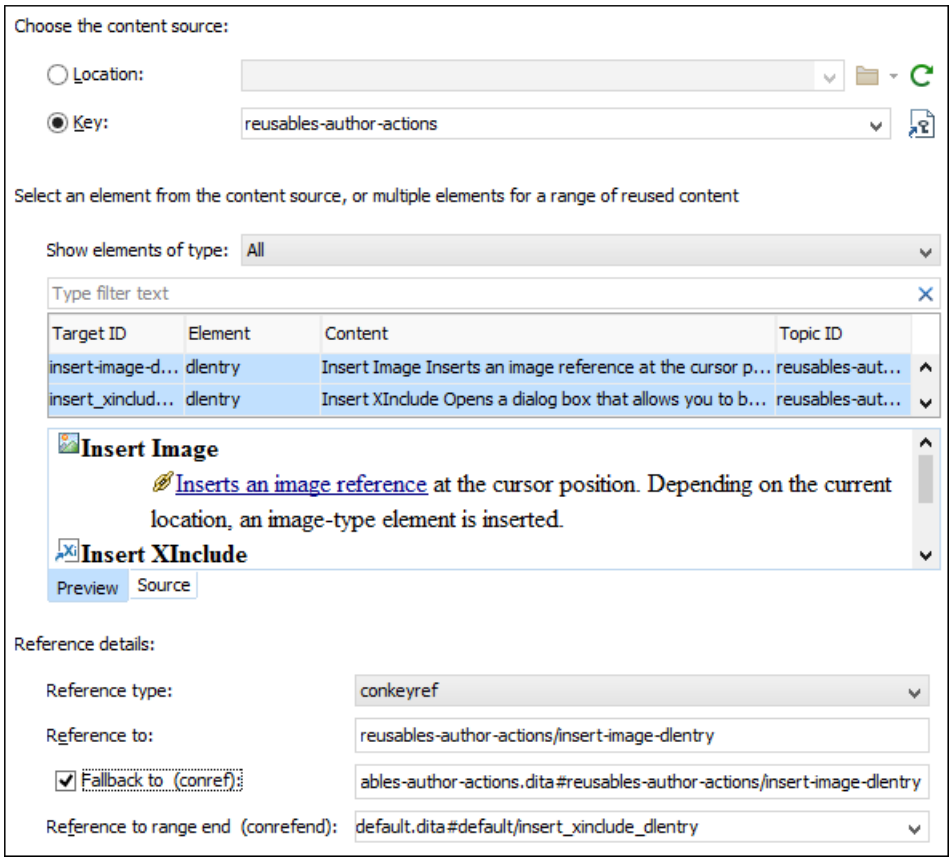

Figure 877: Insert Content Key Reference Options

Choose the content source Section

When **Key** is selected for the content source, you can use keys to reference content. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that allows you to select one from a list of all the keys that are gathered from the *root map* (you can also select one from the drop-down list in the **Key** field).

Note: If the current *DITA map* is not selected as the *root map*, no keys will be listed.

Tip: You can also use the ***DITA Reusable Components*** *view* for similar purposes.

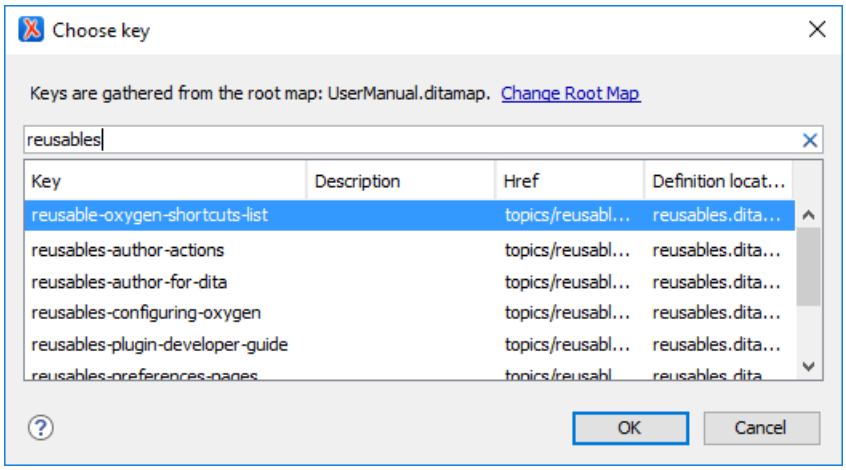

Figure 878: Choose Key Dialog Box

The **Choose Key** dialog box includes the following:

- **Change Root Map** - Opens a small dialog box that allows you to *select a root map*.
- **Search Filter** - You can enter text in the filter field at the top of the dialog box to filter the list and search for a specific keys.
- **Sortable Columns** - The dialog box includes the following columns that can be sorted by clicking on the heading:
  - **Key** - The name of the key.
  - **Description** - The description of the key that is obtained from the definition of the key (for example, the description for a *keydef* would be found in the `keyword` element inside *topicmeta*, or the description for a *topicref* would be found in a `navitle` element). For more information about where the data in this column is collected, see *this note*.
  - **Href** - The value of the *href* where the key points to.
  - **Definition Location** - The name of the *DITA map* where the key is defined.
- **Group by Definition Location** - A contextual menu action that can be used to group (and sort) all the keys based upon the value in the **Definition Location** column.

To insert a *content key reference* (`conkeyref`), select the key that contains the content you want to reference. Notice that the file path is shown in the **Href** column. Keys that do not have a value in the **Href** column are for referencing metadata with a `keyref` attribute. Therefore, to insert a `conkeyref`, you need to select a key that does have a value (file path) in the **Href** column.

After you select a key, click **OK** to return to the **Reuse Content** dialog box.

When a key that is defined as a *content key reference* has been selected, the **Reuse Content** dialog box offers the following additional options for inserting a `conkeyref`:

Select an element from the content source Section

Show elements of type

You can use this drop-down list to select specific types of elements to be displayed in the subsequent table. This can help you narrow down the list of possible source elements that you can select.

Text Filter Field

You can also use the text filter field to narrow down the list of possible source elements to be displayed in the subsequent table.

Element Table

Presents all the element IDs defined in the source topic. Use this table to select the **Target ID** of the element that you want to reference. You can select multiple contiguous elements to reference a block of content.

Preview Pane

Displays the content that will be references. If you select multiple elements in the element table, the content from all the selected elements is displayed.

Source Pane

Displays the source code of the element to be referenced.

Reference details Section

Reference type

The type of reference that will be inserted. If you selected a key that references a DITA resource, you will notice that **conkeyref** value is automatically selected.

Reference to

Oxygen XML Editor automatically fills this text field with the value of the `conkeyref` attribute to be inserted. However, you can edit this value if need be.

Fallback to (conref)

You can select this option to define a `conref` attribute to be used as a fallback to determine the content reference relationship if the specified `conkeyref` cannot be resolved.

Reference to range end (conrefend)

If you select multiple elements (of the same type) in the element table, Oxygen XML Editor automatically fills this text field with the `id` value of the last element in your selection. This value will be inserted as a `conrefend` attribute, defining the end of the `conkeyref` range.

Key Reference to Metadata (`keyref`) Options Using the Reuse Content Dialog Box

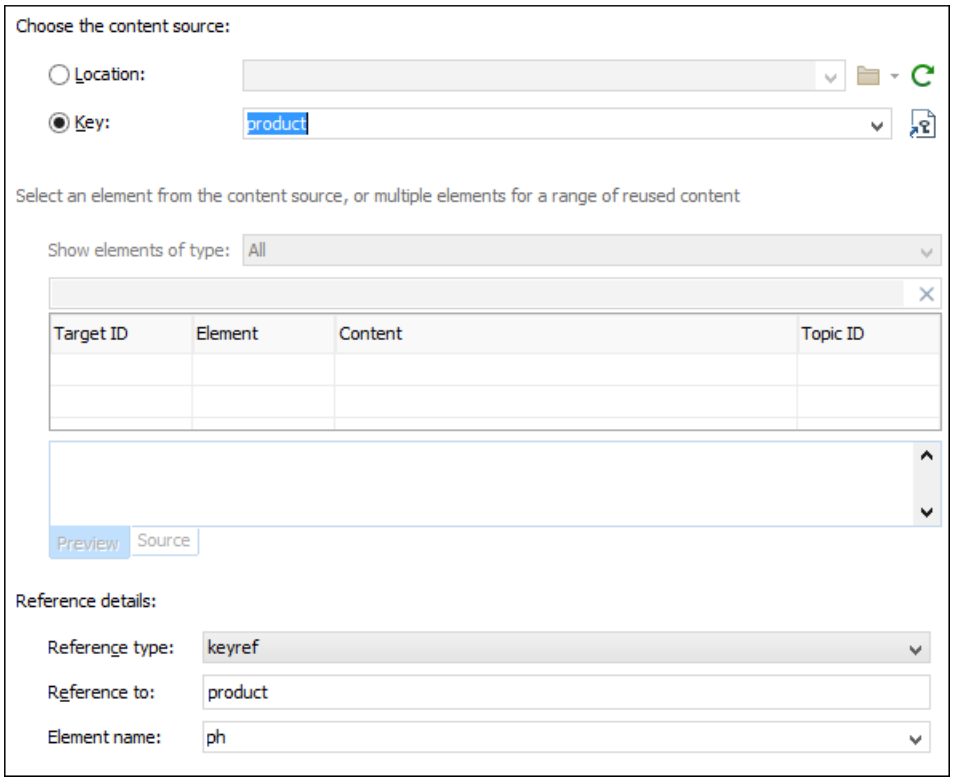

Figure 879: Insert Key Reference Options

Choose the content source Section

When **Key** is selected for the content source, you can use keys to reference content. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that allows you to select one from a list of all the keys that are gathered from the *root map* (you can also select one from the drop-down list in the **Key** field).

Note: If the current *DITA map* is not selected as the *root map*, no keys will be listed.

Tip: You can also use the ***DITA Reusable Components*** *view* for similar purposes.

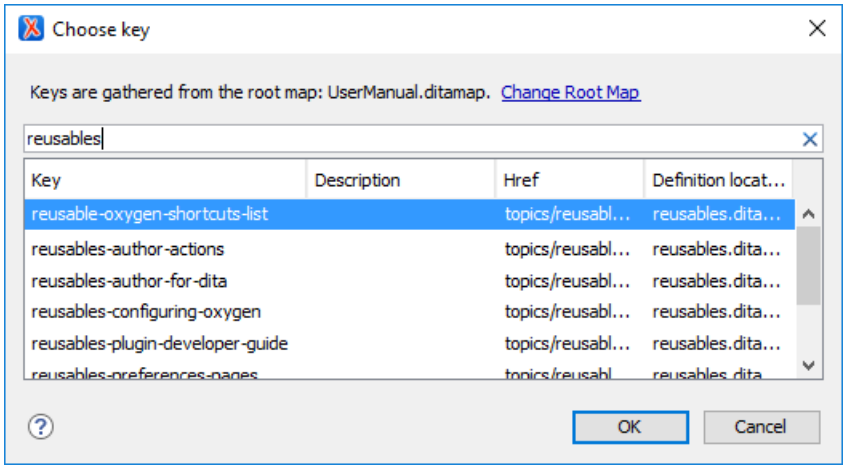

Figure 880: Choose Key Dialog Box

The **Choose Key** dialog box includes the following:

- **Change Root Map** - Opens a small dialog box that allows you to *select a root map*.
- **Search Filter** - You can enter text in the filter field at the top of the dialog box to filter the list and search for a specific keys.
- **Sortable Columns** - The dialog box includes the following columns that can be sorted by clicking on the heading:
  - **Key** - The name of the key.
  - **Description** - The description of the key that is obtained from the definition of the key (for example, the description for a *keydef* would be found in the `keyword` element inside *topicmeta*, or the description for a *topicref* would be found in a `navitle` element). For more information about where the data in this column is collected, see *this note*.
  - **Href** - The value of the *href* where the key points to.
  - **Definition Location** - The name of the *DITA map* where the key is defined.
- **Group by Definition Location** - A contextual menu action that can be used to group (and sort) all the keys based upon the value in the **Definition Location** column.

To insert a *key reference* to metadata (`keyref`), select the key you want to reference. Keys that do not have a value in the **Href** column are for referencing metadata with a `keyref` attribute. Therefore, to insert a `keyref`, you need to select a key that does not have a value (file path) in the **Href** column.

After you select a key, click **OK** to return to the **Reuse Content** dialog box.

When a key that references metadata has been selected, the **Reuse Content** dialog box offers the following additional options for inserting a `keyref`:

Select an element from the content source Section

This section is not used when referencing metadata.

Reference details Section

Reference type

The type of reference that will be inserted. If you selected a key that does not reference a DITA resource, you will notice that **keyref** value is automatically selected.

Reference to

Oxygen XML Editor automatically fills this text field with the value of the `keyref` attribute to be inserted.

Element name

Oxygen XML Editor automatically selects the element that is most commonly used for the selected type of key reference, but you can use the drop-down list to choose another element to use for the reference.

Finalizing Your Content Reference Configuration

Once you click **Insert** or **Insert and close**, the configured content reference is inserted into your document.

Tip: You can easily insert multiple content references by keeping the **Reuse Content** dialog box opened, using the **Insert** button.

Working with Code References

Code References

The DITA `coderef` element can be used to reference an external file that contains literal code. This is especially useful if you need to reference code from an external source that may occasionally change. Another advantage is that you don't have to convert illegal characters into their character equivalents. When the `coderef` is processed, the referenced code file is imported and delimiting characters (such as < or &) are displayed as standard text, rather than treated as XML markup.

For more information about code references, see *DITA 1.3 Specification: Coderef*.

Example of using a Coderef

```
<p>This code is an example of how to use a coderef.</p>
  <codeblock><coderef href="MyExternalCode.xsl"/></codeblock>
```

Defining Line Ranges

DITA-OT provides additional code reference processing support that allows you to define line ranges in case you only want to reference certain parts of the external file, rather than the whole file.

For information and examples of how to define line ranges, see *DITA Open Toolkit Documentation: Extended Code Reference Processing*.

Working with the Conref Push Mechanism

Content Reference Push Mechanism

The usual method of using content references pulls element content from a source element and inserts it in the current topic. DITA 1.2 introduced an alternative method of content referencing, allowing element content to be pushed, or injected, from a source topic to another topic without any special coding in the topic where the content will be re-used. This technique is known as a content reference *push* mechanism (*conref push*).

The *conref push* mechanism requires elements in the target topic (the topic where the content is to be pushed) to have ID elements, as the push mechanism inserts elements *before* or *after* a named element, or *replaces* the named element. Assuming the source topic is included in the *DITA map*, the *conref push* will be processed during publishing stage for the *DITA map*.

Example of a Conref Push Scenario

An example of a scenario in which a *conref push* would be useful is where a car manufacturer produces driver manuals that are distributed to various regions with their own specific regulations and certain sections need to be customized by the local car dealers before publishing. The local dealer could use a *conref push* technique to insert specific content without modifying the manufacturer-supplied content.

Push Current Element Action

Oxygen XML Editor includes an action that allows you to easily reference content with a *conref push* mechanism. The **Push Current Element** action is available in the **DITA** menu and in the **Reuse** subfolder of the contextual menu when editing in **Author** mode. Selecting this action opens the **Push current element** dialog box that allows you to select a target resource and element, and where to insert the current element content.

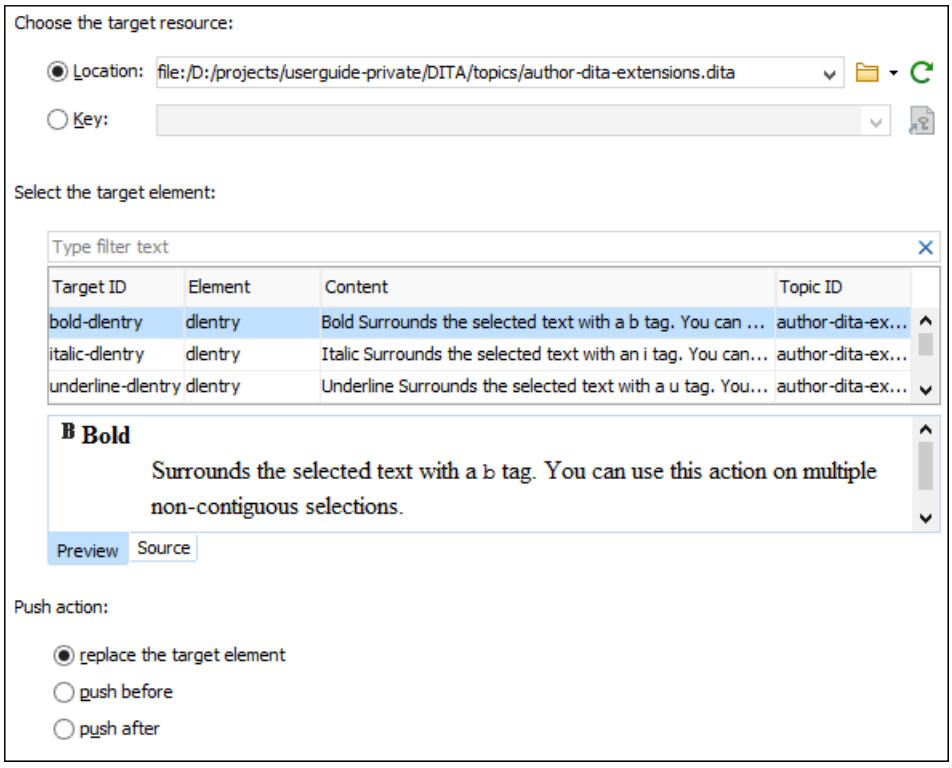

Figure 881: Push Current Element Dialog Box

This dialog box allows you to configure the following options for the *conref push* action:

Choose the target resource

Allows you to select a **Location** URL or a **Key** for the target resource and the table in the next section of the dialog box will be populated using the information from the specified resource.

Select the target element

The table in this section contains the available elements (identified by their ID) that belong to the same class as the current element on which the action was invoked.

Push action

Allows you to choose one of the following options for where you want to insert the current element content:

replace the target element

The target element will be replaced with the current element content.

On the technical side, the value of the `conaction` attribute in the current element will be set to `pushreplace` and the `conref` or `conkeyref` attribute will be set to the specified reference.

push before

The current element content will be inserted before the specified target element in the target resource.

On the technical side, the value of the `conaction` attribute in the current element will be set to `pushbefore`. Another element with the same name and class as the target element will be inserted in the document after the current element. The new element will have the `conaction` attribute set to `mark` and the `conref` or `conkeyref` attribute will be set to the specified reference.

push after

The current element content will be inserted after the specified target element in the target resource.

On the technical side, the value of the `conaction` attribute in the current element will be set to `pushafter`. Another element with the same name and class as the target element will be inserted in the document before the current element. The new element will have the `conaction` attribute set to `mark` and the `conref` or `conkeyref` attribute will be set to the specified reference.

You can also use the **Preview** panel to view the content that will be pushed and the **Source** panel to see the XML code for the content to be pushed. After you click **OK**, the *conref push* mechanism is inserted in the current document. The changes in the target resource will be processed when you transform the *DITA map*.

Related Information:

For more technical details about the conref push mechanism, refer to "The Conref Push Technique" section of The DITA Style Guide Best Practices for Authors.

Working with Reusable Components

In DITA, the content of almost any element can be made reusable simply by adding an `id` attribute to the element. The DITA content reference mechanism can reuse any element with an *ID*. However, it is not considered best practice to arbitrarily reuse pieces of text from random topics due to the difficulties this creates in trying to manage it. It also creates the possibility of authors deleting or changing content that is reused in other topics without being aware that the content is reused.

To prevent these types of problems, you can create reusable components to manage a separate set of topics that contain topics designed specifically for reuse. Then, all of your reusable content can be referenced from the reusable components and if the content needs to be updated you only need to edit it in one place.

Oxygen XML Editor allows you to select content in a topic, create a reusable component from it and reference that component in other locations by using the **Create Reusable Component** and **Insert Reusable Component** actions.

Related Information:

DITA Reusable Components View on page 1876

Creating a Reusable Content Component

Oxygen XML Editor makes it easy to create reusable content components from existing topic content.

Note: To ensure that the topic file that contains the reusable component is a valid container for just the reusable content component, without having to include the other elements required by a standard topic type, Oxygen XML Editor creates a specialized topic type on the fly. This specialization is designed to make sure that the content is compatible with the topic type from which it is created.

Follow these steps to create a reusable component:

1. In **Author** mode, select the content you want to make into a reusable component.
2. Select the **Create Reusable Component** action that is available in the **DITA** menu or the **Reuse** submenu of the contextual menu.
   The **Create Reusable Component** dialog box is displayed.
3. Use the **Reuse Content** drop-down list to select the scope of the content to be made reusable. It allows you to select how much of the current content you want to make reusable. The choices presented include the element at the current cursor position and its ancestor elements.
4. Add a description. This becomes the title of the topic that contains the reusable component, but is not part of the reusable content. It is just to help you identify the reusable content and will not become part of your output.
5. If you want to replace the extracted content with a reference to the new component you should leave the **Replace selection with content reference** option selected. This is recommended, since the point of reuse is to maintain only one copy of the content.
6. Select a file name and location to save the topic containing the reusable component and click **Save**. It is considered best practice to save or store reusable components in an area set aside for that purpose.
   If the **Replace selection with content reference** option was selected, Oxygen XML Editor replaces the current content with a `conref` attribute. The content of the content reference will be displayed in your current topic with a gray background, but it will no longer be editable since it is stored in a separate file. To edit the source of the reusable component, click the **Edit Content** icon at the beginning of the inserted content.

You now have a reusable component that you can include in other topics by using the **Insert Reusable Component** action that is available in the **DITA** menu or the **Reuse** submenu of the contextual menu. You can also reference this new reusable component by using a *content reference* or *content key reference*.

Inserting a Reusable Content Component

Oxygen XML Editor includes an **Insert Reusable Content** action that allows you to easily insert a reusable content component that you *created using the **Create Reusable Component** action*.

CAUTION: This action is only designed to insert reusable components created using the Oxygen XML Editor **Create Reusable Component** action. It assumes certain things about the structure of the reusable content file that may not be true of reusable content created by other methods and it may not provide the expected results if used with content that does not have the same structure.

The **Insert Reusable Content** action creates a DITA `conref` to insert the content, and creates a parent element for the `conref` attribute based on the type of the reusable element in the reusable component file. This action ensures that the correct element is used to create the `conref`. However, that element must still be inserted at a point in the current topic where that element type is permitted.

To insert a reusable component that was created using the **Create Reusable Component** action, follow these steps:

1. Place the cursor at the insertion point where you want the reusable component to be inserted.
2. Select the **Insert Reusable Component** action that is available in the **DITA** menu or the **Reuse** submenu of the contextual menu.
   The **Insert Reusable Component** dialog box is displayed.
3. Locate the reusable content file in which you want to insert its content.
4. If you select **Content reference** in the **Insert as** drop-down list, the action will add a `conref` attribute to the DITA element at the current location. If you select **Copy** in the drop-down list, the content of the reusable component file will simply be pasted at the current location (assuming the content is valid at the current location).
5. Click **Insert** to perform the action.

Working with Variable Text in DITA

You may often find that you want a certain piece of text in a topic to have a different value in various circumstances. For example, if you are reusing a topic about a feature that is shared between several products, you might want to make the name of the product variable so that the correct product name is used in the manual for each product.

For example, you might have a sentence like this:

```
The quick-heat feature allows [product-name] to come up to temperature quickly.
```

You need a way to substitute the correct product name for each product.

One way to do this would be to use conditional profiling, as in the following example:

```
<p>The quick-heat feature allows
    <ph product="basic">Basic Widget</ph>
    <ph product="pro">Pro Widget</ph>
to come up to temperature quickly.</p>
```

Creating Variable Text Using Keys

In DITA, you can create variable text using *keys*.

One way to do this would be to provide conditional values using the `product` profiling attribute.

However, this approach means that you are repeating the product names over and over again everywhere the product name is mentioned. This is time consuming for authors and will create a maintenance problem if the product names change.

Creating Variable Content Using a Key Reference

The alternative is to use a key reference, as in the following example:

```
<p>The quick-heat feature allows <ph keyref="product"/>
   to come up to temperature quickly.</p>
```

The definition of the key reference determines the name of the product:

```
<keydef keys="product" product="basic">
    <topicmeta>
      <keywords>
        <keyword>Basic Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
  <keydef keys="product" product="pro">
    <topicmeta>
      <keywords>
        <keyword>Pro Widget</keyword>
      </keywords>
    </topicmeta>
  </keydef>
```

When the content is published, the current value of the key `product` will be inserted.

Inserting a Keyref

To insert a key reference into a document in Oxygen XML Editor **Author** mode, use one of the following methods:

- **DITA Reusable Components View Method**

  Use the ***DITA Reusable Components*** *view* to insert a *variable reference* to the *defined key*.
- **Code Template Method**

  Add the source code pattern of the *defined key* to a *code template* so that it appears in the list of proposals in the *Content Completion Assistant*.
- **Edit Attributes Method**

  Manually insert the `keyref` attribute using the attributes editor as follows:

  1. Press **Enter** and select any DITA element that supports the `keyref` attribute.
  2. Select **Edit Attributes** from the contextual menu (or simply press **Alt+Enter**) to bring up the *attributes editor*.
  3. In the **Name** field, select `keyref`.
  4. In the **Value** field, select or enter the name of the *defined key*.
- **Text Mode Method**

  If you are using ***Text*** *mode*, when you insert a `keyref` attribute, after you enter the first quote (`keyref="`), the **Content Completion Assistant** will list all the defined keys that you can select from. Note that this only works for local files.

Defining Keys in DITA Maps on page 1804

Working with DITA 1.3 Key Scopes

DITA 1.3 includes the possibility of using a concept called *Key Scopes* (or scoped keys). It allows you to reuse a topic in multiple places within the same *DITA map*, but with slightly different content in each instance.

Key Scopes Use-Case

Suppose that you develop a software product and you have a topic in your user guide that explains how to install your product on a Windows operating system. Suppose that the steps are exactly the same for installing it on Linux and the only difference is the name of the operating system. Therefore, it would be helpful if you could reuse the exact same content in two different topics, but with the name of the operating system different in each instance. In DITA 1.2, this is not possible since keys can only be resolved to a single value. However, with the DITA 1.3 *Key Scopes* mechanism, you can define multiple values for the same key depending on the context.

How to Use Key Scopes in Oxygen XML Editor

To use DITA 1.3 key scopes in Oxygen XML Editor, follow these steps:

1. *Define the keys* to be used in multiple places within your *DITA map*.

2. For each particular topic that contains the keys, define the key scopes:
   a. Right-click the topic in the ***DITA Maps Manager*** and select **Edit properties**.
   b. In the ***Keys*** *tab*, enter a value (or multiple values) in the **Key scopes** field.

      Tip: If you do not see the **Key scopes** field, make sure the support for DITA 1.3 (DITA-OT 2.x) is enabled in the *DITA preferences page*.
   c. Click **OK** to save your changes.
3. Save the *DITA map*.

   Result: In the ***DITA Maps Manager***, you can now see the key scopes in brackets and when you open each topic reference.

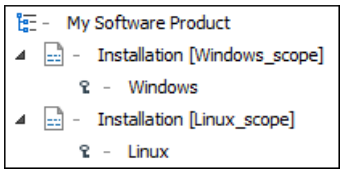

Figure 882: Key Scopes in DITA Maps Manager

The content will also be expanded in **Author** mode according to the context of the key scope you defined for that particular topic. Also, when you transform the *DITA map*, the scoped keys will be reflected in the published content.

Resources

- You can find a more detailed example and download samples for reuse possibilities based on key scopes in the *DITA 1.3 Key Scopes - Next Generation of Reuse* blog post.
- You can also watch our *DITA 1.3 video tutorial* to see how key scopes can be used in Oxygen XML Editor.

Working with DITA 1.3 Branch Filtering on page 1875

Oxygen XML Blog: DITA 1.3 Key Scopes - Next Generation of Reuse

Oxygen Video Tutorial: DITA 1.3 (Key Scopes, Branch Filtering)

Working with DITA 1.3 Branch Filtering

DITA 1.3 allows you to use a mechanism called *Branch Filtering* that enables you to set filtering conditions for specific branches of a *DITA map*. This makes it possible for multiple conditional profiles to be applied within a single publication, each time with a different filter.

Branch Filtering Use-Case

Suppose that you sell two models of a mobile phone and you need to create a brochure for each model. You want both brochures to have the same structure and most of the content is the same for both brochures. The only differences are in the values for certain details (for example, the model name, size dimensions, battery life, etc.) Therefore, it would be helpful if you could use the same topic and reference it twice in the same map, with each reference using different filtering conditions. In DITA 1.2, this is not possible since you can only apply one DITAVAL filter to a map. However, with the DITA 1.3 *Branch Filtering* mechanism, you can reuse content multiple times within the same map, each time using different filters.

How to Use Branch Filtering in Oxygen XML Editor

To use DITA 1.3 branch filtering in Oxygen XML Editor, follow these steps:

1. The support for DITA 1.3 must be enabled in the *DITA preferences page*.
2. Assuming you have already *defined your profiling attributes*, *create a DITAVAL filter file*.
3. Insert a reference to the DITAVAL filter file in the *DITA map*:
   a. Right-click the *DITA map* reference in the ***DITA Maps Manager*** and select **Append Child** > **DITAVAL Reference**.

Tip: If you do not see the **DITAVAL Reference** option, make sure the support for DITA 1.3 (DITA-OT 2.x) is enabled in the *DITA preferences page*.

b. Select the DITAVAL file.

c. Click **Insert and Close**.

4. Save the *DITA map*.

Result: You can now see the **ditaval** files referenced in the ***DITA Maps Manager*** and when you transform the *DITA map*, filtered content will be reflected in the published output.

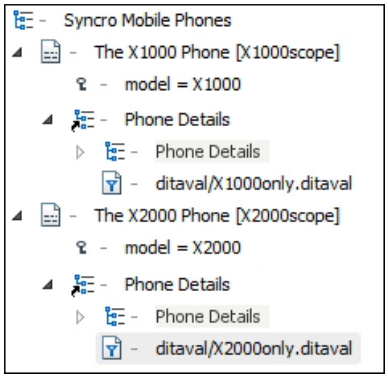

Figure 883: Branch Filtering in DITA Maps Manager

Resources

- You can find a more detailed example and download samples for reuse possibilities based on key scopes in the *DITA 1.3 Branch Filtering - Next Generation of Reuse* blog post.
- You can also watch our *DITA 1.3 video tutorial* to see how branch filtering can be used in Oxygen XML Editor.

Oxygen XML Blog: DITA 1.3 Branch Filtering - Next Generation of Reuse

Oxygen Video Tutorial: DITA 1.3 (Key Scopes, Branch Filtering)

DITA Reusable Components View

The **DITA Reusable Components** view is helpful if you use a large amount of keys or reusable components in your DITA project. It collects all of the keys and reusable components that are defined in the *root map* and presents them in a dynamic table where you can easily locate and insert references to them. If the view is not displayed, it can be opened by selecting it from **Window** > **Show View**. It will appear in the bottom-right section of the editor. It re-collects the keys anytime the *root map is changed* or you switch the editor focus to a different file.

It includes two tabs:

- ***Keys*** - Displays all the *keys* that are defined in the *root map* and provides ways to easily insert references to them as cross reference links, key references, or variables. It includes a search filter field to help you find particular keys, it has several sorting options, and some contextual menu actions. It also supports drag and drop actions and double-clicking a key is the fastest way to insert a reference.
- ***Components*** - Displays all the topics (from the *root map*) that contain *reusable components* and provides ways to easily insert them as content references or content key references. To determine which topics to display in this tab, Oxygen XML Editor looks for any *topicref* in the *root map* that is marked as *resource-only*. This tab includes a search field, some filtering options, and some simple links and contextual menu actions to quickly insert references or open their source file. It also supports drag and drop and double-clicking actions.

Keys Tab

The **DITA Reusable Components** view collects all the *keys* that are defined in the current *root map* and displays them in the **Keys** tab. Keys that are defined with a value have that value listed in the **Description** column while keys that are defined with an *href* pointing to their location have that href value listed in the **Href** column.

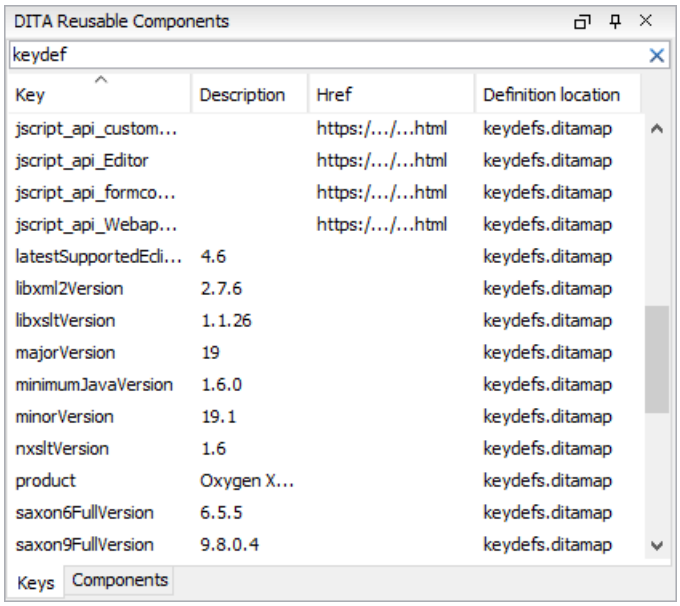

Figure 884: DITA Reusable Components View - Keys Tab

The **Keys** tab includes the following features and options:

Search Filter

You can enter text in the filter field at the top of this tab to filter the list and search for a specific keys.

Sortable Columns

This tab includes the following columns that can be sorted by clicking on the heading:

- **Key** - The name of the key.
- **Description** - The description of the key that is obtained from the definition of the key (for example, the description for a *keydef* would be found in the `keyword` element inside *topicmeta*, or the description for a *topicref* would be found in a `navitle` element). For more information about where the data in this column is collected, see *this note*.
- **Href** - The value of the *href* where the key points to.
- **Definition Location** - The name of the *DITA map* where the key is defined.

Note: The **Description** column collects data from the definition of the key, either from the `navtitle` element or, if missing, from the `keyword` element. The following example shows two key definitions that will be collected in the keys table. Their corresponding information from the **Description** column will display `oxygen.sh` and `oxygen.tar.gz` respectively.

```
<keydef keys="executableInstallLinux">
  <topicmeta>
    <keywords>
      <keyword>oxygen.sh</keyword>
    </keywords>
  </topicmeta>
</keydef>

<keydef keys="archiveInstallAll">
  <topicmeta>
    <navtitle>
      oxygen.tar.gz
    </navtitle>
  </topicmeta>
</keydef>
```

Double-Click Mechanism

You can double-click any key listed in this tab to insert a key reference at the current cursor position or surrounding the current selection.

- If the selected key points to an `href` value, it is inserted as a *cross reference link (xref)*.
- If the selected key is a reference to an image, it is inserted as an `image` element.
- If the selected key does not have an associated `href`, it is inserted as a *variable reference (ph)*.

Drag and Drop Mechanism

You can drag a key from this tab and drop it in the main editor to insert a key reference at the current cursor position.

- If the selected key points to an `href` value, it is inserted as a *cross reference link (xref)*.
- If the selected key is a reference to an image, it is inserted as an `image` element.
- If the selected key does not have an associated `href`, it is inserted as a *variable reference (ph)*.

Contextual Menu Actions

Insert as Link

Inserts a *cross reference link (xref)* to the selected key at the current cursor position or surrounding the current selection.

Insert as Variable

Inserts a *variable reference (ph)* to the selected key at the current cursor position or surrounding the current selection. However, if the selected key is a reference to an image, this action inserts the key reference in an `image` element.

Insert as Keyref

Presents a submenu with all the elements that can be inserted at the current cursor position. Selecting an element will insert that element at the current cursor position or surrounding the current selection with a `keyref` attribute and its value set to the selected key.

Go to Definition

Opens the *DITA map* where the key is defined.

Group by Definition Location

A toggle action that can be used to group (and sort) all the keys based upon the value in the **Definition Location** column.

Components Tab

The **DITA Reusable Components** view collects all the topics from the current *root map* that are marked as *resource-only*, then collects the reusable components from those topics, and displays them in the **Components** tab. To set a topic as *resource-only*, the `topicref` in the DITA map file needs to have a `processing-role` attribute set like this:

```
<topicref href="topics/randomize-xml-content.dita" processing-role="resource-only"/>
```

The **DITA Reusable Components** view considers topic references that contain `processing-role="resource-only"` to be candidates to contain reusable components. The reusable components inside these topics are collected from all elements that have an *ID* specified. These reusable components are displayed in the **Components** tab along with the file name and the specific names of the elements that contain an *ID* attribute.

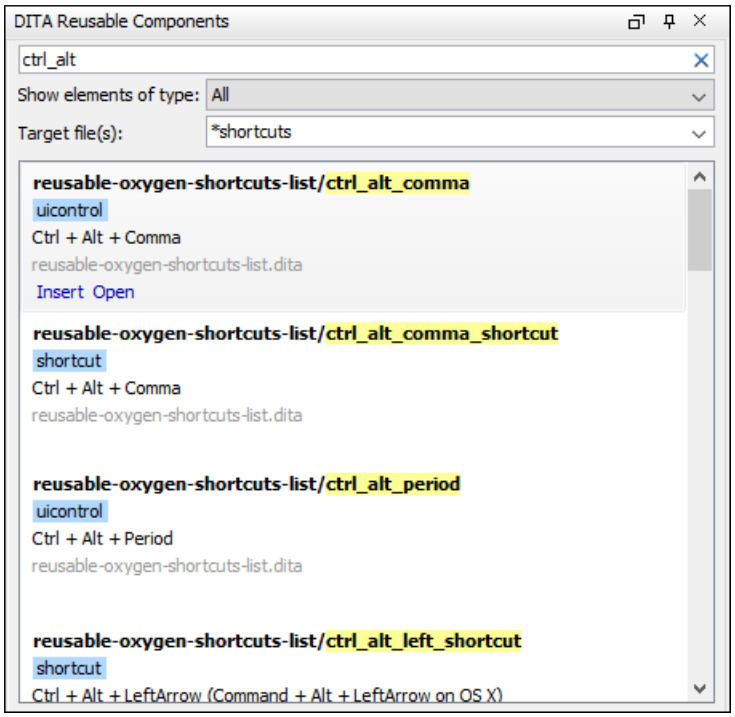

Figure 885: DITA Reusable Components View - Components Tab

The **Components** tab includes the following features and options:

Search Filter

You can enter text in the filter field at the top of this tab to filter the list and search for specific content inside the list of reusable components. This field supports many of the *Lucene-based search patterns*, such as wildcards (*, ?), boolean operators (AND, OR, NOT), fuzzy searches (~), boosting searches (^), and more.

Show Elements of Type

You can use this drop-down list to select specific types of elements to be displayed in the subsequent preview window. This can help you narrow down the list of possible source elements that you can select.

Target File(s)

You can use this combo box to search for specific target files (the topics that contain reusable components) or select a file from its drop-down list. You can also use wildcards (such as * or ?) in this field.

Double-Click Mechanism

You can double-click any reusable component listed in preview window in this tab to insert it as a content reference or content key reference at the current cursor position or replace the current selection.

- If the parent topic of the selected component has a key defined, it is inserted as a *content key reference (conkeyref)*.
- If the parent topic of the selected component does not have a key defined, it is inserted as a *content reference (conref)*.

Drag and Drop Mechanism

You can drag a reusable component from the preview window in this tab and drop it in the main editor to insert a content reference or content key reference at the current cursor position.

- If the parent topic of the selected component has a key defined, it is inserted as a *content key reference (conkeyref)*.
- If the parent topic of the selected component does not have a key defined, it is inserted as a *content reference (conref)*.

Hover and Click Actions

If you hover over a component shown in the preview window, you have access to the following link actions:

Insert

Inserts the component as a content reference or content key reference at the current cursor position or replaces the current selection. If the parent topic has a key defined, it is inserted as a *content key reference (conkeyref)*. Otherwise, it is inserted as a *content reference (conref)*.

Open

Opens the source file that contains the reusable component.

Contextual Menu Actions

Insert Content Reference

Inserts the component as a *content reference (conref)* at the current cursor position or replaces the current selection.

Insert Content Key Reference

Inserts the component as a *content key reference (conkeyref)* at the current cursor position or replaces the current selection. This action is only available if the parent topic has a key defined.

Go to Definition

Opens the source file that contains the reusable component.

Linking in DITA

DITA provides support for various types of linking between topics, some of which is automated, while others are specified by the author. Oxygen XML Editor provides support for all forms of linking in DITA.

Linking Between Parent, Child, and Sibling Topics

A *DITA map* creates a hierarchical relationship between topics. That relationship map expresses a narrative flow from one topic to another, or it may be used as a classification system to help the reader find topics based on their classification, without creating a narrative flow. Since there may be various types of relationships between topics in a hierarchy, you may want to create links between topics in a variety of ways. For instance, if your topics are supposed to be organized into a narrative flow, you may want to have links to the next and previous topics in that flow. If your topics are part of a hierarchical classification, you may want links from parent to child topics, and vice versa, but not to the next and previous topics.

Parent, child, and sibling links are created automatically by the DITA output transformations (and may differ between various output formats). The kinds of links that are created are determined by the DITA *collection-type attribute*.

In-Line Linking in the Content of a Topic

DITA supports linking within the text of a topic using the `xref` element. The destination of the link can be expressed directly using the `href` attribute or indirectly using the `keyref` attribute. If you use the `keyref` attribute, you link to a key rather than directly to a topic. That key is then assigned to a topic in a map that includes that topic. This means that you can change the destination that a key points to by editing the key definition in the map or by substituting another map in the build.

Linking Between Related Topics

In addition to the relationships between topics that expressed by their place in the hierarchy of a map, a topic may be related to other topics in various ways. For instance, a task topic may be related to a concept topic that gives

the background of the task, or to a reference topic that provides data needed to complete the task. Task topics may also be related to other tasks in a related area, or concepts to related concepts.

Typically, they are grouped in a list at the end of the topic, although this depends on the behavior of the output transformation. DITA provides two mechanisms for expressing relationships between topics at the topic level: the **Related Links** section of a topic and relationship tables in maps.

Managing Links

Links can break for a variety of reasons. The topic that a link points to may be renamed or removed. A topic may be used in a map that does not include a linked topic. A topic or a key may not exist in a map when a particular profile is applied. The ***DITA Maps Manager*** provides a way to *validate all the links in the documents that are included in the map*. This can include validating all the profiling conditions that are applied.

Hierarchical Linking in DITA Maps

To create hierarchical linking between the topics in a *DITA map*, you set the appropriate value of the `collection-type` attribute on the map. See the *DITA documentation* for the meaning of each of the values of the `collection-type` attribute.

Note: Publishing scripts determine when and how to create hierarchical links. The `collection-type` attribute does not force a particular style of linking. Instead, it declares what the nature of the relationship is between the topics. The publishing scripts use that information to determine how to link topics. Scripts for different types of media might make the determination depending on what is appropriate for the particular type of media. You can provide additional instructions to the scripts using the `linking` attribute.

To add the `collection-type` to an item in a map:

1. Right-click the topic and choose **Edit Properties**. The **Edit Properties** dialog box is displayed.
2. In the **Attributes** tab, select the appropriate value from the **Collection type** drop-down list.
3. You can use the **Other attributes** table to add a value to the `linking` attribute.

Linking in DITA Topics

Direct Links

You can create inline links in the content of a DITA topic using the `xref` element. The destination of the link can be expressed directly by using the `href` attribute and the target can be another topic or a specific element within the other topic, another location within the same topic, a file, or a web link. You can also create direct *related links* to topics, files, or websites in a DITA topic using the `related-links` element.

Indirect Links Using Keys

The destination of the link can also be expressed indirectly by using *keys* to create either inline links or *related links* (with the `keyref` attribute). By using keys, you avoid creating a direct dependency between topics. This makes links easier to manage and can make it easier to reuse topics in various publications. It can also be helpful in verifying the completeness of a publication, by ensuring that a publication map provides a key definition for every key reference used in the content.

Links based on keys require two pieces:

- Key Definition - Assigns a key to a topic so that other topics can link to it. For more information, see *Defining Keys in DITA Maps* on page 1804.
- Key Reference - Created in an `xref` element and specifies the key to link to.

The key reference points to a key definition, and the key definition points to a topic. Key definitions are created in maps, as an element on the `topicref` element that points to a topic. This allows you to assign a particular key to one topic in one map and to another topic in another map. When a topic that links to that key is used in each of these maps, the links work correctly in both maps.

Inserting a Link in Oxygen XML Editor

To insert a link in ***Author*** *mode*, use the actions available in the **Link** drop-down menu from the toolbar (or the **Link** submenu in the contextual menu or **DITA** menu). You can choose between the following types of inline links:

Cross Reference

Opens the ***Cross Reference (xref)*** *dialog box* that allows you to insert a cross reference link to a target resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your DITA map structure. Once the target resource has been selected, you can also target specific elements within that resource. Depending on the context where it is invoked, the action inserts one of the following two elements:

- `xref` - Used to link to other topics or another location within the same topic and points to the target using the `href` or `keyref` attribute.
- `fragref` - A logical reference to a fragment element within a syntax diagram and points to the target using the `href` or `keyref` attribute.

File Reference

Opens a dialog box that allows you to insert a link to a target file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. It inserts an `xref` element with either an `href` attribute or a `keyref` attribute. If you select **Location** for the target, the link is expressed in an `href` attribute. If you select **Key** for the target, keys will be used to express the link in a `keyref` attribute. You can select a key from the drop-down list or click the **Choose Key Reference** button to use the ***Choose Key*** *dialog box*.

Web Link

Opens a dialog box that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. It inserts an `xref` element with either an `href` attribute or a `keyref` attribute. If you select **URL** for the target resource, the link is expressed in an `href` attribute. If you select **Key** for the target, keys will be used to express the link in a `keyref` attribute. You can select a key from the drop-down list or click the **Choose Key Reference** button to use the ***Choose Key*** *dialog box*.

Related Link to Topic

Opens the ***Cross Reference (xref)*** *dialog box* that allows you to insert a link to a target resource in a related links section that is typically at the bottom of your topic (although this depends on the behavior of the output transformation). The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. Specifically, it inserts a `link` element inside a *related-links element*.

Related Link to File

Opens a dialog box that allows you to insert a link to a target file resource in a related links section that is typically at the bottom of your topic (although this depends on the behavior of the output transformation). The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. Specifically, it inserts a `link` element inside a *related-links element*. If you select **Location** for the target, the link is expressed in an `href` attribute. If you select **Key** for the target, keys will be used to express the link in a `keyref` attribute. You can select a key from the drop-down list or click the **Choose Key Reference** button to use the ***Choose Key*** *dialog box*.

Related Link to Web Page

Opens the **Web Link** dialog box that allows you to insert a link to a target web-related resource in a related links section that is typically at the bottom of your topic (although this depends on the behavior of the output transformation). The target resource can be a URL or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. Specifically, it inserts a `link` element inside a *related-links element*. If you select **URL** for the target resource, the link is expressed in an `href` attribute. If you select **Key** for the target, keys will be used to express the link in a `keyref` attribute. You can

select a key from the drop-down list or click the **Choose Key Reference** button to use the ***Choose Key*** *dialog box*.

Cross Reference (xref) Dialog Box

The **Cross Reference (xref)** dialog box is displayed when you insert a **Cross Reference** or **Related Link to Topic** (from the **Link** drop-down menu). It allows you to insert a link to a target resource at the current location within a document (for a **Cross Reference** link) or in a related links section (for a **Related Link to Topic**). The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource.

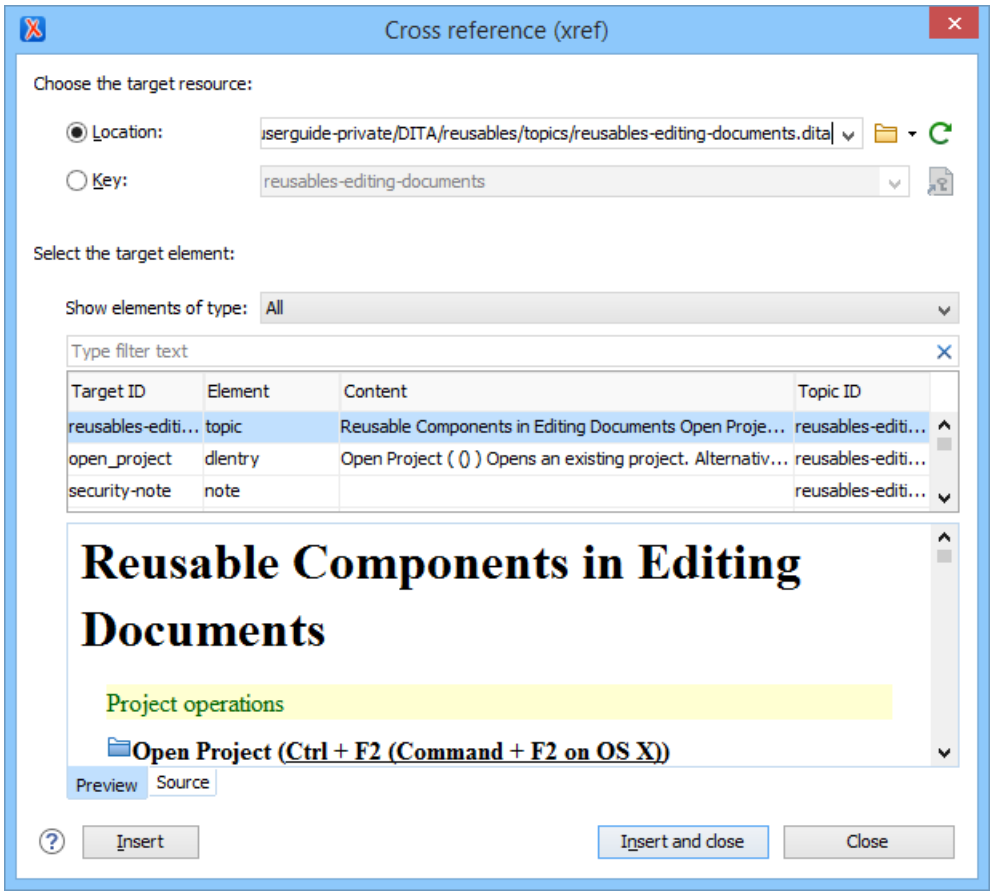

Figure 886: Cross Reference (xref) Dialog Box

This dialog box includes the following sections and fields:

Choose the Target Resource Section

Location

If you select **Location** for the target, the link is expressed in an `href` attribute.

Key

If you select **Key** for the target, keys will be used to express the link in a `keyref` attribute. You can use the **Choose Key Reference** button to open the **Choose Key** dialog box that allows you to select one from a list of all the keys that are gathered from the *root map* (you can also select one from the drop-down list in the **Key** field).

Tip: You can also use the ***DITA Reusable Components*** *view* for similar purposes.

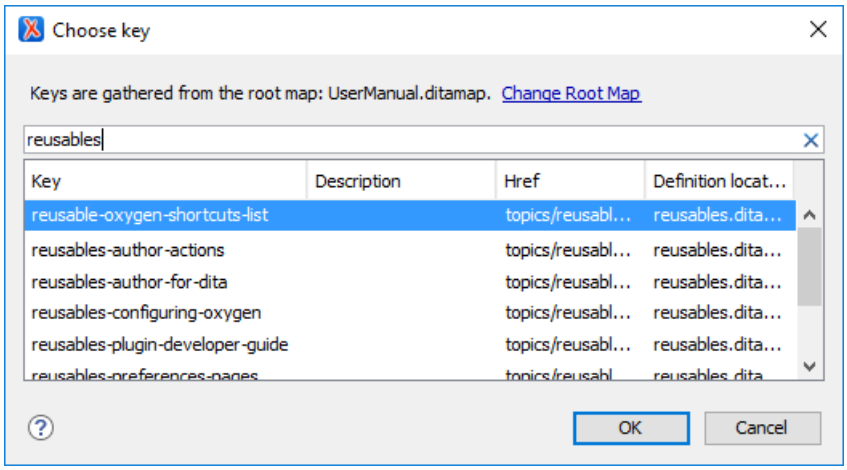

Figure 887: Choose Key Dialog Box

The **Choose Key** dialog box includes the following:

- **Change Root Map** - Opens a small dialog box that allows you to *select a root map*.
- **Search Filter** - You can enter text in the filter field at the top of the dialog box to filter the list and search for a specific keys.
- **Sortable Columns** - The dialog box includes the following columns that can be sorted by clicking on the heading:
  - **Key** - The name of the key.
  - **Description** - The description of the key that is obtained from the definition of the key (for example, the description for a *keydef* would be found in the `keyword` element inside *topicmeta*, or the description for a *topicref* would be found in a `navitle` element). For more information about where the data in this column is collected, see *this note*.
  - **Href** - The value of the *href* where the key points to.
  - **Definition Location** - The name of the *DITA map* where the key is defined.
- **Group by Definition Location** - A contextual menu action that can be used to group (and sort) all the keys based upon the value in the **Definition Location** column.

Select the Target Element Section

This section can be used to target a specific element inside the target resource.

Show elements of type

You can use this drop-down list to select specific types of elements to be displayed in the subsequent table. This can help you narrow down the list of possible source elements that you can select.

Text Filter Field

You can also use the text filter field to narrow down the list of possible source elements to be displayed in the subsequent table.

Element Table

Presents all the element IDs defined in the source topic. Use this table to select the **Target ID** of the element that you want to reference.

Preview Pane

Displays the content that will be references.

Source Pane

Displays the XML source code of the element to be referenced.

Once you click **Insert** or **Insert and close**, the configured cross reference is inserted into your document.

Tip: You can easily insert multiple cross references by keeping the dialog box opened, using the **Insert** button.

Using Copy/Paste Actions to Insert a Cross Reference

Oxygen XML Editor also includes support for inserting cross references with simple copy/paste actions. The copied content must be an entire DITA XML element with an ID attribute or a `topicref`. Also, the location in the document where you paste the link must be valid, although as long as the ***Smart paste and drag and drop*** *option* is selected in the **Schema Aware** preferences page, if you try to paste it in an invalid location, Oxygen XML Editor will attempt to place it in a valid location, and may prompt you with one or more choices for where to place it. You can paste the link as a cross reference with the link expressed in an `href` attribute or in a `keyref` attribute.

To insert a cross reference link (expressed in an `href` attribute) using copy/paste actions, follow these steps:

1. Copy an entire DITA element that has an ID attribute assigned to it or a `topicref`.
2. Place the cursor at a location, where you want to insert the link.
3. Select the **Paste as Link** action from the **Paste Special** submenu from the contextual menu.

To insert a cross reference link (expressed in a `keyref` attribute) using copy/paste actions, follow these steps:

1. In the ***DITA Maps Manager*** *view*, make sure that the ***Root map*** *combo box* points to the correct map that stores the keys.
2. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the ***DITA Maps Manager***, select **Edit Properties**, and enter a value in the **Keys** field.
3. Copy an entire DITA element that has an ID attribute assigned to it from a topic with an assigned key, or a `topicref` from a *DITA map*.
4. Place the cursor at a location, where you want to insert the link.
5. Select the **Paste as Link (keyref)** action from the **Paste Special** submenu from the contextual menu.

DITA Reusable Components View on page 1876

Linking with Relationship Tables in DITA

A relationship table is used to express relationships between topics outside of the topics themselves. The DITA publishing scripts can then create links between related topics when the content is published.

The reason for using a relationship table is to help make topics easier to reuse. If a topic links directly to another topic, this creates a dependency between the topics. If one topic is reused in a publication where the other is not used, the link is broken. By defining relationships between topics in a relationship table, you avoid creating this dependency.

To create an appropriate set of links between topics in multiple publications, you can create a separate relationship table for each publication. If you are creating multiple publications by applying profiling conditions to a single map, you can also profile your relationship table.

To create a relationship table, follow these steps :

1. If the map is currently open in the ***DITA Maps Manager***, double-click the map icon ( ) to open the map in **Author** mode. If it opens in **Text** mode, click **Author** at the bottom left to switch to **Author** mode.
2. Move the insertion point inside the *map* root element (usually `map`, but it might be `bookmap`, or another specialization of the `map` element). The easiest way to do this is to click below the title of the map in the editor and then press the up arrow once. Confirm that you are inside the *map* root element by checking the breadcrumbs at the top left of the editor window. You should only see the name of the *map* root element.
3. Select the **Insert Relationship Table** action on the toolbar or from the **Relationship Table** submenu of the contextual menu.
   The **Insert Relationship Table** dialog box is displayed.
4. Set the number of rows, the number of columns, a table title (optional), and select whether or not you want a table header. Click **Insert**.
5. Enter the type of the topics in the header of each column.

The header of the table (the `relheader` element) already contains a `relcolspec` element for each table column. You should set the value of the attribute `type` of each `relcolspec` element to a value such as *concept*, *task*, or *reference*. When you click in the header cell of a column (that is a `relcolspec` element), you can see all the attributes of that `relcolspec` element, including the `type` attribute in the ***Attributes** view*. You can edit the attribute type in this view.

6. To insert a topic reference in a cell, place the cursor in a table cell and select ***Insert Reference*** from the contextual menu or the **DITA Map** toolbar.
7. To add a new row to the table or remove an existing row use **Insert Relationship Row**/**Delete Relationship Row** from the contextual menu or the **DITA Map** toolbar.
8. To add a new column to the table or remove an existing column, use **Insert Relationship Column**/**Delete Relationship Column** contextual menu or the **DITA Map** toolbar. If you double-click the relationship table (or select it and press **Enter**, or choose **Open** from the contextual menu) the *DITA map* is opened in the editor with the cursor positioned inside the corresponding relationship table.
9. To add topic references to your relationship table, drag and drop topics from the ***DITA Maps Manager*** or the ***Project*** view into the appropriate cell in the relationship table.

   See the *DITA documentation* for a full explanation of the relationship table format and its options. Note that you can change all the selections that you make here later by using the actions on the toolbar (or in the **Relationship Table** submenu of the contextual menu) or by editing the underlying XML in **Text** mode.
10. Save the *DITA map*.
    Relationship tables are also displayed in the ***DITA Maps Manager** view*, along with the other elements in its *DITA map*.

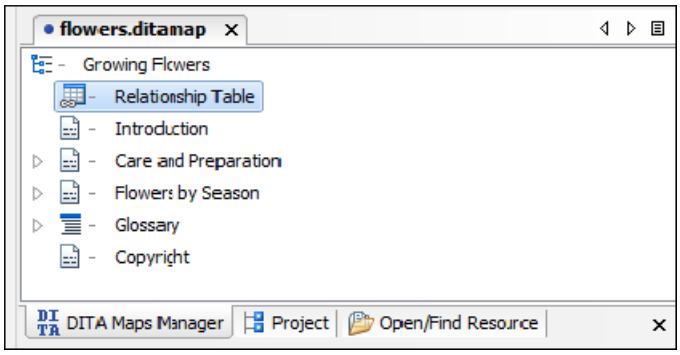

Figure 888: Relationship Table

You can open the DITA map to edit the relationship table by doing one of the following:

- Double-click the appropriate relationship table in the ***DITA Maps Manager***.
- Select the relationship table in the ***DITA Maps Manager*** and press **Enter**.
- Select **Open** from the contextual menu of the relationship table in the ***DITA Maps Manager***.

Publishing DITA Output

As a structured writing format, DITA produces structured content (content that is annotated with specific structural and semantic information rather than with formatting information). To create a publication, your *DITA map* and its associated topics must be processed by a transformation script. That script is responsible for how the structural and semantic information in the DITA files is converted into formatting information for display.

This means that you can display the same DITA content in multiple ways, types of media, or publications. It also means that you cannot control every aspect of the presentation of your content in your DITA files. The only way to change the formatting is to change the transformation routines that create it.

Therefore, to create output from your DITA content you have to run a transformation on your content. Transformations for various types of output are provided by the DITA Open Toolkit. Oxygen XML Editor provides a mechanism called transformation scenarios to help you configure and run transformations.

Note: Oxygen XML Editor does not create any output formats itself. Oxygen XML Editor runs externally defined transformations that produce output, and displays the result in the appropriate application, but the output itself is produced by the external transformation, not by Oxygen XML Editor.

Running a Transformation Scenario

To select and run a transformation scenario on your map, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button on the ***DITA Maps Manager*** *toolbar*. The ***Configure Transformation Scenario(s)*** *dialog box* appears. This dialog box lists all the transformation scenarios that have been configured in your project. Oxygen XML Editor provides a default set of transformation scenarios, but the people in charge of your DITA system may have provided others that are specifically configured for your needs.
2. Select the transformation scenario you want to run and click **Apply Associated**. The transformation scenario runs in the background. You can continue to work in Oxygen XML Editor while the transformation is running. If there are errors or warnings, Oxygen XML Editor displays them when the transformation is complete. If the transformation is successful, Oxygen XML Editor opens the output in the appropriate application.
3. To rerun the same scenario again, click the **Apply Transformation Scenario(s)** button.

Transforming DITA Content

Oxygen XML Editor uses the DITA Open Toolkit (DITA-OT) to transform *DITA maps* and topics into an output format. For this purpose, both the DITA Open Toolkit and Ant come bundled in Oxygen XML Editor.

For more information about the DITA Open Toolkit, see *DITA Open Toolkit Documentation*.

This section includes information about how to create a DITA OT transformation and how to customize DITA transformations.

Related Information:

Transforming Documents on page 1064

Creating or Editing a DITA OT Transformation

Creating a DITA OT Transformation Scenario

To create a **DITA OT Transformation** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s)** (**Ctrl + Shift + C (Command + Shift + C on OS X)**) action from the **DITA Maps Manager** toolbar, main toolbar, or the **Document** > **Transformation** menu. Then click the **New** button and select **DITA OT Transformation**.
- Go to **Window** > **Show View** and select **Transformation Scenarios** to display this view. Click the **New Scenario** drop-down menu button and select **DITA OT Transformation**.

Both methods open the **DITA Transformation Type** dialog box that presents the list of possible outputs.

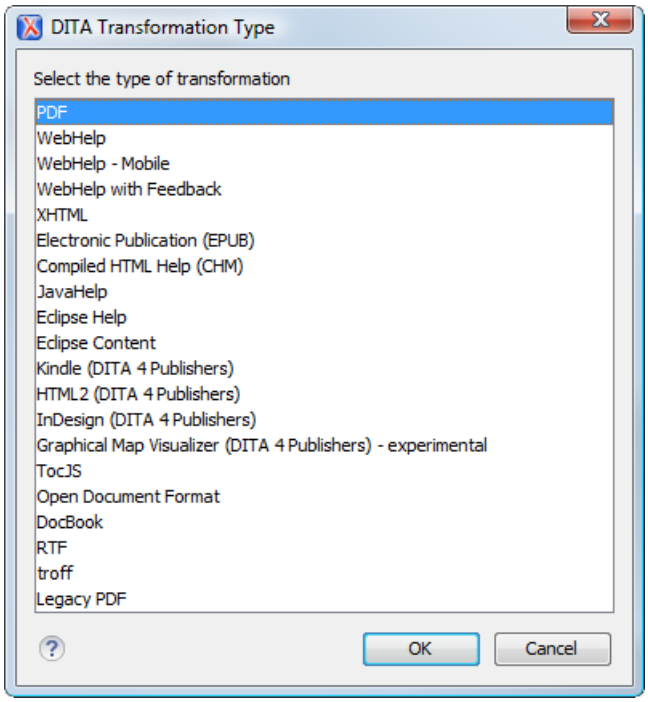

Figure 889: DITA Transformation Type Dialog Box

Select the desired type of output and click **OK**. This opens the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation. Some of these tabs are only available for certain output types (for example, a **Skins** tab is only available for **WebHelp Classic** and **WebHelp Classic with Feedback** output types, a **Templates** tab is available only for **WebHelp Responsive** and **WebHelp Responsive with Feedback**, and a **FO Processor** tab is available for PDF output).

Editing a DITA OT Transformation Scenario

Editing a transformation scenario is useful if you need to configure some of its parameters.

To configure an existing transformation scenario, follow these steps:

1. Select the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the **DITA Maps Manager** toolbar, main toolbar, or the **Document** > **Transformation** menu.

   Step Result: The ***Configure Transformation Scenario(s)*** *dialog box* is opened.
2. Select the particular transformation scenario and click the **Edit** button at the bottom of the dialog box or from the contextual menu.

   Note: Since transformation scenarios that are associated with predefined *frameworks* are read-only, these scenarios will prompt you to use the ***Duplicate*** *button and then edit the duplicated scenario*.

Result: This will open an ***Edit scenario*** *configuration dialog box* that contains several tabs that allow you to configure the options that control the transformation. Some of these tabs are only available for certain output types (for example, a **Skins** tab is only available for **WebHelp Classic** and **WebHelp Classic with Feedback** output

types, a **Templates** tab is available only for **WebHelp Responsive** and **WebHelp Responsive with Feedback**, and a **FO Processor** tab is available for PDF output).

Installing a Plugin in the DITA Open Toolkit on page 1925

DITA Open Toolkit Documentation

Skins Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Skins** tab is available for DITA OT transformations with **WebHelp Classic** or **WebHelp Classic with Feedback** output types and it provides a set of predefined skins that you can use as a base for your WebHelp system output.

A *skin* is a collection of CSS properties that can alter the look of the output by changing colors, font types, borders, margins, and paddings. This allows you to rapidly adapt the look and feel of your output.

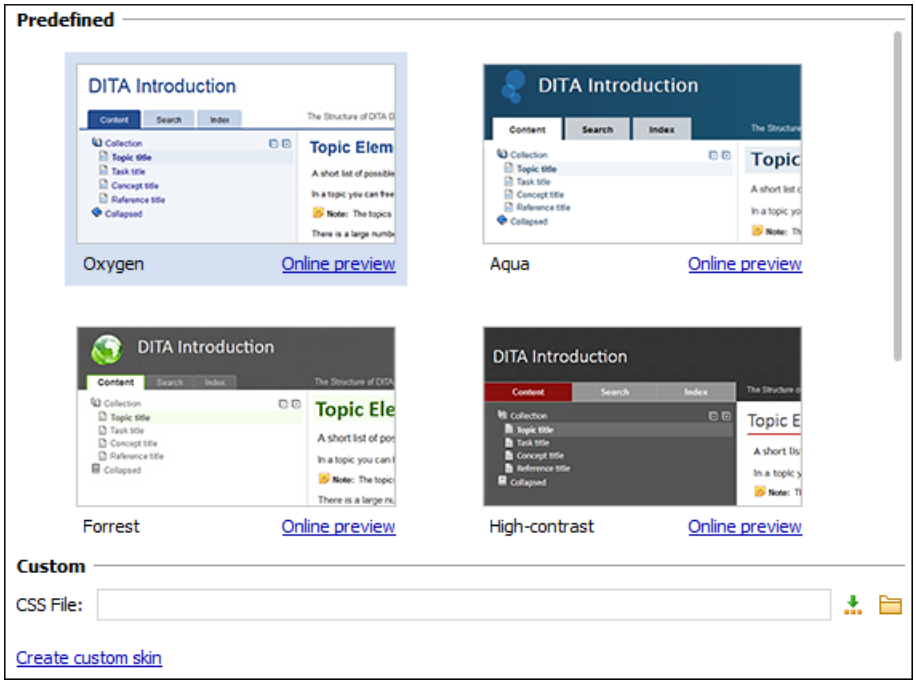

Figure 890: Skins Tab

The **Skins** tab includes the following sections:

Predefined Skins

This sections presents the predefined skins that are included in Oxygen XML Editor. The predefined skins cover a wide range of chromatic themes, ranging from a very light one to a high-contrast variant. To see how the *skin* looks when applied on a sample documentation project that is stored on the Oxygen XML Editor website, press the **Online preview** link.

Custom Skins

You can use this section to customize the look of the output.

CSS File

You can set this field to point to a custom CSS stylesheet or customized skin. A custom CSS file will overwrite a skin selection.

Note: The output can also be styled by setting the `args.css` parameter in the **Parameters tab**. The properties taken from the stylesheet referenced in this parameter take precedence over the properties declared in the skin set in the **Skins tab**.

Create custom skin

Use this link to open the ***WebHelp Skin Builder*** tool.

Templates Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Templates** tab is available for DITA OT transformations with **WebHelp Responsive** or **WebHelp Responsive with Feedback** output types and it provides a set of predefined *skins* that you can use as a base for the layout of your WebHelp system output.

A *skin* is a collection of CSS properties that can alter the look of the output by changing colors, font types, borders, margins, and paddings. This allows you to rapidly adapt the look and feel of your output. You can choose predefined skins in a *tile* style of layout or a *tree* style of layout, and you can also *add your own customized skins*.

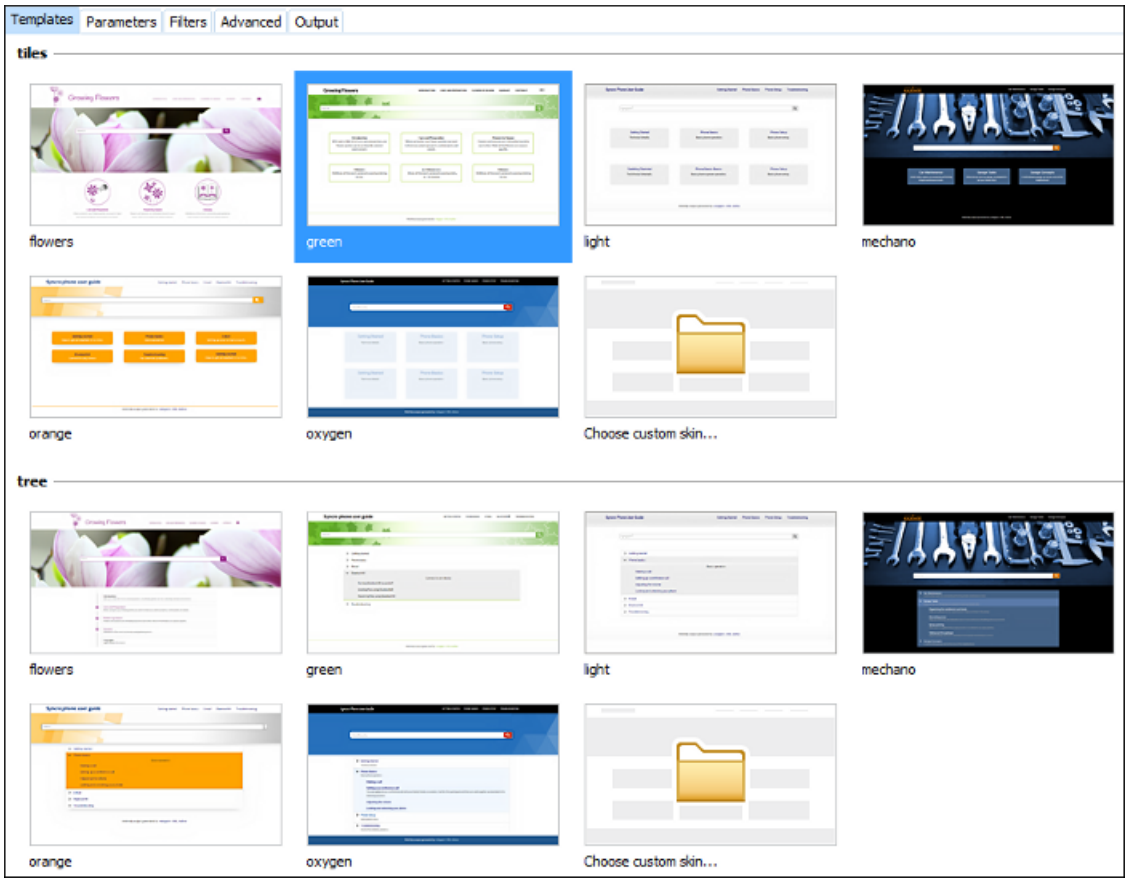

Figure 891: Templates Tab

The **Templates** tab comes by default with the following predefined collections of skins:

Tiles

This sections presents the predefined skins that are arranged in a *tiles* style of layout. These predefined skins include a variety of themes, ranging from a very light one to a high-contrast variant, and various styles. If you select **Choose custom skin**, you can select a custom CSS stylesheet to be used as your template.

Tree

This sections presents the predefined skins that are arranged in a *tree* style of layout. These predefined skins include a variety of themes, ranging from a very light one to a high-contrast variant, and various styles. If you select **Choose custom skin**, you can select a custom CSS stylesheet to be used as your template.

When you add a new collection of skins, this tab will list them.

FO Processor Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab is available for DITA OT transformations with a **PDF** output type.

This tab allows you to select an FO Processor to be used for the transformation.

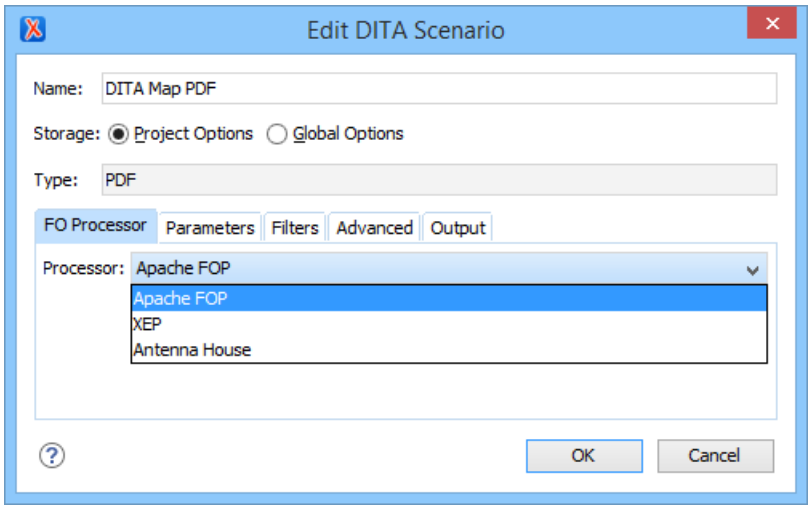

Figure 892: FO Processor Configuration Tab

You can choose one of the following processors:

Apache FOP

The default processor that comes bundled with Oxygen XML Editor.

XEP

The *RenderX* XEP processor. If XEP is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. XEP is considered installed if it was detected in one of the following sources:

- XEP was configured as an external FO Processor in the ***FO Processors** option page*.
- The system property *com.oxygenxml.xep.location* was set to point to the XEP executable file for the platform (for example: `xep.bat` on Windows).
- XEP was installed in the *`DITA-OT-DIR`*`/plugins/org.dita.pdf2/lib` directory of the Oxygen XML Editor installation directory.

Antenna House

The *Antenna House* (AH Formatter) processor. If Antenna House is already installed, Oxygen XML Editordisplays the detected installation path under the drop-down menu. Antenna House is considered installed if it was detected in one of the following sources:

- Environment variable set by Antenna House installation (the newest installation version will be used).
- Antenna House was added as an external FO Processor in the Oxygen XML Editor preferences pages.

To further customize the PDF output obtained from the Antenna House processor, follow these steps:

1. **Edit** the transformation scenario.
2. Open the ***Parameters** tab*.
3. Add the `env.AXF_OPT` parameter and point to the Antenna House configuration file.

Related Information:

FO Processors Preferences on page 130
XSL-FO Processors on page 1149

Parameters Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Parameters** tab allows you to configure the parameters sent to the DITA-OT build file.

The table in this tab displays all the parameters that the DITA-OT documentation specifies as available for each chosen type of transformation (for example, XHTML or PDF), along with their description and current values. You can find more information about each parameter in the *DITA OT Documentation*. You can also add, edit, and remove parameters, and you can use the text box to filter or search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
- A file chooser and an *editor variable* selector to simplify setting a file path as the value of a parameter.

Note: To input parameter values at runtime, use the *ask editor variable* in the **Value** column.

Below the table, the following actions are available for managing parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. You can specify the **Value** of the parameter by using the ***Insert Editor Variables*** button or the **Browse** button.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Edit

Opens the **Edit Parameter** dialog box that allows you to change the value of the selected parameter or its description.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

Related Information:

DITA Open Toolkit Documentation

Filters Tab (DITA Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Filters** tab allows you to add filters to remove certain content elements from the generated output.

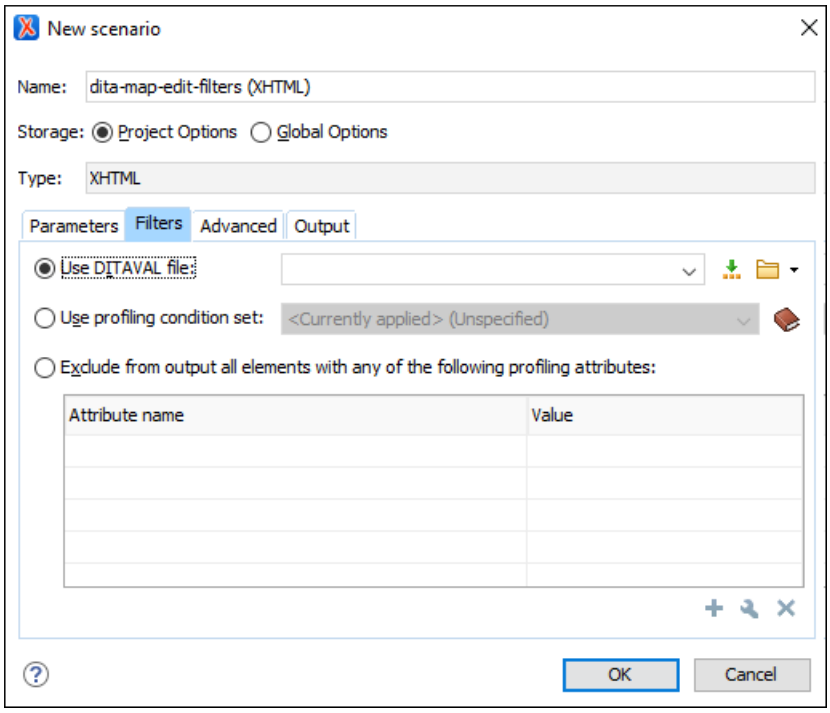

Figure 893: Edit Filters Tab

You can choose one of the following options to define filters:

Use DITAVAL file

If you already have a *DITAVAL* file associated with the *DITA map*, you can specify the file to be used when filtering content. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can find out more about constructing a *DITAVAL* file in the *DITA Documentation*.

Attention: If a filter file is specified in the `args.filter` parameter (in *the **Parameters** tab*), that file takes precedence over a *DITAVAL* file specified here.

Use profiling condition set

Sets the *profiling condition set* that will be applied to your transformation.

Exclude from output all elements with any of the following attributes

By using the **New**, **Edit**, or **Delete** buttons at the bottom of the pane, you can configure a list of attributes (name and value) to exclude all elements that contain any of these attributes from the output.

Advanced Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Advanced** tab allows you to specify advanced options for the transformation scenario.

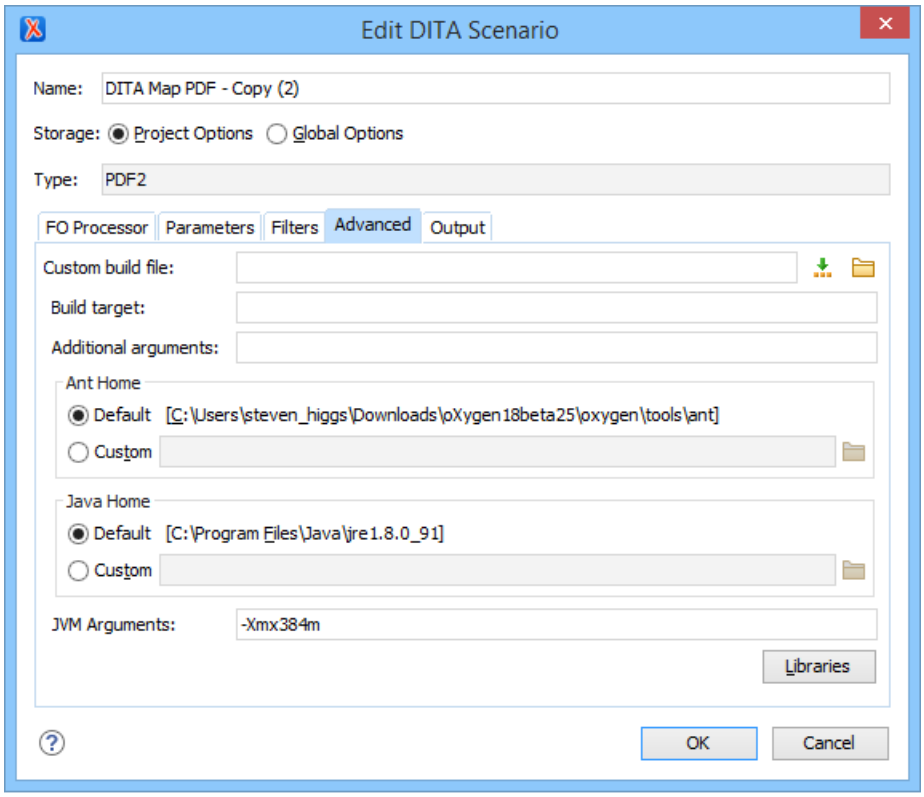

Figure 894: Advanced Settings Tab

You can specify the following parameters:

Custom build file

If you use a custom DITA-OT build file, you can specify the path to the customized build file. If empty, the `build.xml` file from the `dita.dir` parameter that is configured in the ***Parameters** tab* is used. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Build target

Optionally, you can specify a build target for the build file. If no target is specified, the default `init` target is used.

Additional arguments

You can specify additional command line arguments to be passed to the transformation (such as -verbose).

Ant Home

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the *Ant preferences page*.

Java Home

You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

Note: It may be possible that the used Java version is incompatible with the DITA Open Toolkit engine. For example, DITA OT 1.8 and older requires Java 1.6 or later, while DITA OT 2.0 and newer requires Java 1.7 or newer. Thus, if you encounter related errors running the transformation, consider installing a Java VM that is supported by the DITA OT publishing engine and using it in the **Java Home** text field.

JVM Arguments

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. For example, if it is set to -Xmx384m, the transformation process is allowed to use 384 megabytes of memory. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid *Out of Memory* error messages (**OutOfMemoryError**).

Libraries

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (*JAR* files or additional class paths) to be used by the Ant transformer.

Tip: You can specify the path to the additional libraries using wildcards (for example, `${oxygenHome}/lib/*.jar`).

Output Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab allows you to configure options that are related to the location where the output is generated.

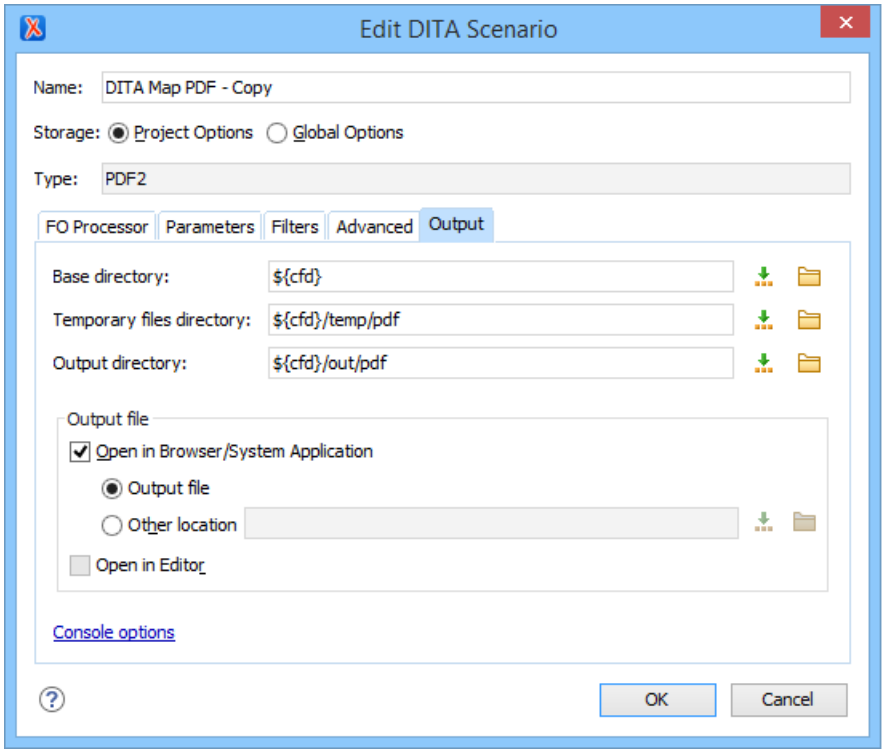

Figure 895: Output Settings Tab

You can specify the following parameters:

Base directory

All the relative paths that appear as values in parameters are considered relative to the base directory. The default value is the directory where the transformed map is located. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Temporary files directory

This directory is used to store pre-processed temporary files until the final output is obtained. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Output directory

The folder where the content of the final output is stored. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Note: If the *DITA map* or topic is opened from a remote location or a ZIP file, the parameters must specify absolute paths.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).

Note: To set the web browser that is used for displaying HTML/XHTML pages, go to **Options** > **Preferences** > **Global**, and set it in the **Default Internet browser** field.

- **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in editor

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

At the bottom of the pane there is a link to the *Console options* preferences page that contains options to control the display of the console output received from the publishing engine.

Customizing DITA Transformations

Oxygen XML Editor includes a bundled copy of the DITA-OT as an Oxygen XML Editor *framework*. That *framework* includes a number of transformation scenarios for common output formats. This section includes topics about customizing DITA transformations, such as using a custom build file, customizing PDF output, and using DITA OT *plugins* to customize your needs.

Customizing Output Transformations

You can customize the appearance of any of the output types by customizing the output transformations. There are several ways to do this:

- Most transformations are configurable by passing parameters to the transformation script. Oxygen XML Editor allows you to *set parameters* on a transformation scenario and you can *save and share them with others*. You can also use the ***${ask}*** *editor variable* in the **Parameters** tab to instruct Oxygen XML Editor to prompt you for a particular parameter whenever a transformation scenario is run. You can set up multiple transformation scenarios for a given output type, allowing you to maintain several customized transformation scenarios for multiple types of output configurations.
- If you want to customize an output in a way not supported by the customization options, you can create a modified version of the transformation code. Some transformation scripts export specific forms of extension or customization. You should consult the DITA Open Toolkit for the transformation type that you are interested in to see what customization options it supports. Oxygen XML Editor provides full editing and *debugging support from XSLT and CSS stylesheets*, which you can use to modify transformation code.

You can also write your own output transformation scripts to produce a type of output not supported by the DITA Open Toolkit. Oxygen XML Editor provides a full source editing environment for developing such transformations. You can create Oxygen XML Editor transformation scenarios to run these scripts once they are complete.

Related Information:

Transforming DITA Content on page 1887

DITA Open Toolkit Documentation

Using a Custom Build File

To use a custom build file in a DITA-OT transformation, follow these steps:

1. Use the **Configure Transformation Scenario(s)** action to open the ***Configure Transformation Scenario(s)*** *dialog box*.
2. Select the transformation scenario and click **Edit**.
3. Go to the ***Advanced*** tab and change the **Custom build file** path to point to the custom build file.

As an example, if you want to call a custom script before running the DITA OT, your custom build file would have the following content:

```
<project basedir="." default="dist">
<!--The DITA OT default build file-->
 <import file="build.xml"/>
 <target name="dist">
  <!-- You could run your script here -->
  <!--<exec></exec>-->
   <!--Call the DITA OT default target-->
   <antcall target="init"/>
 </target>
</project>
```

Note: If you use the built-in Ant 1.8.2 build tool that comes bundled with Oxygen XML Editor, it is located in the *[OXYGEN_INSTALL_DIR]*`/tools/ant` directory. Any additional libraries for Ant must be copied to the Oxygen XML Editor Ant `lib` directory.

DITA Map to PDF Output Customization

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting *DITA maps* to PDF output. There are numerous ways that you can customize the PDF output and the topics in this section discuss some of those possibilities.

Creating a DITA Map to PDF Transformation Scenario

To create a *DITA Map to PDF* transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF** and click the **Edit** button (or use the **Duplicate** button if your *framework* is read-only).
3. Use the various tabs to configure the transformation scenario. In the **Parameters** tab, you can use a variety of parameters to customize the output. For example, the following parameters are just a few of the most commonly used ones:
   - `show.changes.and.comments` - If set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output.
   - `customization.dir` - Specifies the path to a customization directory.
4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.

Customizing the PDF Output

DITA Open Toolkit PDF output can be customized in several ways:

- Creating a DITA Open Toolkit plugin that adds extensions to the PDF plugin. More details can be found in the *DITA Open Toolkit Documentation*.
- Creating a customization directory and using it from the PDF transformation scenario. A small example of this procedure can be found below.

How to Create a Customization Directory for PDF Output

The following procedure explains how to do a basic customization of the PDF output by setting up a customization directory. An example of a common use case is embedding a company logo image in the front matter of the book.

1. Copy the entire directory: *`DITA-OT-DIR`*`\plugins\org.dita.pdf2\Customization` to another location (for instance, `C:\Customization`).
2. Copy your logo image to: `C:\Customization\common\artwork\logo.png`.
3. Rename `C:\Customization\catalog.xml.orig` to: `C:\Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and *uncomment* this line:

   ```
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->
   ```

   It now looks like this:

   ```
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```

5. Rename the file: `C:\Customization\fo\xsl\custom.xsl.orig` to: `C:\Customization\fo\xsl\custom.xsl`
6. Open the `custom.xsl` file in Oxygen XML Editor and create the template called **createFrontCoverContents** for DITA-OT 2.5.2 (or createFrontMatter_1.0 for DITA-OT 1.8.5).

   Tip: You can copy the same template from *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl` and modify it in whatever way necessary to achieve your specific goal. This new template in the `custom.xsl` file will override the same template from *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl`.

   DITA OT 2.5.2 Example:

   For example, if you are using DITA OT 2.5.2, the `custom.xsl` could look like this:

```
<?xml version='1.0'?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:fo="http://www.w3.org/1999/XSL/Format"
    version="2.0">

<xsl:template name="createFrontCoverContents">
 <!-- set the title -->
 <fo:block xsl:use-attribute-sets="__frontmatter__title">
  <xsl:choose>
   <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
    <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
      </xsl:when>
      <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
        <xsl:apply-templates select="$map//*[contains
                                    (@class,' bookmap/mainbooktitle ')][1]"/>
      </xsl:when>
      <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
        <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
      </xsl:when>
      <xsl:otherwise>
        <xsl:value-of select="/descendant::*[contains
           (@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
   </xsl:otherwise>
  </xsl:choose>
 </fo:block>

 <!-- set the subtitle -->
 <xsl:apply-templates select="$map//*[contains
                                    (@class,' bookmap/booktitlealt ')]"/>
 <fo:block xsl:use-attribute-sets="__frontmatter__owner">
  <xsl:apply-templates select="$map//*[contains(@class,' bookmap/bookmeta ')]"/>
 </fo:block>

 <!-- Load the image logo -->
  <fo:block text-align="center" width="100%">
   <fo:external-graphic
      src="url({concat($artworkPrefix,
                       '/Customization/OpenTopic/common/artwork/logo.png')})"
    />
 </fo:block>
 </xsl:template>

</xsl:stylesheet>
```

   DITA OT 1.8.5 Example:

   For example, if you are using DITA OT 1.8.5, the `custom.xsl` could look like this:

```
<?xml version='1.0'?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:fo="http://www.w3.org/1999/XSL/Format"
    version="1.1">

<xsl:template name="createFrontMatter_1.0">
   <fo:page-sequence master-reference="front-matter"
                        xsl:use-attribute-sets="__force__page__count">
     <xsl:call-template name="insertFrontMatterStaticContents"/>
       <fo:flow flow-name="xsl-region-body">
          <fo:block xsl:use-attribute-sets="__frontmatter">
     <!-- set the title -->
           <fo:block xsl:use-attribute-sets="__frontmatter__title">
            <xsl:choose>
             <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
     <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
                 </xsl:when>
    <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
     <xsl:apply-templates select="$map//*[contains
                                    (@class,' bookmap/mainbooktitle ')][1]"/>
         </xsl:when>
    <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
      <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
         </xsl:when>
      <xsl:otherwise>
```

```
    <xsl:value-of select="/descendant::*[contains
          (@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
      </xsl:otherwise>
        </xsl:choose>
     </fo:block>

  <!-- set the subtitle -->
     <xsl:apply-templates select="$map//*[contains
                                        (@class,' bookmap/booktitlealt ')]"/>

        <fo:block xsl:use-attribute-sets="__frontmatter__owner">
            <xsl:apply-templates select="$map//*[contains
                                            (@class,' bookmap/bookmeta ')]"/>
        </fo:block>

        <fo:block text-align="center" width="100%">
           <fo:external-graphic src="url({concat($artworkPrefix,
                      '/Customization/OpenTopic/common/artwork/logo.png')})"/>
         </fo:block>

    </fo:block>

   <!--<xsl:call-template name="createPreface"/>-->

            </fo:flow>
        </fo:page-sequence>
        <xsl:call-template name="createNotices"/>
    </xsl:template>
</xsl:stylesheet>
```

7. Edit the **DITA Map PDF** transformation scenario and in the **Parameters** tab, set the customization.dir parameter to `C:\Customization`.

Tip: For other specific examples, see *DITA-OT 2.x Documentation - PDF Customization Plugin*.

Customizing the Header and Footer in PDF Output

The XSLT stylesheet *DITA-OT-DIR*`/plugins/org.dita.pdf2/xsl/fo/static-content.xsl` contains templates that output the static header and footers for various parts of the PDF such as the prolog, table of contents, front matter, or body.

The templates for generating a footer for pages in the body are called `insertBodyOddFooter` or `insertBodyEvenFooter`.

These templates get the static content from resource files that depend on the language used for generating the PDF. The default resource file is *DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg/common/vars/en.xml`. These resource files contain variables (such as *Body odd footer*) that can be set to specific user values.

Instead of modifying these resource files directly, they can be overwritten with modified versions of the resources in a PDF customization directory as explained in *Customizing the PDF Output* on page 1897.

Adding a Watermark to PDF Output

To add a watermark to the PDF output of a *DITA map* transformation, create a DITA-OT customization directory and use it from a **DITA Map to PDF** transformation scenario, as in the following procedure:

1. Copy the entire directory: *DITA-OT-DIR*`\plugins\org.dita.pdf2\Customization` to another location (for instance, `C:\Customization`).
2. Copy your watermark image (for example, `watermark.png`) to: `C:\Customization\common\artwork\watermark.png`.
3. Rename the `C:\Customization\catalog.xml.orig` file to: `C:\Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and *uncomment* this line:

   ```
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->
   ```

   The uncommented line should look like this:

   ```
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```

5. Rename the file: `C:\Customization\fo\xsl\custom.xsl.orig` to: `C:\Customization\fo\xsl\custom.xsl`
6. Open the `C:\Customization\fo\xsl\custom.xsl` file in Oxygen XML Editor to overwrite two XSLT templates:
   - The first template is located in the XSLT stylesheet *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\static-content.xsl` and we override it specifying a watermark image for every page in the PDF content, using a *block-container* element that references the watermark image file:

```
<fo:static-content flow-name="odd-body-header">
       <fo:block-container absolute-position="absolute"
          top="-2cm" left="-3cm" width="21cm" height="29.7cm"
          background-image="{concat($artworkPrefix,
'/Customization/OpenTopic/common/artwork/watermark.png')}">
         <fo:block/>
       </fo:block-container>
      <fo:block xsl:use-attribute-sets="__body__odd__header">
          <xsl:call-template name="insertVariable">
              <xsl:with-param name="theVariableID" select="'Body odd header'"/>
              <xsl:with-param name="theParameters">
                 <prodname>
                     <xsl:value-of select="$productName"/>
                 </prodname>
                 <heading>
                <fo:inline xsl:use-attribute-sets="__body__odd__header__heading">
                       <fo:retrieve-marker retrieve-class-name="current-header"/>
                </fo:inline>
                 </heading>
                <pagenum>
               <fo:inline xsl:use-attribute-sets="__body__odd__header__pagenum">
                      <fo:page-number/>
               </fo:inline>
             </pagenum>
        </xsl:with-param>
      </xsl:call-template>
    </fo:block>
  </fo:static-content>

</xsl:template>
```

   - The second template that we override is located in the XSLT stylesheet *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\commons.xsl` and is used for styling the first page of the output. We also override it by copying the original template content in our `custom.xsl` and adding the `block-container` element that references the watermark image file:

```
<xsl:template name="createFrontMatter_1.0">
      <fo:page-sequence master-reference="front-matter"
xsl:use-attribute-sets="__force__page__count">
          <xsl:call-template name="insertFrontMatterStaticContents"/>
          <fo:flow flow-name="xsl-region-body">
              <fo:block-container absolute-position="absolute"
                  top="-2cm" left="-3cm" width="21cm" height="29.7cm"
                  background-image="{concat($artworkPrefix,
'/Customization/OpenTopic/common/artwork/watermark.png')}">
                <fo:block/>
              </fo:block-container>
  <fo:block xsl:use-attribute-sets="__frontmatter">
      <!-- set the title -->
    <fo:block xsl:use-attribute-sets="__frontmatter__title">
     <xsl:choose>
      <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
    <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
      </xsl:when>
      <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
    <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/mainbooktitle ')][1]"/>
          </xsl:when>
          <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
              <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
          </xsl:when>
            <xsl:otherwise>
             <xsl:value-of select="/descendant::*[contains
(@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
            </xsl:otherwise>
      </xsl:choose>
    </fo:block>

   <!-- set the subtitle -->
   <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/booktitlealt ')]"/>

      <fo:block xsl:use-attribute-sets="__frontmatter__owner">
         <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/bookmeta ')]"/>
      </fo:block>

      </fo:block>
```

```
<!--<xsl:call-template name="createPreface"/>-->

   </fo:flow>
     </fo:page-sequence>
     <xsl:if test="not($retain-bookmap-order)">
         <xsl:call-template name="createNotices"/>
     </xsl:if>
 </xsl:template>
```

7. Edit your **DITA Map PDF** transformation scenario. In the **Parameters** tab, set the customization.dir parameter to `C:\Customization`.

Related Information:
Adding a Watermark in DITA Map to XHTML Output on page 1906

Adding an Edit Link in PDF Output to Launch Oxygen XML Web Author

You can embed *Edit* links in the DITA Map PDF output that will automatically launch a particular document in *Oxygen XML Web Author*. A reviewer can then simply click the link and they will be redirected to the Oxygen XML Web Author editing page with that particular file open and editable.

To embed an *Edit* link in the DITA Map PDF output, follow these steps:

1. *Edit a **DITA Map PDF** transformation scenario* and open the **Parameters** tab.
2. Set values for the following parameters:
   - **editlink.remote.ditamap.url** - The URL of the DITA Map suitable for opening in Oxygen XML Web Author.
   - **editlink.web.author.url** - The URL of the Oxygen XML Web Author installation.
3. Run the transformation scenario.

Result: In the PDF output, all topics will have an **Edit** link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

Force Page Breaks Between Two Block Elements in PDF Output

Suppose that in your DITA content you have two *block elements*, such as two paragraphs:

```
<p>First para</p>
<p>Second para</p>
```

and you want to force a page break between them in the PDF output.

Here is how you can implement a DITA Open Toolkit *plugin* that would achieve this:

1. Define your custom processing instruction that marks the place where a page break should be inserted in the PDF, for example:

   ```
   <p>First para</p>
     <?pagebreak?>
   <p>Second para</p>
   ```

2. Locate the **DITA Open Toolkit** distribution and in the `plugins` directory create a new *plugin* folder (for example, *`DITA-OT-DIR`*`/plugins/pdf-page-break`).
3. In this new folder, create a new `plugin.xml` file with the following content:

   ```
   <plugin id="com.yourpackage.pagebreak">
     <feature extension="package.support.name" value="Force Page Break Plugin"/>
     <feature extension="package.support.email" value="support@youremail.com"/>
     <feature extension="package.version" value="1.0.0"/>
     <feature extension="dita.xsl.xslfo" value="pageBreak.xsl" type="file"/>
   </plugin>
   ```

   The most important feature in the *plugin* is that it will add a new XSLT stylesheet to the XSL processing that produces the PDF content.
4. In the same folder, create an XSLT stylesheet named `pageBreak.xsl` with the following content:

   ```
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                       xmlns:fo="http://www.w3.org/1999/XSL/Format"version="1.0">
     <xsl:template match="processing-instruction('pagebreak')">
       <fo:block break-after="page"/>
     </xsl:template>
   </xsl:stylesheet>
   ```

5. *Install your plugin in the DITA Open Toolkit.*

Customizing `note` Images in PDF

To customize the images that appear next to each type of note in the PDF output, use a *PDF customization folder* with the following procedure:

1. Copy the *DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg/common/vars/en.xml` file to the `[CUSTOMIZATION_DIR]\common\vars` folder.
2. Edit the copied `en.xml` file and modify, for example, the path to the image for `<note>` element with the `type` attribute set to `notice` from:

   ```
   <variable id="notice Note Image
     Path">Configuration/OpenTopic/cfg/common/artwork/important.png</variable>
   ```

   to:

   ```
   <variable id="notice Note Image
     Path">Customization/OpenTopic/common/artwork/notice.gif</variable>
   ```
3. Add your custom **notice** image to `[CUSTOMIZATION_DIR]\common\artwork\notice.gif`.
4. Edit the **DITA Map PDF** transformation scenario and in the **Parameters** tab set the path for the customization.dir property to point to the customization folder. Also, set the **com.oxygenxml.use.custom.note.images** parameter to **no**.

Show Comments and Tracked Changes in PDF Output

To include comments and *tracked changes* (stored within your DITA topics) in the PDF output, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF** and click the **Edit** button (or use the **Duplicate** button if your *framework* is read-only).
3. In the **Parameters** tab, set the value of the show.changes.and.comments parameter to `yes`.
4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.

   Result: Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

Set a Font for PDF Output Generated with FO Processor

When a *DITA map* is transformed to PDF using an FO processor and it contains some Unicode characters that cannot be rendered by the default PDF fonts, a font that is capable of rendering these characters must be configured and embedded in the PDF result.

The settings that must be modified for configuring a font for the built-in FO processor are detailed in *Add a Font to the Built-in FO Processor* on page 1150.

DITA OT PDF Font Mapping

The DITA OT contains a file *DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml` that maps logical fonts used in the XSLT stylesheets to physical fonts that will be used by the FO processor to generate the PDF output.

The XSLT stylesheets used to generate the XSL-FO output contain code like this:

```
<xsl:attribute name="font-family">monospace</xsl:attribute>
```

The font-family is defined to be *monospace*, but *monospace* is just an alias. It is not a physical font name. Therefore, another stage in the PDF generation takes this *monospace* alias and looks in the `font-mappings.xml`.

If it finds a mapping like this:

```
<aliases>
      <alias name="monospace">Monospaced</alias>
 </aliases>
```

then it looks to see if the *Monospaced* has a *logical-font* definition and if so, it will use the *physical-font* specified there:

```
<logical-font name="Monospaced">
      <physical-font char-set="default">
        <font-face>Courier New, Courier</font-face>
      </physical-font>
.............
</logical-font>
```

Important:

If no alias mapping is found for a font-family specified in the XSLT stylesheets, the processing defaults to **Helvetica**.

Related Information:

DITA Map to PDF WYSIWYG Transformation

Oxygen XML Editor comes bundled with a DITA OT plugin that allows you to convert *DITA maps* to PDF using a CSS layout processor. Oxygen XML Editor also comes bundled with a built-in CSS-based PDF processing engine called **Chemistry**. For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations.

Oxygen XML Editor supports the following processors (not included in the Oxygen XML Editor installation kit):

- **Oxygen Chemistry** - A built-in processor that is bundled with Oxygen XML Editor. For more information, see the *Oxygen PDF Chemistry User Guide*.
- **Prince Print with CSS** - A third-party component that needs to be purchased from *http://www.princexml.com*.
- **Antenna House Formatter** - A third-party component that needs to be purchased from *http://www.antennahouse.com/antenna1/formatter/*.

The DITA-OT plugin is located in the following directory: *`DITA-OT-DIR`*`/plugins/com.oxygenxml.pdf.css`.

Although it includes a set of CSS files in its `css` subfolder, when this plugin is used in Oxygen XML Editor, the CSS files located in the `${frameworks}` directory take precedence.

Creating the Transformation Scenario

To create an **DITA Map to PDF WYSIWYG** transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF - WYSIWYG**.
3. In the **CSS Processor** tab, choose the processor type. You can select between **Oxygen PDF Chemistry**, **Prince XML**, or **Antenna House**.
4. In the **Parameters** tab, configure any of the following parameters (if applicable):
   - `css.processor.path.prince` (if you are using the **Prince Print with CSS** processor) - Specifies the path to the Prince executable file that will be run to produce the PDF. If you installed Prince using its default settings, you can leave this blank.
   - `css.processor.path.antenna-house` (if you are using the **Antenna House Formatter** processor) - Specifies the path to the Antenna House executable file that will be run to produce the PDF. If you installed Antenna House using its default settings, you can leave this blank.
   - `show.changes.and.comments` - When set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output. The default value is no.
   - `dita.css.list` - Allows you to specify a list of CSS URLs to be used by the PDF processor (instead of the default CSS files). The files must have URL syntax and be separated using semicolons. If the value is empty, the CSS associated with the current selection from the **Styles** drop-down menu is used.
   - `args.css` - Allows you to specify a list of CSS URLs to be used in addition to those specified in the `dita.css.list` parameter OR in addition to the CSS that is currently selected in the **Styles** drop-down menu. The files must have URL syntax and be separated using semicolons. Also, the `dita.css.list` parameter must be left empty to use these files in addition to the selection in the **Styles** drop-down menu.
5. Click **OK** and run the transformation scenario.

Customizing the Styles (for Output and Editing)

If you need to change the styles in the associated CSS, make sure you install Oxygen XML Editor in a folder where you have full read and write privileges (for instance, your user home directory). This is due to the fact that the installed files are usually placed in a read-only folder (for instance, in Windows, Oxygen XML Editor is installed in the `Program Files` folder where the users do not have change rights).

To change the styles of an element you need to create an additional CSS file that will store the customization rules. Once you have created this file, you need to instruct the editor how to use this additional CSS. This can be done in two ways:

- Create an alternate CSS for the DITA document type:
  1. Follow the procedure for adding an alternate CSS file in *Customizing the Main CSS of a Framework* on page 1454.
  2. Once you have configured your CSS as an additional layer, you can *select it from the **Styles** drop-down menu (on the toolbar)*.
  3. Run the **DITA Map PDF - WYSIWYG** transformation scenario and the customization rules from the additional CSS will be visible in the produced PDF.

  This method allows you to have many customization CSS files and simply select the one that you need at any time for both the output and rendering **Author** mode while editing.
- Use the `args.css` parameter that allows you to specify a list of CSS URLs to be used in addition to the `dita.css.list` parameter:
  1. Configure a **DITA map to PDF WYSIWYG** transformation scenario, as described in the procedure *above*.
  2. In the **Parameters** tab, specify the path to your custom CSS files in the `args.css` parameter.
  3. Click **OK** and run the transformation scenario.

  This method is appropriate if you just want to apply the styling customization to the output.

Tip: For more information about customizing CSS styles for PDF output, see the *Oxygen PDF Chemistry User Guide*. It offers numerous tips for customizing CSS styles even if you are not using the Chemistry processor.

Using the CSS Inspector to See Style Associated with an Element

To find the styles associated with an element, follow this procedure:

1. Open a document in the editor and select **Inspect Styles** from the contextual menu. This opens the ***CSS Inspector** view* that shows all the CSS rules that apply to the selected element.
2. Click the particular link for the CSS selector that you need to change and Oxygen XML Editor will open the CSS file and position the cursor at that selector.
3. After you identify the source of the styles you want to modify, copy the CSS rule in your customization CSS file and modify it according to your needs.

   To see the changes in **Author** mode, press **F5** to reload the document.

How to Make Remote Resources Appear in the Output When Using the Prince Processor

If your documentation references external resources (such as images that are stored on a Web-based repository) and your system is behind an HTTP(S) proxy, you may find that they do not appear in the output when using the **Prince Print with CSS** processor. To solve this, follow this procedure:

1. Edit the **`build.xml`** file that is located in *`DITA-OT-DIR`*`/plugins/com.oxygenxml.pdf.css`.
2. There are two instances in the file where a pair of arguments are commented out:

```
<!-- Please remove the comment wrapping the following two arguments
if you are behind a proxy and your documentation refers remote resources,
for example images.

Note: You also need to remove the backslash '\' that appears before the
property name: "http-proxy". That backslash is there because a sequence of
two dashes ('-') is not permited inside a comment.
-->
<!--
  <arg value="-\-http-proxy=${http.proxyHost}:${http.proxyPort}"/>
  <arg value="-\-http-proxy=${https.proxyHost}:${https.proxyPort}"/>
-->
```

3. Remove the comment in both instances.
4. Make sure you also remove the slash that appears before the property name `http-proxy` in each instance.

   Step Result: The arguments should now look like this:

   ```
   <arg value="--http-proxy=${http.proxyHost}:${http.proxyPort}"/>
   <arg value="--http-proxy=${https.proxyHost}:${https.proxyPort}"/>
   ```
5. Save the **`build.xml`** file.
6. Run the *DITA map to PDF WYSIWYG transformation scenario*.

   Result: Your external resources should now appear in your output.

Customizing CSS Styles Using Oxygen PDF Chemistry

Oxygen PDF Chemistry makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations. It allows you to style the PDF output by simply changing the CSS and then re-running the transformation scenario until you get the desired result.

For more information, see the *Oxygen PDF Chemistry User Guide*. It also offers numerous tips for customizing CSS styles for PDF output even if you are not using the Chemistry processor.

DITA Map to MS Office Word Transformation

Oxygen XML Editor comes bundled with a transformation scenario that allows you to convert *DITA maps* to Microsoft Office Word documents. It utilizes the ***DITA to Word plugin*** *created by Jarno Elovirta*. This *plugin* contains a Word document named **Normal.docx** (located in: *`[OXYGEN_INSTALL_DIR]`*`/frameworks/dita/DITA-OT2.x/plugins/com.elovirta.ooxml/resources`) that is used by the transformation scenario as a template to generate the final Word document.

Tip: You can make general modifications to the **Normal.docx** template file to alter the published output.

Configuring the Transformation Scenario

To configure an **DITA Map to MS Office Word** transformation scenario, follow these steps:

1. Open the DITA map in the ***DITA Maps Manager***.
2. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
3. Select **DITA Map MS Office Word**.
4. For advanced customizations, in the **Parameters** tab you can use any of the following parameters that are unique to this transformation scenario to specify paths to files that affect the output in various ways:
   - `dotx.file` - Specifies the path to a Word template file (`.docx`) that will be used in the transformation to generate the final Word document. Set this parameter if you want to use a different template file other than the **Normal.docx** file that is used by default.
   - `document.flat.xsl` - Specifies the path to a pre-process clean-up stylesheet.
   - `core.xsl` - Specifies the path to a core metadata stylesheet.
   - `custom.xsl` - Specifies the path to a custom metadata stylesheet.
   - `document.xsl` - Specifies the path to a main document stylesheet.
   - `comments.xsl` - Specifies the path to a comments stylesheet.
   - `numbering.xsl` - Specifies the path to a list and title numbering stylesheet.
   - `footnotes.xsl` - Specifies the path to a footnote stylesheet.
   - `document.xml.xsl` - Specifies the path to a document relations metadata stylesheet.
   - `inkscape.exec` - Specifies the path to an Inkscape (open-source vector graphics editor) executable file.

5. Click **OK** and run the transformation scenario.

Result: The result of the transformation will automatically be opened in your system's default word processing application (such as Microsoft Word).

Migrating MS Office Documents to DITA on page 1930

Adding a Watermark in DITA Map to XHTML Output

To add a watermark to the XHTML output of a *DITA map* transformation, follow these steps:

1. Create a custom CSS stylesheet that includes the watermark image, as in the following example:

```
body {
 background-image: url(MyWatermarkImage.png);
}
```

2. Edit a **DITA Map XHTML** transformation scenario and in the **Parameters** tab set the value of the `args.css` parameter as the path to your watermark image.
3. Set the value of the `args.copycss` parameter to **yes**.
4. Apply the transformation scenario.
5. Copy the watermark image in the output directory of the transformation scenario, next to the CSS file created in step 1.

Related Information:
Adding a Watermark to PDF Output on page 1899

DITA Profiling / Conditional Text

DITA offers support for conditionally profiling content by using profiling attributes. With Oxygen XML Editor, you can define values for the DITA profiling attributes and they can be easily managed to filter content in the published output. You can switch between profile sets to see how the edited content looks like before publishing. The profiling configuration can also be shared between content authors through the project file and there is no need for coding or editing configuration files.

Oxygen XML Editor includes a ***Profiling/Conditional Text*** *preferences page* where you can create and manage profiling attributes and condition sets. Oxygen XML Editor also offers convenient support for customizing and controlling profiling attribute values with a *subject scheme* or *DITAVAL file*.

Profiling Attributes

You can profile content elements or map elements by adding one or more of the default DITA profiling attributes (`product`, `platform`, `audience`, `rev`, `props`, and `otherprops`). You can also create your own custom profiling attributes and profiling condition sets. The profiling attributes may contain one or more tokens that represent conditions to be applied to the content when a publication is built.

For example, you could define a section of a topic that would only be included for a publication related to the Windows platform by adding the `platform` profiling attribute:

```
<section platform="windows">
```

For information about creating and editing profiling attributes, see *Creating and Editing Profiling Attributes in DITA* on page 1907 (for information about sharing them, see *Sharing Profiling Attribute Configurations* on page 1908).

Profiling Conditions

DITA allows you to conditionally profile parts of a topic so that certain parts of the topic are displayed when certain profiling conditions are set. Profiling conditions can be set both within topics and in maps. When set in a topic, they allow you to suppress an element (such as paragraph), step in a procedure, item in a list, or even a

phrase within a sentence. When set in a map, they allow you to suppress an entire topic or group of topics. You can then create a variety of publications from a single map by applying profiling conditions to the build.

For information about creating and editing condition sets, see *Creating and Editing Profiling Condition Sets in DITA* on page 1910 (for information about sharing them, see *Sharing Condition Set Configurations* on page 1912).

For more information about DITA profiling, watch our video demonstration:

Creating and Editing Profiling Attributes in DITA

You can filter DITA content or the structure of a document by using profiling attributes or *profiling conditions sets*.

Defining Profiling Attributes for DITA Content

To define or edit profiling attributes for filtering DITA content, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Editor** > **Edit modes** > **Author** > **Profiling / Conditional Text**.
2. In the ***Profiling Attributes** section*, there are already some default attributes for DITA documents (`audience`, `platform`, `product`, `otherprops`, and `rev`), although if a *Subject Scheme Map* is used for profiling your content, you will see the attributes defined in your *subject scheme map* instead. You can add new attributes and values by clicking the **New** button at the bottom of the table, or customize existing attributes and their values by selecting an attribute and clicking the **Edit** button.

   Step Result: This opens a **Profiling Attribute** configuration dialog box that allows you to define attributes that exist in your schema.
3. In this configuration dialog box, use the **New**, **Edit**, **Delete** buttons to add, edit, or delete possible values of the selected attribute. You can also specify an optional description for each attribute value and you can choose whether the attribute accepts a **Single value** or **Multiple values separated by** a delimiter (DITA only accepts *space* as delimiters for attribute values).
4. Click **OK** to accept your changes.

Result: You should see your changes in the **Profiling Attribute** table.

You can also use the **Profiling Condition Sets** section to apply more complex filters on you DITA content.

Editing Profiling Attribute Values

There are several ways to add values to existing profiling attributes.

- Use the procedure in *Defining Profiling Attributes for DITA Content* on page 1907 to edit an existing attribute and use the **Profiling Attribute** configuration dialog box to add, edit, or delete values for existing profiling attributes.
- You can add values directly to the existing profiling attributes in a document using the *In-Place Attributes Editor* in **Author** mode, the ***Attributes** view*, or in the source code in **Text** mode. However, this just adds them to the document and does not change the conditional text configuration. If you invoke the **Edit Profiling Attributes** action (from the contextual menu in **Author** mode) on the new value, the **Profiling Values Conflict** dialog box will appear and it includes an **Add these values to the configuration** action that will automatically add the new value to the particular profiling attribute. It also includes an **Edit the configuration** action that opens the ***Profiling / Conditional Text** preferences page* where you can edit the profiling configuration. The action selected by default is to preserve the current configuration.

  Note: If the ***Allow additional profiling attribute values collected from the document*** option is not selected in the **Profiling / Conditional Text** preferences page, the **Profiling Values Conflict** dialog box will never appear, the current conditional text configuration will be preserved, and therefore the second method mentioned above will not be available.

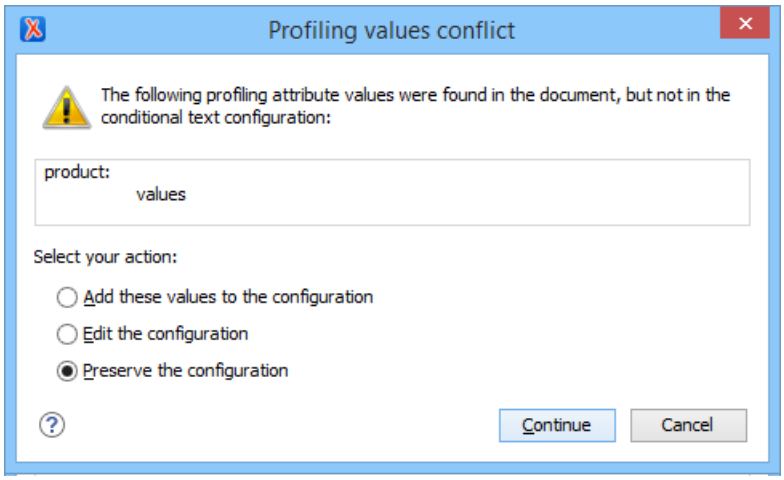

Figure 896: Profiling Values Conflict Dialog Box

Sharing Profiling Attribute Configurations

Your profiling configuration can be shared with other users through a project file. If you select ***Project Options*** at the bottom of the **Profiling/Conditional Text** preferences page, your configuration is stored in the project file and can be shared with others. For instance, if your project file is saved on a version control system (such as SVN, CVS, or Source Safe) or in a shared folder, your team will have the same option configuration that you stored in the project file.

For more information about sharing project files, see *Sharing a Project - Team Collaboration* on page 464.

Applying Profiling Attributes in DITA

Profiling attributes are applied on element nodes. You can apply profiling attributes on a text fragment (it will automatically be wrapped into a phrase-type element), on a single element, or on multiple elements in the same time. If there is no selection in your document, the profiling attributes are applied on the element at the cursor position.

You can apply *defined DITA profiling attributes* as follows:

DITA Topics

To profile DITA topics, right-click a topic reference in the ***DITA Maps Manager***, select **Edit Properties** from the contextual menu, go to the **Profiling** tab, and select the appropriate values.

DITA Content

To profile DITA content in **Author** mode, highlight the content and select **Edit Profiling Attributes** from the contextual menu and select the appropriate values in the **Edit Profiling Attributes** dialog box.

DITA Elements

To profile specific XML elements in **Author** mode, position the cursor inside the element, right-click, select **Edit Profiling Attributes** (you can also right-click the element in the *breadcrumb* or ***Outline*** view), and select the appropriate values in the **Edit Profiling Attributes** dialog box. You can also use the ***Attributes*** *view* to set the profiling attributes on the element at the current cursor position.

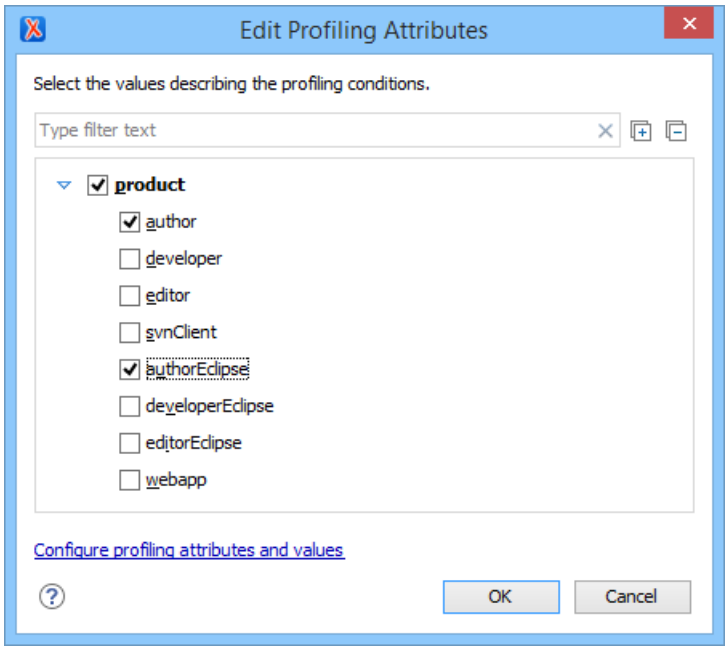

Figure 897: Edit Profiling Attributes Dialog Box

The profiling attributes, and their potential values, that appear in this dialog box depend on what has been configured in Oxygen XML Editor. If you have a large list of profiling attributes, you can use the text filter field to search for attributes or values, and you can expand or collapse attributes by using the **Expand All**/**Collapse All** buttons to the right of the text filter or the arrow button to the left of the profiling attribute name.

The attributes and values that appear in the dialog box are determined as follows:

- If your *root map* references a DITA *subject scheme map* that *defines values for the profiling attributes*, those values are used. Oxygen XML Editor collects all the profiling values from the *subject scheme map* that is referenced in the map that is currently opened in the ***DITA Maps Manager*** (or *set as the root map*). In the *image above* (taken from the Oxygen XML Editor documentation project), you see values for eight products. They are the only values that are defined in the *subject scheme map* and thus, are the only ones that appear in the dialog box.
- If you have *defined profiling attribute values* for the DITA document type in the ***Profiling/Conditional Text preferences page*** and you store them at *project-level*, those values are displayed in the dialog box.
- If you have *defined profiling attribute values* for the DITA document type in the ***Profiling/Conditional Text preferences page*** and you store them at *global-level*, those values are displayed in the dialog box.
- Otherwise, a generic default set of profiling attributes and values are available.

If the ***Show Profiling Attributes*** *option* (available in the **Profiling / Conditional Text** toolbar menu) is selected, a green border is painted around profiled text in the **Author** mode and all profiling attributes set on the current element are listed at the end of the highlighted block. To edit the attributes of a profiled fragment, click one of the listed attribute values. A form control pops up and allows you to add or remove attribute values.

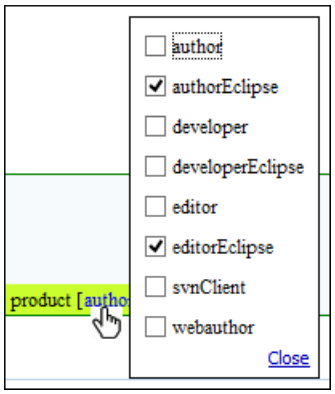

Figure 898: Profiling Attribute Value Form Control Pop Up

Creating and Editing Profiling Condition Sets in DITA

In DITA, profiling conditions can be set both within topics and in maps. When set in a topic, they allow you to suppress an element (such as paragraph), step in a procedure, item in a list, or even a phrase within a sentence. When set in a map, they allow you to suppress an entire topic or group of topics.

Creating Profiling Condition Sets

To create a new profiling condition set, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Editor** > **Edit modes** > **Author** > **Profiling/Conditional Text**.
2. In the ***Profiling Condition Sets** section*, press the **New** button.

   Step Result: The **Condition Set** configuration dialog box is opened.

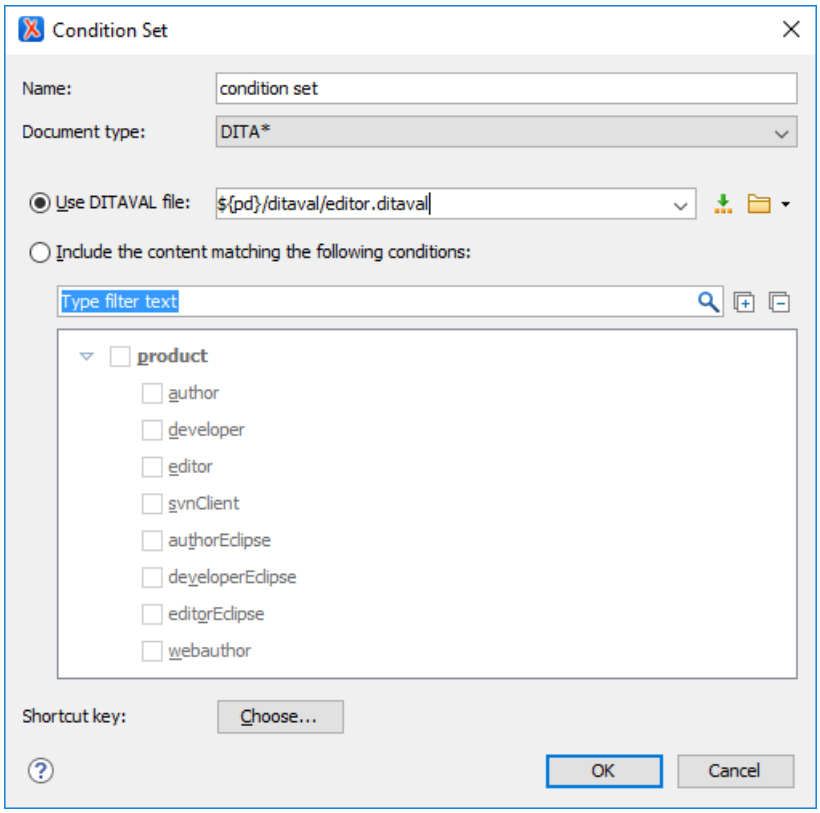

Figure 899: Condition Set Dialog Box

3. Configure your condition set as desired. The following options are available in this dialog box:

   Name

   The name of the new condition set.

   Document type

   Select the document type (*framework*) for which you have defined profiling attributes.

   Use DITAVAL file

   Select this option if you want the *Profiling Condition Set* to reference a *DITAVAL file*. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list.

   Include the content matching the following conditions

   You can select this option to define the combination of attribute values for your condition set by selecting the appropriate checkboxes for the values you want to be included in this particular condition set. If you have defined a lot of profiling attributes, you can use the **filter** text field to search for specific conditions.

   Shortcut key

   You can click the **Choose** button to open a dialog box that allows you to define a shortcut key for this particular condition set. You can then use that shortcut key anytime you want to select this condition set to filter content.

4. Click **OK** to confirm your selections and close the **Condition Set** configuration dialog box.
5. Click **Apply** to save the condition set. All saved profiling condition sets are available in the ***Profiling / Conditional Text*** *toolbar drop-down menu*.

Editing Existing Profiling Condition Sets

To modify an existing profiling condition set, follow these steps:

1. *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to **Editor** > **Edit modes** > **Author** > **Profiling/ Conditional Text**.

2. In the ***Profiling Condition Sets*** *section*, the **Edit** button to modify an existing condition set (you can also use **Delete** button to remove a condition set or the **Up** and **Down** buttons to change their priority).

   Step Result: If you use the **Edit** button, the **Condition Set** configuration dialog box is opened:
3. Modify your condition set as desired.
4. Click **OK** to confirm your selections and close the **Condition Set** configuration dialog box.
5. Click **Apply** to save your modifications.

Sharing Condition Set Configurations

Your condition set configuration can be shared with other users through a project file. If you select ***Project Options*** at the bottom of the **Profiling/Conditional Text** preferences page, your configuration is stored in the project file and can be shared with others. For instance, if your project file is saved on a version control system (such as SVN, CVS, or Source Safe) or in a shared folder, your team will have the same option configuration that you stored in the project file.

For more information about sharing project files, see *Sharing a Project - Team Collaboration* on page 464.

Related Information:

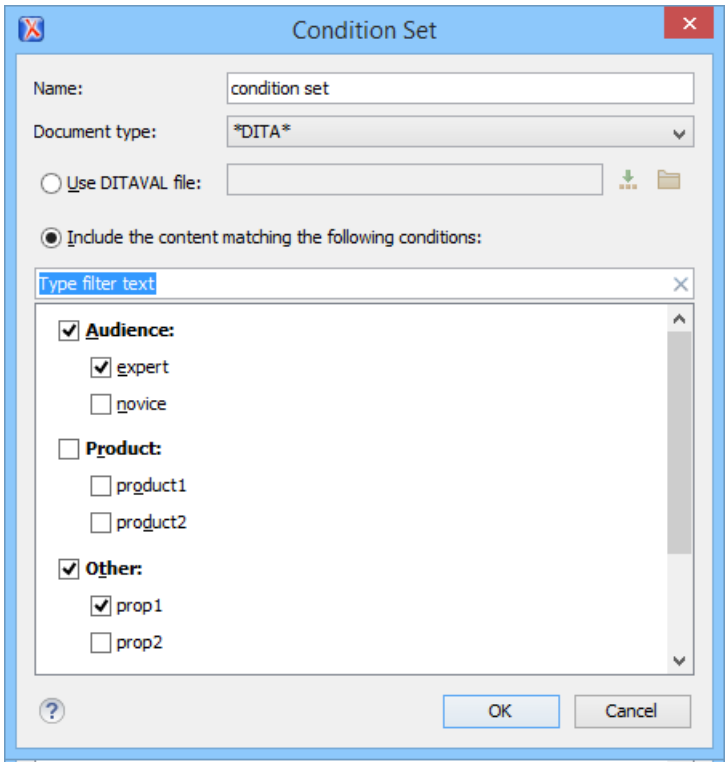
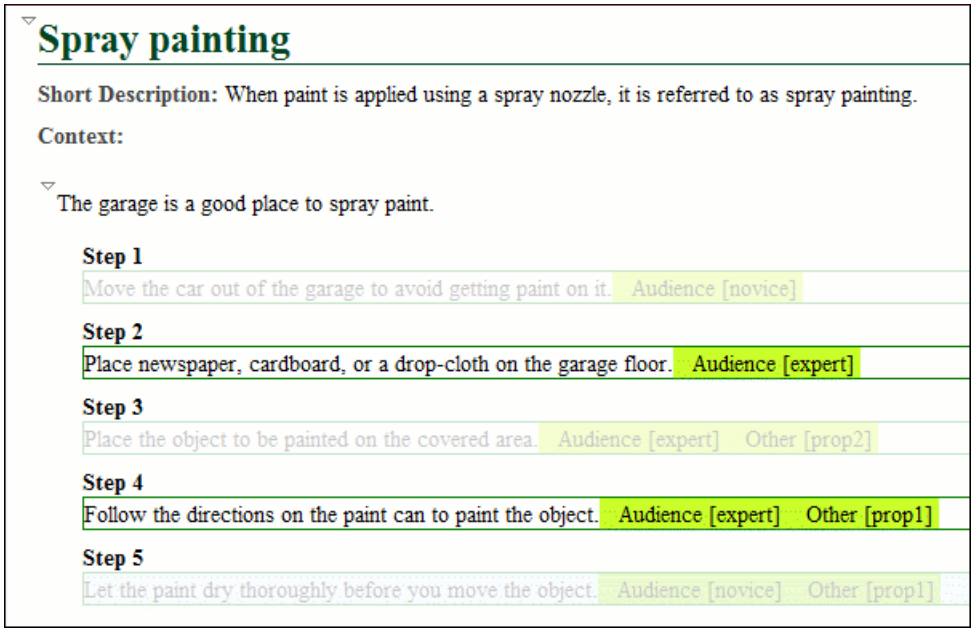
Creating and Editing Profiling Attributes in DITA on page 1907
Applying Profiling Attributes in DITA on page 1908
Showing and Filtering Profiled Content in DITA on page 1914
Customizing Colors and Styles for Rendering Profiling in Author Mode on page 1916

Applying Profiling Condition Sets in DITA



All defined *Profiling Condition Sets* are available as shortcuts in the ***Profiling / Conditional Text*** *toolbar menu*. Select a menu entry to apply the condition set. The filtered content is then grayed-out in the **Author** mode, ***Outline*** *view*, and ***DITA Maps Manager*** *view* (for DITA documents). Your selection will also be used as the *default condition set* in transformation scenarios. An element is filtered-out when one of its attributes is part of the condition set and its value does not match any of the value covered by the condition set.

EXAMPLE:



Suppose that you have the following document:

If you apply the following condition set, it means that you want to filter out the content to only include content written for an expert audience and content that has the *Other* attribute value of *prop1*.

This is how the document looks after you apply the condition set:

Customizing Colors and Styles for Rendering Profiling in Author Mode on page 1916

Showing and Filtering Profiled Content in DITA

You can visualize the effect of profiling content by using the profiling tools in the **Profiling/Conditional Text** drop-down menu that is located on the ***DITA Maps Manager*** toolbar and on the main toolbar. This drop-down menu includes the following filtering options:

Show Profiling Colors and Styles

Select this option to show colors and styles for profiled content in **Author** mode and the ***DITA Maps Manager***. You can configure the colors and styles or specify whether or not this option is selected by default in the ***Profiling/Conditional Text*** > ***Colors and Styles*** *preferences page*.

Show Profiling Attributes

Select this option to display the values of the profiling attributes at the end of profiled content in **Author** mode and next to the nodes in the ***DITA Maps Manager***. You can specify whether or not this option is selected by default in the ***Profiling/Conditional Text*** > ***Attributes Rendering*** *preferences page*.

Show Excluded Content

Controls whether the content filtered out by a particular condition set is hidden or grayed-out in **Author** mode, the ***DITA Maps Manager***, and the ***Outline*** view. When this option is selected and a *condition set is selected in this drop-down menu*, the filtered content is grayed-out. If this option is not selected and a *condition set is selected in this drop-down menu*, the filtered content is hidden. You can specify whether or not this option is selected by default in the ***Profiling/Conditional Text*** *preferences page*.

Choose Condition Set (Available if more than 15 condition sets are defined)

This option is available if you have more than 15 conditions sets defined. It opens a dialog box that makes it easier to find and select condition sets that are not displayed in this drop-down menu.

List of Defined Condition Sets

Up to 15 defined condition sets are listed and you can toggle each one of them on to filter the content in **Author** mode and the ***DITA Maps Manager*** to only show content that will appear in the output for that particular condition set. If there are more than 15 defined condition sets, the rest of them can be accessed in the **More** submenu or by using the ***Choose Condition Set*** *option* to access a dialog box that presents all of them.

Profiling Settings

Opens the ***Profiling/Conditional Text*** *preferences page* where you can add and edit profiling attributes and condition sets.

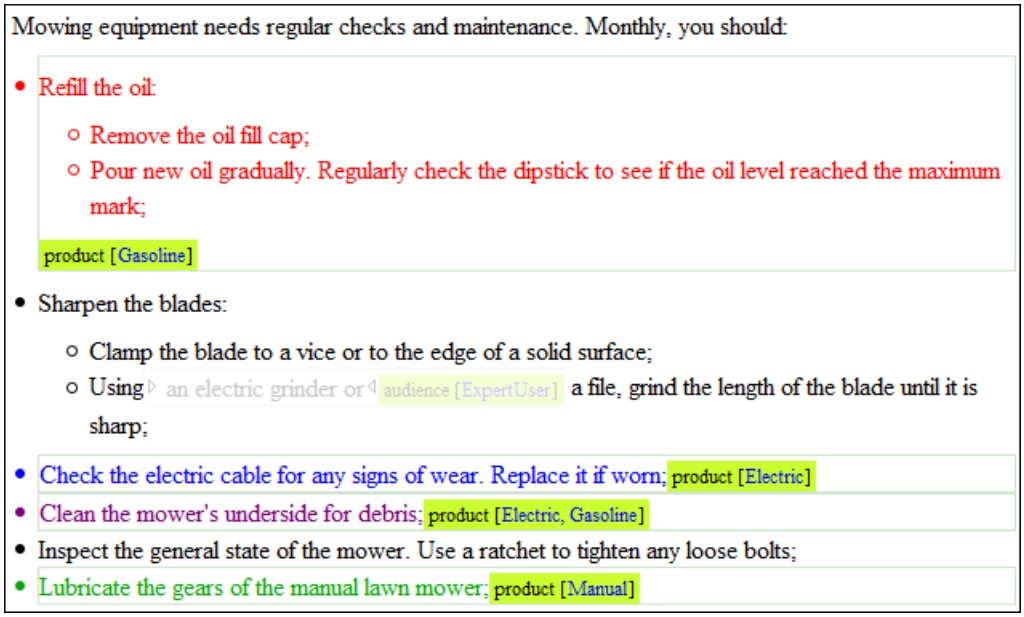

Figure 900: Example: Profiling Controls in Author Mode

If the ***Show Profiling Attributes*** *option* is selected, a green border is painted around profiled text in the **Author** mode. Also, all profiling attributes set on the current element are listed at the end of the highlighted block and in

its tooltip message. To edit the attributes of a profiled fragment, click one of the listed attribute values. A form control pops up and allows you to add or remove attribute values.

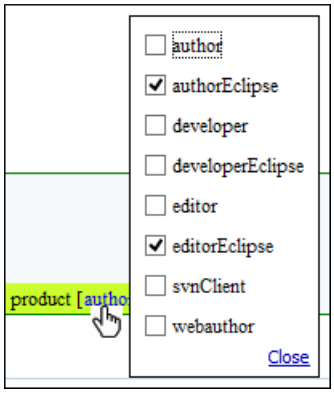

Figure 901: Profiling Attribute Value Form Control Pop Up

Also, the following icons are used to mark profiled and non-profiled topics in the **DITA Maps Manager**:

- - The topic contains profiling attributes.
- - The topic inherits profiling attribute from its ancestors.
- - The topic contains and inherits profiling attributes.
- - (dash) - The topic neither contains, nor inherits profiling attributes.

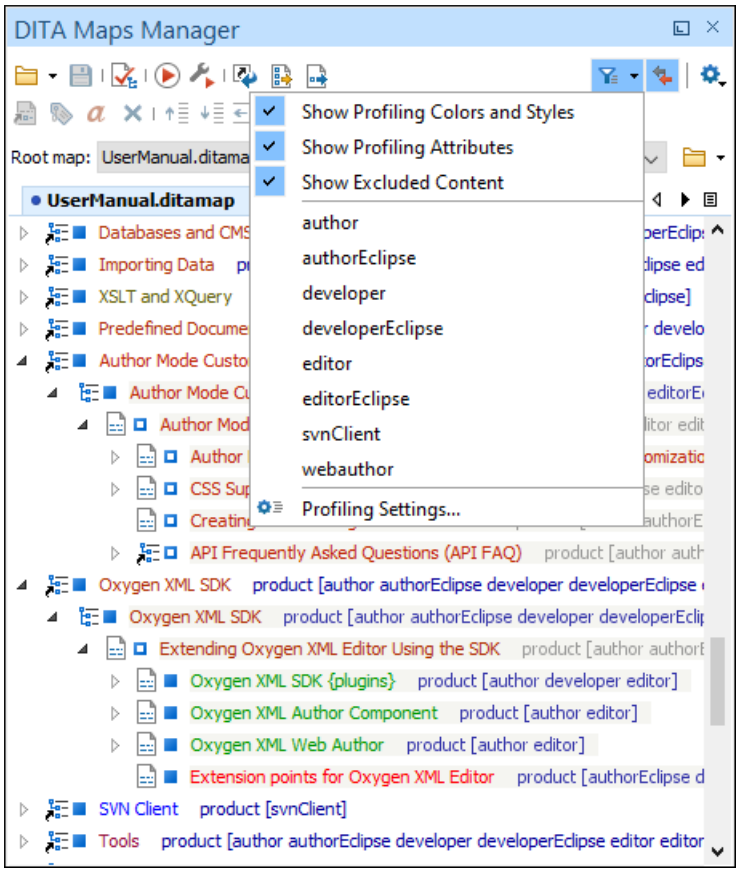

Figure 902: Rendering Profiled Topics in DITA Maps Manager

Related Information:

Creating and Editing Profiling Condition Sets in DITA on page 1910
Applying Profiling Attributes in DITA on page 1908

Applying Profiling Condition Sets in DITA on page 1912

Customizing Colors and Styles for Rendering Profiling in Author Mode on page 1916

Customizing Colors and Styles for Rendering Profiling in Author Mode

By applying profiling colors and styles, you can mark profiled content in **Author** mode and the ***DITA Maps Manager*** so that you can instantly spot differences between multiple variants of the output. This allows you to preview the content that will go into the published output. The excluded text is grayed-out or hidden in **Author** mode and excluded nodes are grayed-out or hidden in the ***DITA Maps Manager***.

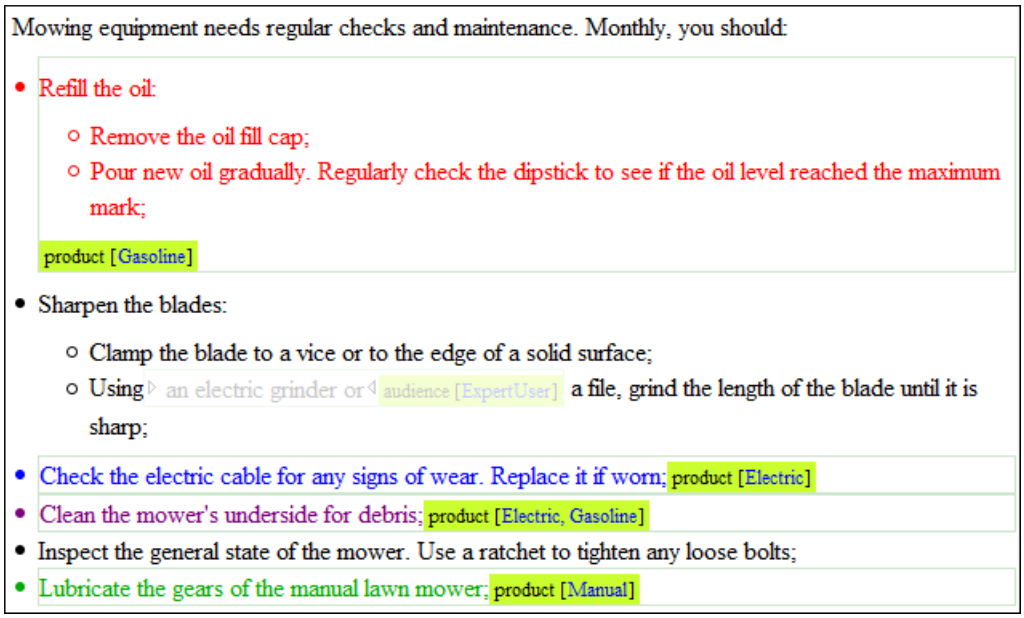

Figure 903: Example: Profiling Colors and Styles in Author Mode

Choosing the right style for a specific profiling attribute is a matter of personal taste, but be aware of the following:

- If the same block of text is profiled with two or more profiling attributes, their associated styles combine. Depending on the styling, this might result in an excessively styled content that may prove difficult to read or work with.
- It is recommended that you only profile the differences. There is no need to profile common content, since excessive profiling can visually pollute the document.
- A mnemonic associated with a style will help you instantly spot differences in the types of content.

Styling Profiling Attribute Values

To set colors and styles for profiling attribute values, follow these steps:

1. Select the ***Show Profiling Colors and Styles*** *option* from the **Profiling / Conditional Text** toolbar drop-down menu.
2. Select ***Profiling Settings*** from the **Profiling / Conditional Text** toolbar drop-down menu. This is a shortcut to the ***Profiling/Conditional Text*** *preferences page*.
3. Go to the ***Colors and Styles*** *preferences page* to configure the colors and styling for the profiling attributes.
4. Go to the ***Attributes Rendering*** *preferences page* to configure how you want the profiling attributes to appear in Oxygen XML Editor.

Result: The styling is now applied in the **Author** editing mode, the ***Outline*** *view*, and in the ***DITA Maps Manager*** *view*. Also, to help you more easily identify the profiling you want to apply in the current context, the styling is applied in the ***Edit Profiling Attributes*** *dialog box* and in the inline form control pop up that allows you to quickly set the profiling attributes.

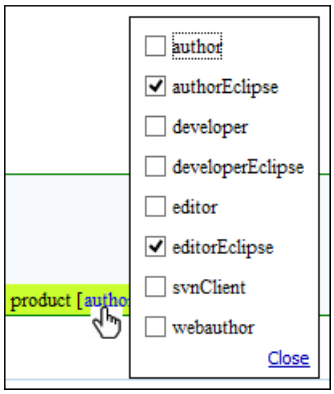

Figure 904: Profiling Attribute Value Form Control Pop Up

Alternate Method with a DITAVAL File: If you are using a DITAVAL filter file to control the filtering of profiled content in DITA topics, you can use a flag filter to define the colors and styles that will be used when rendering the profiling. For detailed information about this alternate method, see the procedure in the *Styling the Rendering of Profiled Content Using a DITAVAL File* on page 1922 topic.

Customizing Profiling Values with a Subject Scheme Map

A *subject scheme map* allows you to create and manage custom profiling values in DITA documents without having to write a DITA specialization. Ultimately, this allows you to filter and flag content in **Author** mode or in transformed output.

Advantages of Using a Subject Scheme Map

The advantages of using a subject scheme to control profiling attribute values include:

- You can create a hierarchy of profiling attribute values and use a DITAVAL file to filter or flag the tree of values.
- You can share the subject scheme files with others without having to share preferences or the entire project.
- The subject scheme offers validation support so you are notified if an undefined value is used.

Overview

Subject scheme maps use key definitions to define a collection of profiling values. You can also use *subject scheme maps* to filter out (reject) the values for certain attributes so that you only see the attributes or values that you want to use in **Author** mode or the transformed output.

The highest level of map (*main DITA map*) that uses the set of profiling values must reference the *subject scheme map* where the profiling values are defined and the `type` attribute needs to be set to `subjectScheme` for the reference, as in the following example:

```
<topicref href="test.ditamap" format="ditamap" type="subjectScheme"/>
```

Creating a Subject Scheme Map

To create and configure a *subject scheme map*, follow this procedure:

1. Use the ***New Document*** *wizard* to create a new **Subject Scheme** document (**Framework templates** > **DITA Map** > **map** > **Subject Scheme**).

2. Use the controls in **Author** mode to define the hierarchical tree of values for your *subject scheme* (*see the Author mode example below*) or switch to **Text** mode and define it there if you prefer (*see the Text mode example below*).

   Note: The pre-defined subject scheme template includes Navigation Titles (`navtitle` element). This element is not required, but if you use it, the text that you enter for the `navtitle` will be used (instead of the name of the value) in the various places where *profiling attributes are presented in Oxygen XML Editor*. An example of when this might be helpful is if you want to use abbreviations for the name of a value, but you want to see its full name in Oxygen XML Editor.
3. Bind the particular attribute to the key you define for the tree of values. Notice that in the *examples below*, the `audience` attribute is bound to the `audienceKey` value.
4. If you want to filter out (reject) values for certain attributes, bind the attributes to a blank value (as you see for the `props` and `otherprops` attributes in the *examples below*). This means that those attributes will not appear in the various places where *profiling attributes are presented in Oxygen XML Editor*.
5. Save your *subject scheme* file.
6. Reference your *subject scheme* in the highest level of map (*main DITA map*) that will use the set of profiling values and set its type to `subjectScheme`. The easiest way to do this is:
   a. With your *subject scheme* file opened in the editor, go to the **DITA Maps Manager** view, right-click the *main DITA map*, and select **Append Child** > **Reference to the currently edited file**.
   b. In the **Insert Topic Reference** dialog box, go to the **Attributes** tab and in the **Type** field, enter or select **subjectScheme**.
   c. Click the **Insert and Close** button and save your main DITA map.

Using a Subject Scheme in Conjunction with a DITAVAL File

You can use a subject scheme to customize a hierarchy of profiling attribute values and then use it in conjunction with a *DITAVAL file to filter or flag* the entire tree of values. For example, suppose one of the values for the `audience` attribute in a hierarchical subject scheme is `surgeon` and it has two subordinate values of `neuro-surgeon` and `plastic-surgeon` (see the *examples below*). You could create a DITAVAL file with the following content:

```
<val>
     <prop action="exclude" att="audience" val="surgeon"/>
</val>
```

That DITAVAL file could then be used for a *condition set* to filter content in **Author** mode or during the transformation stage to *filter content in the output* and the `neuro-surgeon` and `plastic-surgeon` values would be excluded by the filter since the subject scheme defines them as subordinate values of the `surgeon` value.

Example: Subject Scheme Map that Defines Custom Values for the Audience Attribute

This example uses typical audience values for medical personnel (`therapist`, `oncologist`, `physicist`, `radiologist`, `surgeon`, and so on). The `audience` attribute is bound to the `audienceKey` value (which defines the tree of values). You can also see that it filters out all possible values for other attributes (`props` and `otherprops`) so that they won't be available in the various places where *profiling attributes are presented in Oxygen XML Editor*.

Example using Author mode controls:

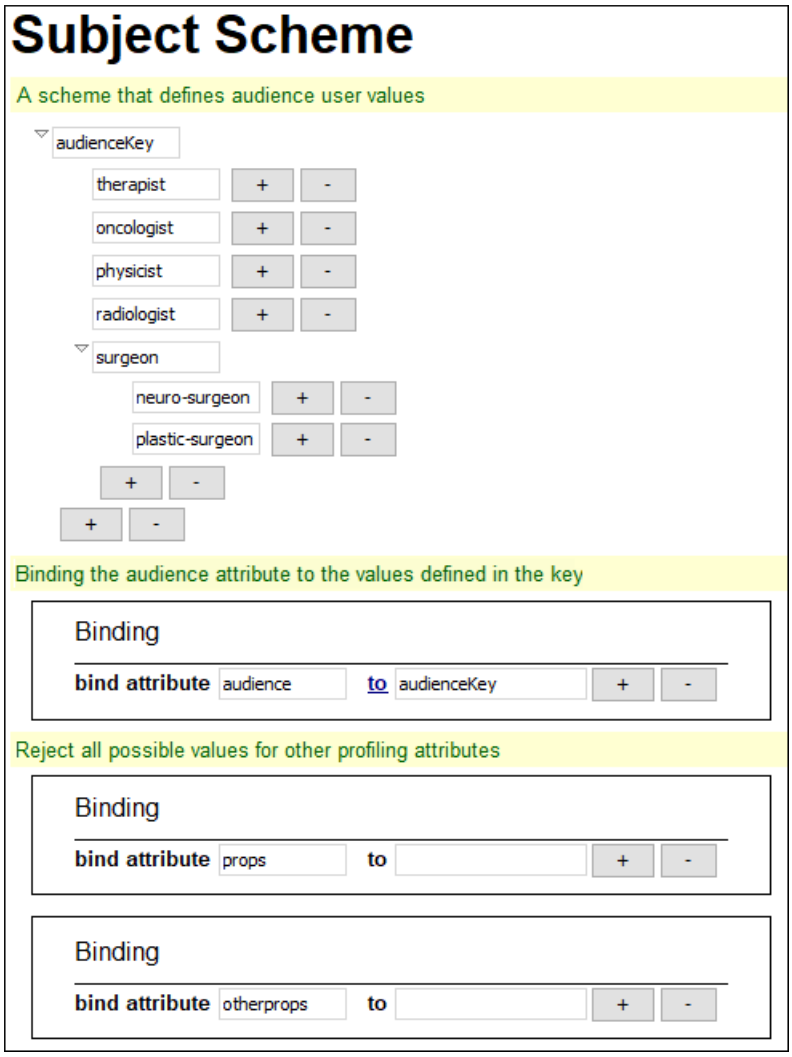

Figure 905: Subject Scheme Author Mode Controls

Example code in Text mode:

```
<subjectScheme>
  <!-- A scheme that defines audience user values -->
  <subjectdef keys="audienceKey">
    <subjectdef keys="therapist"/>
    <subjectdef keys="oncologist"/>
    <subjectdef keys="physicist"/>
    <subjectdef keys="radiologist"/>
    <subjectdef keys="surgeon">
      <subjectdef keys="neuro-surgeon"/>
      <subjectdef keys="plastic-surgeon"/>
    </subjectdef>
  </subjectdef>
  <!-- Binding the audience attribute to the values defined in the key -->
  <enumerationdef>
    <attributedef name="audience"/>
    <subjectdef keyref="audienceKey"/>
  </enumerationdef>

  <!--Reject all possible values for other profiling attributes-->
  <enumerationdef>
    <attributedef name="props"/>
    <subjectdef/>
  </enumerationdef>
  <enumerationdef>
    <attributedef name="otherprops"/>
    <subjectdef/>
  </enumerationdef>
</subjectScheme>
```

Where the Profiling Attributes are Available in Oxygen XML Editor

When you edit a DITA topic in the **Text** or **Author** mode, Oxygen XML Editor collects all the profiling values from the *subject scheme map* that is referenced in the map that is currently opened in the ***DITA Maps Manager*** (or set as the *root map*). The values of profiling attributes defined in a *Subject Scheme Map* are available in the following places in Oxygen XML Editor (regardless of their mapping in the ***Profiling/Conditional Text*** *preferences page*):

- The ***Profiling*** *tab of the* ***Edit Properties*** *dialog box*.
- The ***Edit Profiling Attribute*** *dialog box*.
- The *inline profiling controls in* ***Author*** *mode*.
- The proposals for the attribute values in the *Content Completion Assistant*.

More Details

For more details about hierarchical filtering, defining controlled values, and using *subject scheme maps*, refer to the following resources:

- *DITA 1.3 Specifications: Subject Scheme Maps*
- *Oxygen Video Tutorial: DITA Subject Scheme*

Filtering Profiling Values with a DITAVAL File on page 1920

Filtering Profiling Values with a DITAVAL File

You can use a DITAVAL filter file to control the filtering or flagging of profiled content or to identify which values are to be used for conditional processing during a particular output.

DITAVAL Filtering Use-Case

Suppose that a medical publication uses the `audience` attribute to profile the content for the following types of users: *therapist*, *physician*, and *surgeon*. Suppose that in the output, you want to exclude any content that is profiled as `surgeon` value for the `audience` attribute.

You could use a DITAVAL filter file to exclude anything that is profiled as `surgeon`:

```
<val>
     <prop action="exclude" att="audience" val="surgeon"/>
</val>
```

If you then transform the main *DITA map* and specify the DITAVAL filter file in the transformation scenario, the output will exclude anything that is profiled as `surgeon`).

DITAVAL Filter File Editor in Author Mode

The **Author** editing mode in Oxygen XML Editor offer a simple and intuitive editor for creating or modifying DITAVAL files. It provides a series of drop-down menus and text fields that allow you to easily define the filters.

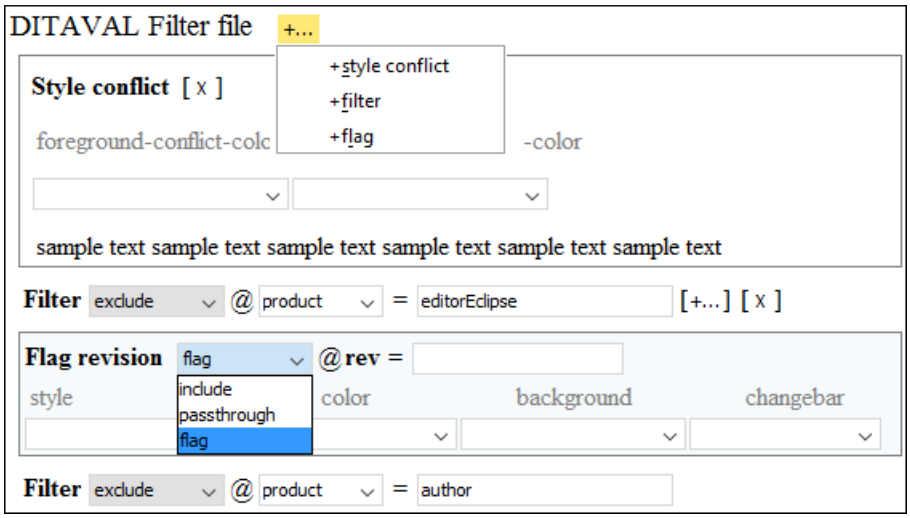

Figure 906: DITAVAL File Editor in Author Mode

Use the **+...** button to display a drop-down list that contains elements that you can add at that particular location in the DITAVAL file. Clicking this button at the top (next to the **DITAVAL FILTER File** title, allows you to insert the following elements:

- **Style Conflict** - Inserts a *style-conflict element* that declares behavior to be used when one or more flagging methods collide on a single content element. You can use the simple drop-down menus to select values for the `foreground-conflict-color` and `background-conflict-color` attributes.
- **Filter** - Inserts a *prop element* that identifies an attribute to apply a filtering action on. The possible actions that you can select are *include*, *exclude*, *passthrough*, and *flag*. If you select the *flag* action, you can use the drop-down menus to select values for the `style`, `color`, and `background` attributes.
- **Flag** - Inserts a *revprop element* that Identifies a value in the `rev` attribute that should be flagged in some manner. The allows actions are *include*, *passthrough*, and *flag*. If you select the *flag* action, you can use the drop-down menus to select values for the `style`, `color`, `background`, and `changebar` attributes.

See the *DITAVAL Element Specifications* for more details about the allowed filters and flags.

How to Create a DITAVAL Filter File

To create a DITAVAL filter file, follow these steps:

1. Go to **File** > **New**.
2. Scroll to the **Framework templates** > **DITAVAL** folder.
3. Select the **Filter** template file and click **Create**.
4. Define your filters in the DITAVAL file (in **Text** or **Author** mode).
5. Save the DITAVAL file.

Result: The DITAVAL filter file can now be used for all of the following:

- To apply a reference to the DITAVAL file in a *Profiling Condition Set* using the ***Use DITAVAL File*** *option* in the ***Condition Set*** *configuration dialog box*.
- You can use the ***Import from DITAVAL*** *option* in the ***Profiling/Conditional Text*** *preferences page* to use the DITAVAL file to define profiling attributes.
- You can use the DITAVAL file to apply the filters to the output by specifying the *DITAVAL file in the transformation scenario*.
- You can use the filter file in the ***DITA Map Completeness Check*** *dialog box* when validating your *DITA map*.
- DITAVAL files are also used when working with the DITA 1.3 *Branch Filtering* mechanism. For more details, see: *Working with DITA 1.3 Branch Filtering* on page 1875.
- You can *define the colors and styles to be used for rendering profiled condition sets* in **Author** mode and the ***DITA Maps Manager*** view by using a **Flag** filter in the DITAVAL file.

Related Information:

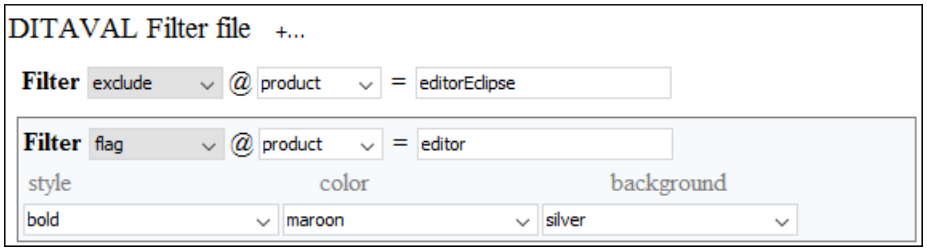
DITAVAL Element Specifications

Working with DITA 1.3 Branch Filtering on page 1875
Customizing Profiling Values with a Subject Scheme Map on page 1917
Styling the Rendering of Profiled Content Using a DITAVAL File on page 1922

Styling the Rendering of Profiled Content Using a DITAVAL File

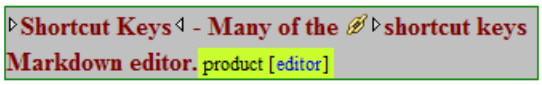
If you are using a DITAVAL filter file to control the filtering of profiled content, you can define the colors and styles to be used for rendering profiled condition sets in **Author** mode and the ***DITA Maps Manager*** by defining the styles in a flag filter that is set in a DITAVAL filter file.

How to Define a Flag for a Condition Set in a DITAVAL Filter File



To define the colors and styles to be used for rendering profiled condition sets by using a flag filter in a DITAVAL filter file, follow these steps:

1. *Create or edit your DITAVAL file* to define your *profiling condition set*.
2. In **Author** mode, *define the filters for your condition set*.
3. Select **Flag** from the drop-down menu on in a particular **Filter** or **Flag Revision** to present additional drop-down menus that allow you to configure the colors and styles for the particular condition set.
4. Save the DITAVAL file.



Result: Test your changes by opening profiled content in **Author** mode or the ***DITA Maps Manager*** and use the options in the **Profiling / Conditional Text** drop-down menu to see how the changes in your DITAVAL flag are rendered.

EXAMPLE:

Using a **Flag** on a **Filter** to define the styling for a condition set like this:

will render the styling of the profiled content in **Author** mode to look like this:

and will render the styling in the ***DITA Maps Manager*** *view* to look like this:

Filtering Profiling Values with a DITAVAL File on page 1920

Publishing Profiled DITA Content

You can create a variety of publications or versions of your documentation from a single map by applying profiling conditions to the build.

Oxygen XML Editor includes preconfigured transformation scenarios for DITA. By default, these scenarios take the current *profiling condition set* into account during the transformation, as defined in the ***Filters** tab* when *creating a DITA transformation*. You can also specify a *DITAVAL file* that defines filters for your profiled content.

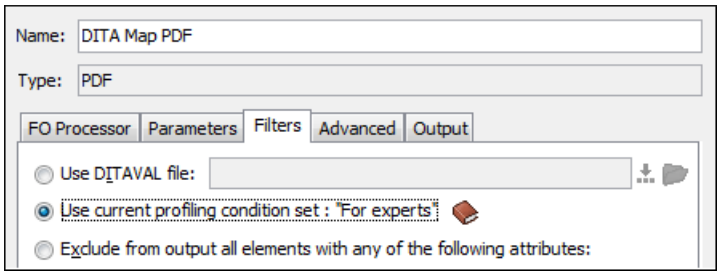

Figure 907: Profiling Option in the Filters Tab (DITA OT Transformations)

DITA Open Toolkit Support

Oxygen XML Editor includes support for the DITA Open Toolkit. This section includes information about how to create a DITA OT *plugin*, how to install *plugins* in the DITA OT, and how to use an external instance of the DITA Open Toolkit.

Related Information:

DITA Open Toolkit Documentation

Creating a DITA OT Customization Plugin

To describe the steps involved in creating a **DITA Open Toolkit** *plugin*, this section uses an example of creating an **XSLT** customization *plugin* that provides syntax highlighting when publishing DITA `codeblock` elements to **HTML** and **PDF** output formats. This *plugin* (**com.oxygenxml.highlight**) that provides syntax highlighting is available in the **DITA Open Toolkit** distribution that comes bundled with the latest version of Oxygen XML Editor, but these instructions show you how to create it as if it were not included.

The steps to help you to create the *plugin* are as follows:

1. Create a folder for your *plugin* in the DITA OT **plugins** folder (*DITA-OT-DIR*`/plugins/`).

   For example, if you are using DITA 1.8.5, the path would look like this:

   [OXYGEN_INSTALL_DIR]`/frameworks/dita/DITA-OT/plugins/com.oxygenxml.highlight`
2. Create a **plugin.xml** file (in the same *plugin* folder) that contains the extension points of the *plugin*.

   Note: You can easily create this file by using the **DITA OT Plugin** new file template that is included in Oxygen XML Editor. From the **New** file wizard you can find this template in **Framework templates** > **DITA** > **plugin**.

   For example, our syntax highlighting plugin example contains the following:

   ```
   <plugin id="com.oxygenxml.highlight">
     <feature extension="package.support.name" value="Oxygen XML Editor Support"/>
     <feature extension="package.support.email" value="support@oxygenxml.com"/>
     <feature extension="package.version" value="1.0.0"/>
     <feature extension="dita.xsl.xhtml" value="xhtmlHighlight.xsl" type="file"/>
     <feature extension="dita.xsl.xslfo" value="pdfHighlight.xsl" type="file"/>
   </plugin>
   ```

   The most important extensions in it are the references to the XSLT stylesheets that will be used to style the HTML and PDF outputs.

   You can find other **DITA OT** *plugin* extension points here: *http://dita-ot.sourceforge.net/1.5.3/dev_ref/extension-points.html*
3. Create an XSLT stylesheet to customize the output types. In our example, to customize the HTML output we need to create an XSLT stylesheet called **xhtmlHighlight.xsl** (in the same *plugin* folder).

   Tip: You can use the ***Find/Replace in Files** action* to find an XSLT stylesheet with content that is similar to the desired output and use it as a template to overwrite parts of your stylesheet. In our example we want to overwrite the creation of the HTML content from a DITA **codeblock** element. Since a DITA `codeblock`

element has the `class` attribute value `+ topic/pre pr-d/codeblock` we can take part of the class attribute value (**topic/pre**) and search the **DITA OT** resources for a similar stylesheet.

Our search found the XSLT stylesheet *DITA-OT-DIR*`/org.dita.xhtml/xsl/xslhtml/dita2htmlImpl.xsl` that contains:

```
<xsl:template match="*[contains(@class,' topic/pre ')]" name="topic.pre">
  <xsl:apply-templates select="."  mode="pre-fmt" />
</xsl:template>
```

We use it to overwrite our **xhtmlHighlight.xsl** stylesheet, which results in the following:

```
<xsl:template match="*[contains(@class,' topic/pre ')]" name="topic.pre">
    <!-- This template is deprecated in DITA-OT 1.7.
         Processing will moved into the main element rule. -->
    <xsl:if test="contains(@frame,'top')"><hr /></xsl:if>
    <xsl:apply-templates select="*[contains(@class,' ditaot-d/ditaval-startprop ')]"
          mode="out-of-line"/>
    <xsl:call-template name="spec-title-nospace"/>
    <pre>
      <xsl:attribute name="class"><xsl:value-of select="name()"/></xsl:attribute>
      <xsl:call-template name="commonattributes"/>
      <xsl:call-template name="setscale"/>
      <xsl:call-template name="setidaname"/>
     <!--Here I'm calling the styler of the content inside the codeblock.-->
     <xsl:call-template name="outputStyling"/>
    </pre>
    <xsl:apply-templates select="*[contains(@class,' ditaot-d/ditaval-endprop ')]"
          mode="out-of-line"/>
    <xsl:if test="contains(@frame,'bot')"><hr /></xsl:if><xsl:value-of select="$newline"/>
  </xsl:template>
```

You could also use another XSLT template that applies the XSLTHL library as a Java extension to style the content.

4. Create additional XSLT stylesheets to customize all other desired output types. In our example, to customize the PDF output we need to create an XSLT stylesheet called **pdfHighlight.xsl** (in the same *plugin* folder).

   In this case we found an appropriate XSLT stylesheet *DITA-OT-DIR*`/plugins/legacypdf/xslfo/dita2fo-elems.xsl` to use as a template that we use to overwrite our **pdfHighlight.xsl** stylesheet, which results in the following:

   ```
   <xsl:template match="*[contains(@class,' topic/pre ')]">
     <xsl:call-template name="gen-att-label"/>
     <fo:block xsl:use-attribute-sets="pre">
       <!-- setclass -->
       <!-- set id -->
       <xsl:call-template name="setscale"/>
       <xsl:call-template name="setframe"/>
       <xsl:apply-templates/>
     </fo:block>
   </xsl:template>
   ```

   Note: You can edit the newly created stylesheets to customize multiple outputs in a variety of ways. For example, in our case you could edit the **xhtmlHighlight.xsl** or **pdfHighlight.xsl** stylesheets that we created to customize various colors for syntax highlighting.

5. To install the created *plugin* in the **DITA OT**, run the predefined transformation scenario called **Run DITA OT Integrator** by executing it from the ***Apply Transformation Scenario(s)*** *dialog box*. If the integrator is not visible, select the **Show all scenarios** option that is available in the **Settings** drop-down menu. For more information, see *Installing a Plugin in the DITA Open Toolkit*.

   Results of running the integrator using our example:

   XSLT content is applied with priority when publishing to both HTML and PDF outputs.

   a. For the HTML output, in the XSLT stylesheet *DITA-OT-DIR*`/xsl/dita2html-base.xsl` a new import automatically appeared:

      ```
      <xsl:import href="../plugins/com.oxygenxml.highlight/xhtmlHighlight.xsl"/>
      ```

      This import is placed after all base imports and thus has a higher priority. For more information about imported template precedence, see: *http://www.w3.org/TR/xslt#import*.

b. Likewise, for the PDF output, in the top-level stylesheet *DITA-OT-DIR*`/plugins/org.dita.pdf2/xsl/fo/topic2fo_shell_fop.xsl` a new import statement appeared:

```
<xsl:import href="../../../com.oxygenxml.highlight/pdfHighlight.xsl"/>
```

Now, you can distribute your *plugin* folder to anyone that has a DITA OT installation along with some simple installation notes. Your customization will work provided that the templates you are overwriting have not changed from one DITA OT distribution to the other.

Related Information:

DITA Open Toolkit Documentation

Installing a Plugin in the DITA Open Toolkit

The architecture of the **DITA Open Toolkit** allows additional *plugins* to be installed.

1. The additional *plugins* should be copied to the *DITA-OT-DIR*`\plugins` directory.

   Note: If the *plugin* is only supported in DITA-OT 2.5.2 version, make sure that you copy the *plugin* in the *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/DITA-OT2.x` directory.
2. Run the predefined transformation scenario called **Run DITA OT Integrator** by executing it from the ***Apply Transformation Scenario(s)** dialog box*. If the integrator is not visible, select the **Show all scenarios** option that is available in the **Settings** drop-down menu.

   Important: The folder where the **DITA OT** is located needs to have full write access permissions set to it. For example if you are integrating *plugins* in the **DITA OT** folder bundled with Oxygen XML Editor and if you are running on **Windows** and your application is installed in the **Program Files** folder, you can start the Oxygen XML Editor main executable with administrative rights for the integrator process to be able to modify resources in the **DITA OT** folder.

   Starting with version 17.0, Oxygen XML Editor detects the transformation type (`transtype`) declarations from **DITA OT** *plugins* and presents descriptions, which are contributed in the `transtype` declarations, in the **DITA Transformation Type** dialog box. Oxygen XML Editor also shows the contributed parameters from **DITA OT** *plugins* in the **Parameters** tab in the **Edit DITA Scenario** dialog box.
3. If the *plugin* contributed a new transformation type that is not detected (for instance, if you are using a previous version of Oxygen XML Editor that does not detect the `transtype` declarations), you can create a new **DITA OT** transformation scenario with a predefined type that is similar to the new transformation type. Then edit the transformation scenario, and in the **Parameters** tab add a `transtype` parameter with the value of the new transformation type.

Note: A transformation type can also extend another `transtype`. For example, the *pdf-prince* `transtype` extends a `commons` transformation type that contains all the common DITA OT parameters.

Example:

```
<plugin id="com.oxygenxml.pdf.prince">
  <!-- extensions -->
  <feature extension="dita.conductor.transtype.check" value="pdf-prince"
 type="txt"/>
  <feature extension="dita.conductor.target.relative" value="integrator.xml"
 type="file"/>
  <feature extension="dita.transtype.print" value="pdf-prince"/>
  <transtype name="pdf-prince"extends="commons" desc="PDF (Prince XML)">
    <param name="princeExecPath" type="file" desc="Path to the Prince executable
 file that will produce the PDF"/>
  </ Transtype>
</plugin>
```

Installing the DITA For Publishers Package

DITA Open Toolkit Documentation

Use an External DITA Open Toolkit in Oxygen XML Editor

Oxygen XML Editor comes bundled with a DITA Open Toolkit, located in the *DITA-OT-DIR* directory. Starting with Oxygen XML Editor version 17, if you want to use an external DITA OT for all transformations and validations, you can *open the **Preferences** dialog box **(Options > Preferences)*** and go to *the **DITA** page*, where you can specify the DITA OT to be used. Otherwise, to use an external DITA Open Toolkit, follow these steps:

1. Edit your transformation scenarios and in the **Parameters** tab change the value for the **dita.dir** parameter to point to the new directory.
2. To make changes in the libraries that come with the DITA Open Toolkit and are used by the Ant process, go to the **Advanced** tab, click the **Libraries** button and deselect **Allow Oxygen to add high priority libraries to classpath**.
3. If there are also changes in the DTDs and you want to use the new versions for content completion and validation, go to the ***Document Type Association** preferences page*, edit the **DITA** and **DITA Map** document types and modify the catalog entry in the **Catalogs** tab to point to the custom catalog file `catalog-dita.xml`.

DITA Open Toolkit Documentation

Third-Party DITA Open Toolkit Plugins

The DITA Open Toolkit 1.8.5 and 2.5.2 distributions that are bundled with Oxygen XML Editor include some pre-installed third-party open-source *plugins* that add extra publishing formats and functionality.

The *plugins* that come bundled with Oxygen XML Editor include:

- ***DITA For Publishers*** (installed only in DITA OT 1.8.5) - These *plugins* allow DITA content to be published to additional formats, such as EPUB 2.0 and Kindle.
- ***DITA to Reveal JS*** (installed only in DITA OT 1.8.5) - This *plugin* allows users to publish DITA content to web slides that can be used for presentations.
- ***DITA to Word*** (installed only in DITA OT 2.5.2) - This *plugin* allows users to publish DITA content to MS Word.
- ***DITA Markdown*** (installed only in DITA OT 2.5.2) - This *plugin* allows users to publish DITA content to *Markdown*, or to publish *DITA maps* that reference *Markdown* resources.
- ***Lightweight DITA*** (installed only in DITA OT 2.5.2) - This *plugin* allows users to create, edit, and validate *Lightweight* DITA topics and *maps*.
- ***DITA Community*** (installed only in DITA OT 2.5.2) - These *plugins* allow support for DITA 1.3 with embedded or referenced MathML and SVG images.

DITA Specialization Support

DITA is designed to let you design new markup and new document types that allow any general-purpose DITA processor to process documents that use the new markup. This in turn enables blind interchange of DITA documents from any source. In particular, in the context of a map, you can combine topics of any type and get usable results from any general-purpose DITA processor. Specialization is the one truly unique and distinguishing aspect of DITA. Even if you have no use for any aspect of DITA modularity or reuse, you still have a use for specialization simply because it enables reliable interchange in a way that no other XML application does.

For detailed information and step-by-step tutorials about DITA specializations, see *DITA 4 Practitioners: DITA Configuration and Specialization Tutorials*.

In addition, the topics in this section contain information about using DITA specializations in Oxygen XML Editor.

Integrating a DITA Specialization

A DITA specialization usually includes:

- DTD definitions for new elements as extensions of existing DITA elements.

- Optional specialized processing that is new XSLT template rules that match the extension part of the `class` attribute values of the new elements and thus extend the default processing available in the DITA Open Toolkit.

To integrate a DITA specialization into Oxygen XML Editor, use one of these methods:

DITA-OT Plugin Method

If the DITA specialization is available as a DITA Open Toolkit plugin, follow this procedure:

1. Copy the plugin to the location of the DITA OT you are using (by default *DITA-OT-DIR*`\plugins`).

   Important: The application needs to have full write access permissions to the DITA OT directory.
2. If Oxygen XML Editor was installed in the default location, you may need to restart and run it as an administrator.
3. Select the ***Configure Transformation Scenario(s)*** action from the **DITA Maps Manager** toolbar (you could also use the same action on the main toolbar or open the ***Transformation Scenarios*** *view*).
4. Select the **Run DITA OT Integrator** transformation scenario.

   Tip: If you don't see that scenario in the ***Configure Transformation Scenario(s)*** dialog box or ***Transformation Scenarios*** *view*, click the **Settings** button and select the **Show all scenarios** option, but don't forget to change it back to **Show only the scenarios available for the editor** after you are finished with this procedure.
5. *Apply the scenario*.
6. Check the **Results** panel at the bottom of the application to make sure the build was successful.
7. Restart Oxygen XML Editor with your normal permissions.

Tip: Oxygen XML Editor detects *new document templates* contributed by the DITA OT plugin as long as you do the following:

1. Create a new folder called **template_folders** inside the *DITA-OT-DIR*`\plugins` directory.
2. Create one or more subfolders inside the **template_folders** directory that contain the new file templates. The new document templates found in those subfolders will be available in the **New** document wizard.

Alternative Options

If the DITA specialization is not available as a DITA OT plugin, you have the following options:

- If the DTDs that define the extension elements are located in a folder outside the DITA Open Toolkit folder, add new rules to the DITA OT catalog file. These rules are meant for resolving the DTD references from the DITA files that use the specialized elements to that folder. This allows for correct resolution of DTD references to your local DTD files and is needed for both validation and transformation of the *DITA maps* or topics. The DITA OT catalog file is called `catalog-dita.xml` and is located in the root folder of the DITA Open Toolkit.
- If there is specialized processing provided by XSLT stylesheets that override the default stylesheets from DITA OT, these new stylesheets must be called from the DITA OT Ant build scripts.

  Important: If you are using DITA specialization elements in your DITA files, it is recommended that you activate the **Enable DTD/XML Schema processing in document type detection** option in the ***Document Type Association*** *preferences page*.
- You could *create your own document templates*, store them in a custom direction, then add that directory to the list of template directories that Oxygen XML Editor uses by adding the directory to the list in the *Document Templates Preferences* on page 112.

Related Information:

DITA Configuration and Specialization Tutorials

Editing DITA Map Specializations

In addition to recognizing the default *DITA map* formats (`map` and `bookmap`), the ***DITA Maps Manager*** *view* can also be used to open and edit specializations of *DITA maps*.

All advanced edit actions available for the map (such as insertion of topic refs, heads, properties editing) allow you to specify the element in an editable combo box. Moreover the elements that appear initially in the combo are all the elements that are allowed to appear at the insert position for the given specialization.

The topic titles rendered in the ***DITA Maps Manager*** *view* are collected from the target files by matching the `class` attribute and not a specific element name.

When editing DITA specializations of maps in the main editor the insertions of topic reference, topic heading, topic group and conref actions should work without modification. For the table actions, you have to modify each action manually to insert the correct element name at cursor position. You can go to the **DITA Map** document type from the ***Document Type Association*** *preferences page* and edit the table actions to insert the element names as specified in your specialization. See *Adding/Editing a Framework (Document Type)* on page 1392 for more details.

Related Information:

DITA Configuration and Specialization Tutorials

Integrating a DITA Specialization on page 1926

Editing DITA Topic Specializations

In addition to recognizing the default DITA topic formats, topic specializations can also be edited in the **Author** mode.

The content completion should work without additional modifications and you can choose the tags that are allowed at the cursor position.

The CSS styles in which the elements are rendered should also work on the specialized topics without additional modifications.

The toolbar/menu actions should be customized to insert the correct element names. You can go to the `DITA` document type from the ***Document Type Association*** *preferences page* and edit the actions to insert the element names, as specified in your specialization. See *Adding/Editing a Framework (Document Type)* on page 1392 for more details.

DITA Configuration and Specialization Tutorials

Integrating a DITA Specialization on page 1926

Master Files Support in DITA

Oxygen XML Editor includes a feature that allows you to define *Master Files* at project level. This feature is typically used in Oxygen XML Editor for XML documents to determine the context for operations such as validation, content completion, refactoring, searches, or displaying components collected from various modules. For DITA projects, this feature has a more limited purpose in Oxygen XML Editor since it is mainly used to provide the means for updating references to moved or renamed resources.

Since you can move or rename DITA resources (such as topics and maps) in the ***DITA Maps Manager***, the *root map* is used as the scope to update all the references to the moved or renamed resources. However, you do not have this option for non-DITA resources (such as folders, images, html files, audio, video, text files, Markdown documents) since they do not appear in the **DITA Maps Manager**. Also, when moving DITA resources in the **DITA Maps Manager**, you have to do it one at a time.

You can use the *Master Files* support in DITA to update all the references to moved or renamed resources in the scope of the *Master Files*, and since the *root map* will be set as the *Master File*, you achieve the same result as if you were moving or renaming them in the **DITA Maps Manager**. It also allows you to move multiple DITA resources (or entire folders) at once in the ***Project*** *view*, instead of the **DITA Maps Manager**, while still giving you the option of updating all the references.

How to Enable Master Files Support in DITA

To use the *Master Files* support in DITA, follow these steps:

1. Go to the ***Project*** *view* and enable *Master Files* support with one of the following methods:
   - Select **Enable Master Files Support** from the **Settings** menu in the top-right corner.
   - Select **Enable Master Files Support** from the contextual menu of the project root folder. If a disabled *Master Files* folder exists, you can also select that option from its contextual menu.
   - Click the **Enable** button in the tooltip located at the bottom. This tooltip window is displayed when the *Master Files* support is disabled. Clicking the **Read more** link takes you to the user guide. Clicking the **Enable** button opens the **Enable Master Files** dialog box. This dialog box contains general information about the **Master Files Support** and allows you to enable it.

     Warning: Once you close this window tip, Oxygen XML Editor hides it for all projects. You can make the window tip reappear by *resetting Oxygen XML Editor to its default settings*. However, doing so will result in you losing your customized options.
2. Add the *main DITA map (root map)* to the Master Files folder by doing one of the following:
   - Right-click the project root folder and select **Detect Master Files**.
   - Right-click the *Master Files* folder and select **Detect Master Files from Project**.
   - If you enabled the *Master Files* support from the tooltip at the bottom of the **Project** view, you can also use the **Detect and Enable** button in the resulting dialog box to detect the *master files* from the current project.
   - Manually add the *root map* to the *Master Files* folder by doing one of the following:
     - Right-click a file from your project and select **Add to Master Files** from the contextual menu (or simply drag and drop it into the *Master Files* folder).
     - Select **Add Files** or **Add Edited File** from the contextual menu of the *Master Files* folder.

Moving or Renaming Non-DITA Resources and Updating the References to Them

With the *Master Files* support enabled, you can move or rename non-DITA resources (such as folders, images, html files, audio, video, text files, Markdown documents) or move multiple normal DITA resources (or entire folders) in the ***Project*** *view* and Oxygen XML Editor will offer the option of updating all the references to the moved or renamed resources in the scope of the *Master Files* (in this case, the *main DITA map (root map)*).

To move or rename non-DITA resources (or move multiple DITA resources) and update the references to them, follow these steps:

1. Enable *Master Files* support and add your *root DITA map* to the *Master Files* folder as described in the *How to Enable Master Files Support in DITA* on page 1928 section above.
2. Go to the ***Project*** *view*, and use one of the following methods to move or rename the resources:

   Moving Resources

   To move resources in the ***Project*** *view*, do one of the following:

   - Simply drag and drop the resource to the new location in the tree structure (the **Enable drag-and-drop in Project view** option must be selected in the ***View*** *preferences page*).
   - Use the **Cut**, **Copy**, and **Paste** actions from the contextual menu.
   - Right-click the resource and select **Refactoring** > **Move resource** action from the contextual menu. Note that this method also allows you to specify a new name and destination path in the **Move resource** dialog box.

   Result: In all cases, a **Move resource** dialog box will be presented.

   Renaming Resources

   To rename resources in the ***Project*** *view*, do one of the following:

   - Select the resource and press **F2**, or simply left-click again, until the in-place editor allows you to change the title.
   - Right-click the resource and select **Rename** or **Refactoring** > **Rename resource** .

   Result: In all cases, a **Rename resource** dialog box will be presented.

3. Make sure the **Update references of the moved resource(s)** option is selected in the resulting **Move** or **Rename** dialog box and keep the scope as **master files** to make sure all the references to the moved or renamed resource are updated.

Metadata

Metadata is a broad concept that describes data that explains or identifies other data. Metadata can be used for many purposes, from driving automation of document builds to enabling authors and readers to find content more easily. DITA provides numerous types of metadata, each of which is used and created differently. Some of the most important forms of metadata in DITA are topic and taxonomy.

Topic Metadata

Topic metadata describes the topic and what it is about. Topic metadata can be inserted in the `prolog` element of a topic or inside the `topicref` element that points to a topic from a map. In other words, metadata about the topic can be asserted by the topic itself, or can be assigned to it by the map that includes it in the build. This allows multiple maps to assign different metadata to the same topic. This may be appropriate when you want to describe a topic differently in various documents.

Taxonomy and Subject Scheme

A taxonomy is a controlled vocabulary. It can be used to standardize how many things in your content and metadata are named. This consistency in naming can help ensure that automated processes work correctly, and that consistent terminology is used in content, and in metadata. In DITA, taxonomies are created using *subject scheme maps*. When you are authoring, many of the values you choose from have been defined in *subject scheme maps*.

Migrating MS Office Documents to DITA

Oxygen XML Editor integrates the entire *DITA for Publishers plugins suite* and includes some helpful tools that allows you to migrate content from Microsoft Office® Word (and other similar types of documents) to DITA. Migration from proprietary formats to XML is rarely perfect and manual changes may need to be made to the converted content, but the methods described below should help you find the best approach for your particular case:

Method 1

1. Open the document in MS Office (or other similar application), select all the content, and copy it.
2. Open Oxygen XML Editor and create a new DITA topic.
3. Paste the selected content in **Author** mode. The *Smart Paste functionality* will attempt to convert the content to DITA.

Method 2

1. Save your document as HTML.
2. Once you have converted it to HTML, you have two possibilities:
   - In Oxygen XML Editor, select **File** > **Import** > **HTML File** to import it as XHTML. Then, open the XHTML in Oxygen XML Editor and use one of the ***XHTML to DITA*** *Transformation Scenarios* to convert the content to DITA.
   - Open the HTML file in any Web browser, select all of its content, and copy it. Then, open Oxygen XML Editor, create a new **DITA** topic and paste the selected content in **Author** mode. The *Smart Paste functionality* will attempt to convert the HTML content to DITA.

Method 3

1. Open the document in the free *Libre Office* application and save it as **DocBook**.
2. Open the **DocBook** document in Oxygen XML Editor.

3. Run the predefined *transformation scenario called* ***DocBook to DITA***.
4. You may need to make some manual adjustments for elements that couldn't be mapped.

Method 4

1. If the document is in the MS Word DOCX format, you can open it in the ***Archive Browser*** *view* in Oxygen XML Editor and then open the **document.xml** file contained in the archive.
2. Run the predefined *transformation scenario* called **DOCX DITA**. This scenario runs a build file over the DOCX archive and should produce a DITA project that contains a *DITA map* and multiple topics.
3. You may need to do some manual reconfiguration to map DOCX styles to DITA content.

DITA 1.3 Support

Starting with version 17.1, Oxygen XML Editor includes support for some DITA 1.3 features.

To enable DITA 1.3 support in Oxygen XML Editor and use the DITA Open Toolkit 2.5.2 for publishing, *open the* ***Preferences*** *dialog box* ***(Options > Preferences)***, go to **DITA**, and select the **Built-in DITA OT 2.x** radio button.

The Oxygen XML Editor publication of the full DITA 1.3 specifications can be found at *https://www.oxygenxml.com/dita/1.3/specs/index.html#introduction/dita-release-overview.html*.

The following table is a list of DITA 1.3 features and their implementation status in Oxygen XML Editor:

Table 81: DITA 1.3 Features Implementation Status

Feature	Editing	Publishing [DITA Open Toolkit 2.5.2 is used]
DITA 1.3 DTD, XML Schema, and Relax NG-based maps/topics/tasks/references, etc.	New DITA 1.3 file templates. By default, DITA topics and maps that do not specify version in the DOCTYPE declaration are also considered to be DITA 1.3 Specific annotations presented in the content completion assistance window and documentation tooltips for all new DITA 1.3 elements	N/A
Learning Object and Group maps	New file templates	No specific support implemented
Troubleshooting specialization	Create and edit new troubleshooting topics	No specific support implemented
XML markup domain	Validation and Content Completion	Special rendering in PDF and XHTML-based outputs
Equation and MathML domain	Validation and content completion Display and Insert equations	Special rendering in PDF and XHTML-based outputs

Feature	Editing	Publishing [DITA Open Toolkit 2.5.2 is used]
SVG domain	Validation and content completion Display referenced SVG content	Special rendering in PDF and XHTML-based outputs
Other new DITA 1.3 elements (**div**, **strike-through**, **overline**, etc)	Validation and Content Completion	Special rendering in PDF and XHTML-based outputs
Release management domain	Validation and Content Completion	No specific support implemented
Scoped keys	Define key scopes Validate and check for completeness Resolve **keyrefs** and **conkeyrefs** taking key scopes into account Key scope information is displayed in a tooltip when hovering over an item in the **DITA Maps Manager**	Partially implemented (Various issues may still be encountered)
Branch filtering	Display, create, and edit **ditavalref** elements	Partially implemented (Various issues may still be encountered)
Key-based cross deliverable addressing	Special display for references to *DITA maps* with **scope="peer"** and a defined **keyscope** Gather and present keys from peer maps	Not implemented.
Shorthand to address syntax that identifies elements in the same topic	Properly resolved for validation, links, and conrefs	Implemented
Various table attributes (**orientation**, **rotation**, **scope**, and **headers** on cells)	Not implemented in the Table Properties action support. However, attributes can be changed from the Attributes view	Not implemented
New Map **topicref** attributes (**cascade**, **deliveryTarget**)	Allow setting new attributes, propose proper values for them	Implemented

Related Information:

Watch our DITA 1.3 video tutorial for more information about key scopes and branch filtering.

Active Cell

Active cell refers to the selected cell where data is entered when you begin typing. Only one cell is active at a time. The *active cell* is bounded by a heavy border.

Alternate CSS Style

The ***Alternate CSS Style*** refers to the choices in the bottom half of **Styles** drop-down menu (on the toolbar) that makes it easy to apply style changes to your documents as they appear in **Author** mode and the output without having to edit the CSS stylesheets. By default, the *alternate styles* are applied like layers, they are merged sequentially with the *main CSS style*, and you can activate any number of them. However, if you deselect the ***Enable multiple selection of alternate CSSs*** *option* in the **CSS** subtab of the ***Document Type*** *configuration dialog box*, the *alternate styles* are treated like *main CSS styles* and you can only select one at a time.

For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Anchor

An ***Anchor*** is used in various types of links to take the user to a specific location within the target document. It is designated in a URL or in the value of the `href` attribute with a # symbol followed by the anchor that is defined in a target ID (for example `href="MyTopic.dita#anchor`).

Apache Ant

Apache Ant (Another Neat Tool) is a software tool for automating software build processes.

Block Element

A ***block element*** is intended to be visually separated from its siblings, usually vertically. For instance, paragraphs and list items are *block elements*. It is distinct from a *inline element*, which has no such separation.

Bookmap

A ***bookmap*** is a specialized *DITA map* used for creating books. A *bookmap* supports book divisions such as chapters and book lists such as indexes.

Callout

A ***callout*** is a string of text inside a graphic and is connected to a specific location in a document by a line. Oxygen XML Editor uses callouts to present comments and other types of review modifications.

Canonicalize

To ***canonicalize*** something means to convert it to a standard format that everyone generally uses. When using the term with regards to XML, it refers to the process of converting data that has more than one possible representations into a standardization that conforms to the specification of an XML document or document subset. It is helpful for applications that require the ability to test whether or not the content of an XML document or subset has been changed.

Content Completion Assistant

The ***Content Completion Assistant*** refers to a very helpful mechanism in Oxygen XML Editor that offers a list of proposed items that could be inserted at the current location, depending on the current context, editing mode, and type of document. It also tries to determine the most logical choice in the current editing context and displays that proposal at the beginning of the list.

For more information about this feature and how to invoke it, depending on your editing context, see the following:

- *Content Completion Assistant in Author Mode* on page 553
- *Content Completion Assistant in Text Mode* on page 503
- *Content Completion Assistant in Grid Mode* on page 533

- *Content Completion in SQF* on page 915

Dockable

A ***Dockable*** window is one that can be moved and resized, and either floated or pinned to a location, allowing you to configure the workspace according to your preferences.

Document Fragment

A ***document fragment*** represents a portion of an XML document's tree of nodes or content.

Document Type Association

In general terms, a ***Document Type Association*** is a set of rules that associate a document type with a *framework*. In Oxygen XML Editor, ***Document Type Association*** also specifically refers to a *preferences page* where you can create new custom *frameworks* or edit existing ones. Note that predefined *frameworks* (document types) are read-only, but you can ***Extend*** or ***Duplicate*** them to configure them as custom *frameworks*.

DITA Map

A ***DITA map*** is a component of the DITA *framework* that provides the means for a hierarchical collection of DITA topics that can be processed to form an output. Maps do not contain the content of topics, but only references to them. These are known as topic references. Usually the maps are saved on disk or in a CMS with the extension `.ditamap`.

Maps can also contain relationship tables that establish relationships between the topics contained within the map. Relationship tables are also used to generate links in your published document.

You can use your map or *bookmap* to generate a deliverable using an output type such as XHTML, PDF, HTML Help, or Eclipse Help.

DITA-OT-DIR

DITA_OT_DIR refers to the default directory that is specified for your DITA Open Toolkit distribution in the ***Options*** > ***Preferences*** > ***DITA*** *preferences page*.

For example, if you are using DITA OT 2.5.2, *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/DITA-OT2.x` (or if you are using DITA OT 1.8.5, the default DITA OT directory is: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/DITA-OT`). You can also specify a custom directory.

Foldable Element

A ***foldable element*** refers to elements that can be collapsed and expanded in Oxygen XML Editor. *Foldable elements* are marked with a small triangle (/) on the left side of the editor panel and you can use that triangle to quickly collapse or expand them. This feature is helpful when you are working with large documents and you want to temporarily hide blocks of content. You can right-click the triangle to access additional collapse and expand actions (**Collapse Other Folds**, **Collapse Child Folds**, **Expand Child Folds**, **Expand All**).

Framework

A ***framework*** refers to a package that contains resources and configuration information to provide ready-to-use support for an XML vocabulary or document type. Oxygen XML Editor includes a ***Document Type Configuration Dialog Box*** that allows you to define a set of rules and customize various authoring mechanisms for new or existing *frameworks*.

For advanced details about customizing your own *framework*, see the *Advanced Framework Customization* on page 1385 section.

Global Options

Global Options refers to the *storage option* in the Oxygen XML Editor preference pages (**Options** > **Preferences**). If you select ***Global Options***, the options in that particular preferences page are stored locally on your computer and are not accessible to other users (unless you *export them into an XML options file* that can then be shared).

IDML

IDML is an abbreviation for Adobe InDesign Markup files.

Inline Element

An ***inline element*** is intended to be displayed in the same line of text as its siblings or the surrounding text. For instance, strong and emphasis in HTML are *inline elements*. It is distinct from a *block element*, which is visually separated from its siblings.

Java Archive

Java Archive (JAR) is an archive file format. *JAR* files are built on the ZIP file format and have the `.jar` file extension. Computer users can create or extract *JAR* files using the `jar` command or an archive tool.

Key Space

A ***Key Space*** is established when a *root map* defines a set of effective key bindings. When Oxygen XML Editor processes key references, it determines the effective binding of a given key to a resource in the context of the *specified root map*.

Keystore

A ***Keystore*** is an encrypted file that contains private keys and certificates. There are two types of *keystores* that are supported in Oxygen XML Editor:

- **Java Key Store (JKS)**
- **Public-Key Cryptography Standards version 12 (PKCS-12)**

Main CSS Style

The ***Main CSS Style*** refers to the selection in the top half of the **Styles** drop-down menu (on the toolbar) that makes it easy to quickly change the look of your documents as they appear in **Author** mode and the output without having to edit the CSS stylesheets. The *main CSS* applies to the whole document and you can also select one or more *alternate styles* (listed in the bottom half of the drop-down menu) that behave like layers and are merged sequentially with the *main CSS style*.

For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Master File

A ***Master File*** typically refers to the root of an imported or included tree of modules and this support helps you simplify the configuration and development of XML projects. For more information, see the *Master Files Support* on page 466 section.

Named User

Named User is defined as an individual full or part-time employee who is authorized by *You* (the individual or entity who owns the rights to Oxygen XML Editor) to use the software regardless of whether or not the individual is actively using the software at any given time. To avoid any doubt, *Named User* licenses cannot be shared amongst multiple individuals and separate *Named User* licenses must be purchased for each individual user.

A *Named User* license may not be reassigned to another employee except in the following circumstances:

- (a) Upon termination of the *Named User's* employment with your company.
- (b) Permanent reassignment of a *Named User* to a position that does not involve the use of the Software.

For example, suppose Jane has been assigned an Oxygen XML license and she leaves your company. When she leaves, you can simply reassign her license to John, her replacement. In the event that you do reassign the *Named User* license in accordance with the restrictions above, you do not need to notify Syncro of such a reassignment.

Note: This definition is taken from the Oxygen XML Editor *End User License Agreement*.

Perspective

In Oxygen XML Editor, a ***perspective*** refers to an interface layout geared towards a specific editing environment. Each *perspective* includes a unique set of interface objects, toolbars, views, and features. You can change the *perspective* by selecting the respective icon () in the top-right corner of Oxygen XML Editor or by selecting the *perspective* from the **Window** > **Open Perspective** menu.

The *perspectives* that are available in Oxygen XML Editor are:

- ***Editor*** - The most commonly used *perspective* and it is used to edit XML documents.
- ***XSLT Debugger*** - Used to detect problems in an XSLT transformation by executing the process step by step in a controlled environment.
- ***XQuery Debugger*** - Used to detect problems in an XQuery transformation process by executing the process step by step in a controlled environment
- ***Database*** - Used to browse and manage databases.

Plugin

A ***plugin*** (also referred to as *add-on* or *extension*) is a component that adds specific features to an existing application. Oxygen XML Editor supports *plugins* to enable numerous customizations.

For more information, see the following topics:

- *Installing and Updating Add-ons* on page 49
- *Automatic and Manual Methods for Installing Plugins*
- *Packing and Deploying Plugins or Frameworks as Add-ons* on page 1421
- *Add-ons Preferences* on page 58
- *Extending Oxygen XML Editor with Plugins* on page 1555
- *General Configuration of an Oxygen XML Editor Plugin* on page 1555

Pretty-Print

Pretty-print refers to formatting and indenting the source code in **Text** mode to make the content easier to view and analyze. The formatting actions that are available in Oxygen XML Editor include:

- **Format and Indent Element** - Available in the **Source** submenu of the contextual menu for the current element.
- **Format and Indent** - Available on the toolbar for the entire currently opened document.
- **Format and Indent Files** - Available in the contextual menu of the ***Project*** *view* for one or more selected files.

Project Options

Project Options refers to the *storage option* in the Oxygen XML Editor preference pages (**Options** > **Preferences**). If you select ***Project Options***, the options in that particular preferences page are stored at project level in the project file (`.xpr`), which can easily be *shared with other users*.

QName

QName stands for "qualified name" and defines a valid identifier for elements and attributes. *QNames* are used as URI references to reference particular elements or attributes within XML documents.

Quick Assist

The ***Quick Assist*** feature gives you easy access to some of the most commonly used actions for the specific type of document you are editing. If one or more actions are available in the current context, they are accessible via a yellow bulb help () placed at the current line in the stripe on the left side of the editor in **Text** mode. You can also invoke the quick assist menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

Quick Fix

The ***Quick Fix*** support in Oxygen XML Editor helps you resolve errors that appear in an XML document by offering proposals to fix problems such as missing required attributes or invalid elements. *Quick Fixes* are available in **Text** mode and **Author** mode and they can be presented and activated in several ways.

- When hovering over an area of text where a validation error or warning occurs, the *Quick Fix* proposals can be presented as links in a tooltip pop-up window.
- When hovering over an error or warning in **Author** mode, the *Quick Fix* proposals are presented in a small drop-down menu.
- If you place the cursor in the highlighted area where a validation error or warning occurs, a *Quick Fix* icon () is displayed in the stripe on the left side of the editor. Clicking that icon will allow you select from the available proposals.
- If you place the cursor in the highlighted area where a validation error or warning occurs, you can also access the *Quick Fix* menu by pressing **Alt + 1 (Command + Alt + 1 on OS X)** on your keyboard.

Oxygen XML Editor also provides support for *defining and customizing a library of Quick Fixes using the Schematron language*.

Root Map

A ***Root Map*** (or master map) specifies a *DITA map* that defines a hierarchical structure of submaps that are contained within the *root map*. Essentially, the *root map* defines a scope and provides the mechanism to allow your defined keys to be propagated throughout the entire map structure (this mechanism is also known as a *key space*).

In Oxygen XML Editor, the **DITA Maps Manager** includes an *option on its toolbar where you can easily specify the root map*, but there are also several other ways to *select or change the root map*.

Space-Preserved Element

A ***spaced-preserved element*** refers to elements that require white spaces and line endings to be preserved (for example, DITA `codeblock` and `pre` elements).

Subject Scheme Map

A ***Subject Scheme Map*** allows you to create custom controlled attribute values and to manage metadata. *Subject scheme maps* use a key definition to define a collection of controlled values rather than a collection of topics. The highest level of map that uses the set of controlled values must reference the *subject scheme map* in which those controlled values are defined.

A controlled value is a keyword that can be used as a value in a metadata attribute. For example, the `@audience` metadata attribute may take a value that identifies the user group associated with a particular content unit (for medical equipment, that might include *therapist*, *oncologist*, *surgeon*, *radiologist*, and so on). In a *subject scheme map*, you can define a list of these audience values and you can then use these values to profile your content. For more information, see *Customizing Profiling Values with a Subject Scheme Map* on page 1917.

.

Track Changes

The *Track Changes* feature allows you to review changes that you or other authors have made and then accept or reject them. You can also manage the visualization mode of the tracked changes, add comments to changes, and mark them as being done. These actions are easily accessible from contextual menus, the toolbar, or the ***Review*** *view*.

For more information about this feature, see *Managing Tracked Changes* on page 566.

Working Set

A ***Working Set*** refers to a set of files that will be used for the scope of search and refactoring operations. Many of the search and refactoring wizards include a step where you can specify the scope for the operation and you can choose one or more *working sets* to restrict the scope to that specified set of files.

XML Catalog

An ***XML Catalog*** maps a system ID or a URI reference for a resource (stored either remotely or locally) to a local copy of the same resource. Whenever XML processing relies on external resources (such as referenced schemas and stylesheets), the use of an *XML Catalog* becomes a necessity when Internet access is not available or the connection is slow.

Oxygen XML Editor includes default global catalogs as well as default catalogs for each of the built-in *frameworks*, and you can also create your own. Oxygen XML Editor uses these *XML Catalogs* to resolve references for document validation and transformations. For more information, see *Working with XML Catalogs* on page 695.

Trademarks. Many of the designations used by manufacturers and sellers to distinguish their products are claimed as trademarks. Where those designations appear in this document, and Syncro Soft SRL was aware of a trademark claim, the designations have been rendered in caps or initial caps.

Notice. While every precaution has been taken in the preparation of this document, the publisher and the author assume no responsibility for errors or omissions, or for damages resulting from the use of information contained in this document or from the use of programs and source code that may accompany it. In no event shall the publisher and the author be liable for any loss of profit or any other commercial damage caused or alleged to have been caused directly or indirectly by this document.

Link disclaimer. Syncro Soft SRL is not responsible for the contents or reliability of any linked Web sites referenced elsewhere within this documentation, and Syncro Soft SRL does not necessarily endorse the products, services, or information described or offered within them. We cannot guarantee that these links will work all the time and we have no control over the availability of the linked pages.

Warranty. Syncro Soft SRL provides a limited warranty on this product. Refer to your sales agreement to establish the terms of the limited warranty. In addition, Oxygen XML Editor End User License Agreement, as well as information regarding support for this product, while under warranty, is available through the *Oxygen XML Editor website*.

Third-party components. Certain software programs or portions thereof included in the Product may contain software distributed under third party agreements ("Third Party Components"), which may contain terms that expand or limit rights to use certain portions of the Product ("Third Party Terms"). Information identifying Third Party Components and the Third Party Terms that apply to them is available on the *Oxygen XML Editor website*.

Documentation. For the most current versions of documentation, see the *Oxygen XML Editor website*.

Contact Syncro Soft SRL. Syncro Soft SRL provides telephone numbers and e-mail addresses for you to report problems or to ask questions about your product, see the *Oxygen XML Editor website*.
