Since various parameters can be specified, this custom operation can also be used for other similar tasks. The following image shows the parameters that can be specified in our example of the custom operation to convert an attribute to an element:

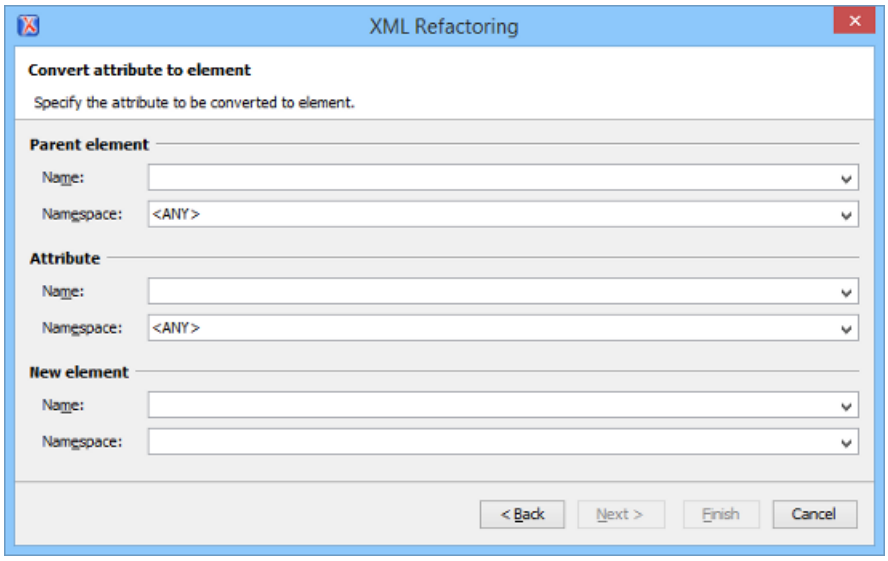

Figure 404: Example: XML Refactoring Wizard for a Custom Operation

XSLT Stylesheet for Creating a Custom Operation

To demonstrate creating a custom operation, consider that we have a task where we need to convert an attribute into an element and insert it inside another element. A specific example would be if you have a project with a variety of `image` elements where a deprecated `alt` attribute was used for the description and you want to convert all instances of that attribute into an element with the same name and insert it as the first child of the `image` element.

Thus, our task is to convert this attribute into an element with the same name and insert it as the first child of the image element.

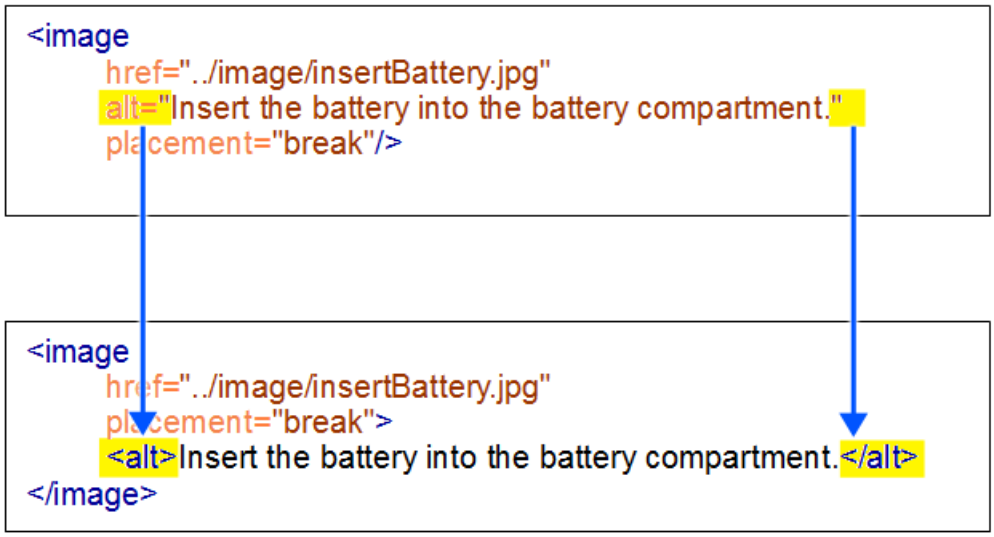

Figure 405: Example: Custom XML Refactoring Operation

We can use an XSLT stylesheet to implement the new custom XML refactoring operation. The second requirement is an *XML Refactoring operation descriptor file* that contains the path to the XSLT stylesheet.

Example of an XSLT Script for Creating a Custom Operation to *Convert an Attribute to an Element*

The XSLT stylesheet does the following:

- Iterates over all elements from the document that have the specified local name and namespace.

- Finds the attribute that will be converted to an element.
- Adds the new element as the first child of the parent element.

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  exclude-result-prefixes="xs"
  xmlns:xr="http://www.oxygenxml.com/ns/xmlRefactoring"
  version="2.0">

  <xsl:import
href="http://www.oxygenxml.com/ns/xmlRefactoring/resources/commons.xsl"/>

  <xsl:param name="element_localName" as="xs:string" required="yes"/>
  <xsl:param name="element_namespace" as="xs:string" required="yes"/>
  <xsl:param name="attribute_localName" as="xs:string" required="yes"/>
  <xsl:param name="attribute_namespace" as="xs:string" required="yes"/>
  <xsl:param name="new_element_localName" as="xs:string" required="yes"/>
  <xsl:param name="new_element_namespace" as="xs:string" required="yes"/>

  <xsl:template match="node() | @*">
      <xsl:copy>
          <xsl:apply-templates select="node() | @*"/>
      </xsl:copy>
  </xsl:template>
  <xsl:template match="//*[xr:check-local-name($element_localName, ., true())
     and
        xr:check-namespace-uri($element_namespace, .)]">

      <xsl:variable name="attributeToConvert"
         select="@*[xr:check-local-name($attribute_localName, ., true())
     and
        xr:check-namespace-uri($attribute_namespace, .)]"/>

      <xsl:choose>
          <xsl:when test="empty($attributeToConvert)">
              <xsl:copy>
                  <xsl:apply-templates select="node() | @*"/>
              </xsl:copy>
          </xsl:when>
      <xsl:otherwise>
          <xsl:copy>
              <xsl:for-each select="@*[empty(. intersect $attributeToConvert)]">
                  <xsl:copy-of select="."/>
              </xsl:for-each>
                <!-- The new element namespace -->
                <xsl:variable name="nsURI" as="xs:string">
                    <xsl:choose>
           <xsl:when test="$new_element_namespace eq $xr:NO-NAMESPACE">
                           <xsl:value-of select="''"/>
                       </xsl:when>
                       <xsl:otherwise>
                           <xsl:value-of select="$new_element_namespace"/>
                       </xsl:otherwise>
                   </xsl:choose>
                </xsl:variable>
          <xsl:element name="{$new_element_localName}" namespace="{$nsURI}">
                  <xsl:value-of select="$attributeToConvert"/>
                </xsl:element>
              <xsl:apply-templates select="node()"/>
          </xsl:copy>
        </xsl:otherwise>
      </xsl:choose>
  </xsl:template>
</xsl:stylesheet>
```

Note: The XSLT stylesheet imports a module library that contains utility functions and variables. The location of this module is resolved via an *XML Catalog* set in the XML Refactoring *framework*.

Example of an Operation Descriptor File That References the XSLT Stylesheet for Creating a Custom Operation to *Convert an Attribute to an Element*

After you have developed the XSLT stylesheet, you have to create an XML Refactoring operation descriptor. This descriptor is used by the application to load the operation details such as name, description, or parameters.

```
<?xml version="1.0" encoding="UTF-8"?>

<refactoringOperationDescriptor
 xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
 xmlns="http://www.oxygenxml.com/ns/xmlRefactoring"
 id="convert-attribute-to-element"
 name="Convert attribute to element">
 <description>Converts the specified attribute to an element.
           The new element will be inserted as first child of the attribute's
           parent element.</description>
 <!-- For the XSLT stylesheet option uncomment the following line and comment
           the line referring the XQuery Update script -->
```

```
 <!-- <script type="XSLT" href="convert-attribute-to-element.xsl"/> -->
 <script type="XQUERY_UPDATE" href="convert-attribute-to-element.xq"/>
  <parameters>
   <description>Specify the attribute to be converted to element.</description>
    <section label="Parent element">
     <elementParameter id="elemID">
      <localName label="Name" name="element_localName" allowsAny="true">
       <description>Local name of the parent element.</description>
        </localName>
       <namespace label="Namespace" name="element_namespace" allowsAny="true">
         <description>Local name of the parent element</description>
       </namespace>
     </elementParameter>
    </section>
    <section label="Attribute">
     <attributeParameter dependsOn="elemID">
      <localName label="Name" name="attribute_localName">
       <description>Name of the attribute to be converted.</description>
      </localName>
     <namespace label="Namespace" name="attribute_namespace" allowsAny="true">
       <description>Namespace of the attribute to be converted.</description>
     </namespace>
     </attributeParameter>
    </section>
    <section label="New element">
        <elementParameter>
           <localName label="Name" name="new_element_localName">
               <description>The name of the new element.</description>
           </localName>
           <namespace label="Namespace" name="new_element_namespace">
               <description>The namespace of the new element.</description>
           </namespace>
        </elementParameter>
    </section>
  </parameters>
</refactoringOperationDescriptor>
```

Note: If you are using an XSLT file, the line with the `script` element would look like this:

```
<script type="XSLT" href="convert-attribute-to-element.xsl"/>
```

Results

After you have created these files, copy them into a folder *scanned by Oxygen XML Editor when it loads the custom operation*. When the XML Refactoring tool is started again, you will see the created operation.

Since various parameters can be specified, this custom operation can also be used for other similar tasks. The following image shows the parameters that can be specified in our example of the custom operation to convert an attribute to an element:

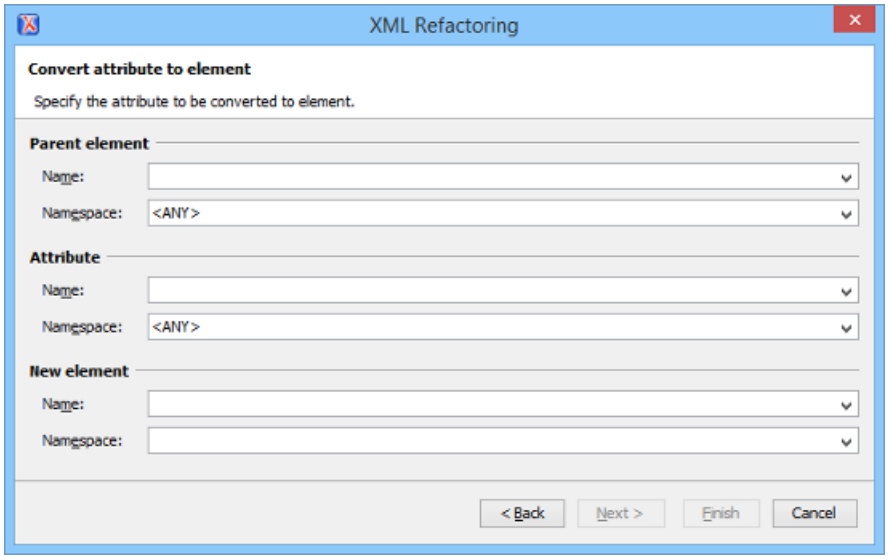

Figure 406: Example: XML Refactoring Wizard for a Custom Operation

Using Saxon Extension Functions to Allow Custom Refactoring Operations to Read and Modify Content Outside the Root Node

One advantage to using an XSLT stylesheet is that there is limitation when using an *XQuery Update script* in that refactoring operations can only be performed on *comments* or *processing instructions* that are inside the root element. Thus, using the XQuery method, *comments* or *processing instructions* that are in any node before or after the root element cannot be modified by an XML Refactoring operation.

The XSLT stylesheet method offers a work around to this limitation through the use of some Saxon extension functions.

To illustrate the use of these functions, consider the following sample XML file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!-- comment before root -->
<?pi before root ?>
<root>
    <child></child>
</root>
<!-- comment after root -->
<?pi after root ?>
```

The following Saxon extension functions can be used to read and modify content outside the root node:

Note: They belong to the `http://www.oxygenxml.com/ns/xmlRefactoring/functions` namespace.

- **get-content-after-root()** - Returns the content after root as `xs:string`.

  For the XML above, the call of this function will return the following string value:

  ```
  <!-- comment after root -->
  <?pi after root ?>
  ```

- **set-content-after-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

  The function call `set-content-after-root('<!-- Inserted comment -->')` will result in replacing the nodes after the root element with the comment passed as string argument. The XML document will be modified as follows:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <!-- comment before root -->
  <?pi before root ?>
  <root>
      <child></child>
  </root><!-- Inserted comment -->
  ```

- **get-content-before-root()** - Returns the content before root as `xs:string`.

  For the XML above, the call of this function will return the following string value:

  ```
  <?xml version="1.0" encoding="UTF-8"?>
  <!-- comment before root -->
  <?pi before root ?>
  ```

- **set-content-before-root(xs:string)** - Updates the content that will be serialized in the refactored document after the root node.

  The function call `set-content-before-root('<!-- Inserted comment -->')` will result in replacing the nodes before the root element with the comment passed as string argument. The XML document will be modified as follows:

  ```
  <!-- Inserted comment --><root>
      <child></child>
  </root>
  <!-- comment after root -->
  <?pi after root ?>
  ```

XSLT Example:

To process content after the root node, the XSLT would look like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema" exclude-result-prefixes="xs"
```

```
    xmlns:xrf="http://www.oxygenxml.com/ns/xmlRefactoring/functions" version="3.0">
    <xsl:template match="/">
        <!-- The comment content that will be inserted after the root element -->
        <xsl:variable name="commentAsText">&lt;!-- COMMENT ADDED FROM XR OPERATION--></xsl:variable>
        <!-- Retrieve the content after the root element as is -->
        <xsl:variable name="after-root-content" as="xs:string"
                      select="xrf:get-content-after-root()"/>

        <xsl:variable name="processedContent"
                      select="concat($after-root-content, $commentAsText)"/>

        <!-- Update the content after the root element -->
        <xsl:value-of select="xrf:set-content-after-root($processedContent)"/>

        <xsl:apply-templates/>
    </xsl:template>

    <xsl:template match="node() | @*">
        <xsl:copy>
            <xsl:apply-templates select="node() | @*"/>
        </xsl:copy>
    </xsl:template>
</xsl:stylesheet>
```

Note: The above XSLT retrieves the nodes after the root element as string, appends a new comment, and then sets back the updated content into the XML document.

Storing and Sharing Refactoring Operations

Oxygen XML Editor scans the following locations when looking for XML Refactoring operations to provide flexibility:

- A `refactoring` folder, created inside a directory that is associated to a *framework* you are customizing. To associate the parent directory to the *framework*, you need to add it in the ***Classpath*** *tab of the* ***Document type*** *configuration dialog box*.
- A folder that you specify in the ***Load additional refactoring operations from*** *text box* in the ***XML Refactoring*** *preferences page*.

  Note: If you share a project with your team, you can also share the custom operation by doing the following:

  1. Save the custom operation in a folder that is part of your project.
  2. Switch the **XML Refactoring** option page to *project level*:
     a. *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to ***XML > XML Refactoring***.
     b. Select ***Project Options*** at the bottom of the dialog box.
  3. In the ***Load additional refactoring operations from*** *text box*, use the *${pd} editor variable* so that the folder path is declared relative to the project.
- A folder specified by the *XML Refactoring Operations Plugin Extension*.
- The `refactoring` folder from the Oxygen XML Editor installation directory (*`[OXYGEN_INSTALL_DIR]`*`/refactoring/`).

Sharing Custom Refactoring Operations

The purpose of Oxygen XML Editor scanning multiple locations for the XML Refactoring operations is to provide more flexibility for developers who want to share the refactoring operations with the other team members. Depending on your particular use case, you can attach the custom refactoring operations to other resources, such as *framework* or projects.

After storing custom operations, you can share them with other users by sharing the resources.

Localizing XML Refactoring Operations

Oxygen XML Editor includes localization support for the XML refactoring operations.

The translation keys for the built-in refactoring operations are located in *`[OXYGEN_INSTALL_DIR]`*`/refactoring/i18n/translation.xml`.

The localization support is also available for custom refactoring operations. The following information can be translated:

- The operation `name`, `description`, and `category`.

- The `description` of the `parameters` element.
- The `label`, `description`, and `possibleValues` for each `parameter`.

Translated refactoring information uses the following form:

```
${i18n(translation_key)}
```

Oxygen XML Editor scans the following locations to find the `translation.xml` files that are used to load the translation keys:

- A `refactoring/i18n` folder, created inside a directory that is associated to a customized *framework*.
- A `i18n` folder, created inside a directory that is associated to a customized *framework*.
- An `i18n` folder inside any specified folder. In this case, you need to *open the **Preferences** dialog box **(Options > Preferences)***, go to **XML** > **XML Refactoring**, and specify the folder in the **Load additional refactoring operations from** text box.
- An `i18n` folder located in directories specified through the *XML Refactoring Operations Plugin Extension*.
- The `refactoring/i18n` folder from the Oxygen XML Editor installation directory (*`[OXYGEN_INSTALL_DIR]`*`/refactoring/i18n`).

Example: Refactoring Operation Descriptor File with *i18n* Support

```
<?xml version="1.0" encoding="UTF-8"?>

<refactoringOperationDescriptor
    xmlns="http://www.oxygenxml.com/ns/xmlRefactoring" id="remove_text_content"
           name="${i18n(Remove_text_content)}">
    <description>${i18n(Remove_text_content_description)}</description>
    <script type="XQUERY_UPDATE" href="remove_text_content.xq"/>
    <parameters>
        <description>${i18n(parameters_description)}</description>
        <parameter label="${i18n(Element_name)}" name="element_localName"
                      type="NC_NAME">
            <description>${i18n(Element_name_descriptor)}</description>
            <possibleValues>
                <value default="true" name="value1">${i18n(value_1)}</value>
                <value name="value2">${i18n(value_2)}</value>
            </possibleValues>
        </parameter>
    </parameters>
</refactoringOperationDescriptor>
```

Editing XSLT Stylesheets

Oxygen XML Editor includes a built-in editor for XSLT stylesheets. This section presents the features of the XSLT editor and how these features can be used. The features of the XSLT editor include:

- **Create new XSLT files and templates** - You can use the built-in new file wizards to *create new XSLT documents or templates*.
- **Open and Edit XSLT files** - XSLT files can be opened and edited in the source editor (***Text** mode*).
- **Visual Editing** - XSLT stylesheets are rendered, and can be edited, in the *visual **Author** editing mode*.
- **Validation** - Presents validation errors in XSLT files.
- **Content completion** - Offers proposals for properties and the values that are available for each property.
- **Syntax highlighting** - The syntax highlighting in Oxygen XML Editor makes XSLT files more readable.

Editing XSLT Stylesheets in the Master Files Context

Smaller interrelated modules that define a complex stylesheet cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, a function defined in a main stylesheet is not visible when you edit an included or imported module. Oxygen XML Editor provides the support for defining the main module (or modules), allowing you to edit any of the imported/included files in the context of the larger stylesheet structure.

You cat set a main XSLT stylesheet either using the *master files support from the **Project** view*, or using a validation scenario.

To set a *master file* using a validation scenario, add validation units that point to the main modules. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main stylesheet. In this case, it considers the current module as the main stylesheet.

The advantages of editing in the context of *master file* include:

- Correct validation of a module in the context of a larger stylesheet structure.
- *Content Completion Assistant* displays all components valid in the current context.
- The ***Outline*** *view* displays the components collected from the entire stylesheet structure.

For more information about editing XSLT stylesheets in the *master files* context, watch our video demonstration:

XSLT Resource Hierarchy/Dependencies View on page 738
XSLT Component Dependencies View on page 740

Validating XSLT Stylesheets

Numerous XSLT code quality assurance checks are done during automatic validation to help you keep your stylesheets valid and well formed. Oxygen XML Editor performs the validation of XSLT documents with the help of an XSLT processor *that you can configure in the preferences pages* according to the XSLT version.

For XSLT 1.0, the options are: Xalan, Saxon 6.5.5, Saxon 9.7.0.19 and *a JAXP transformer specified by the main Java class.* For XSLT 2.0, the options are: Saxon 9.7.0.19 and *a JAXP transformer specified by the main Java class.* For XSLT 3.0, the options are Saxon 9.7.0.19 and *a JAXP transformer specified by the main Java class.*

To access the *XSLT preferences* quickly, use the **Validation options** action from the **Document** > **Validate** menu.

Creating a Validation Scenario for XSLT Stylesheets

You can validate an XSLT document using the engine defined in the transformation scenario, or a custom validation scenario. If you choose to validate using the engine from transformation scenario, and a transformation scenario is not associated with the current document or the engine has no validation support, the default engine is used. To set the default engine, *open the* ***Preferences*** *dialog box* ***(Options*** *>* ***Preferences)*** and go to **XML** > **XSLT/FO/XQuery** > **XSLT**.

You can also create new validation scenarios or edit existing ones, and you can add *JARS* and classes that contain extension functions. To create or edit a validation scenario for an XSLT stylesheet, follow these steps:

1. With the XSLT file opened in Oxygen XML Editor, select the **Configure Validation Scenario(s)** from the **Document** > **Validate** menu, or the **Validation** toolbar drop-down menu, or from the **Validate** submenu when invoking the contextual menu on the XSLT file in the ***Project*** *view*.
   The **Configure Validation Scenario(s)** dialog box is displayed. It contains the existing scenarios, organized in categories depending on the type of file they apply to. You can use the options in the **Settings** drop-down menu to filter which scenarios are shown.
2. To edit an existing scenario, select the scenario and press the **Edit** button. If you try to edit one of the *read-only* predefined scenarios, Oxygen XML Editor creates a customizable duplicate (you can also use the **Duplicate** button).
3. To add a new scenario, press the **New** button.
   The **New scenarios** dialog box is displayed. It lists all validation units of the scenario.

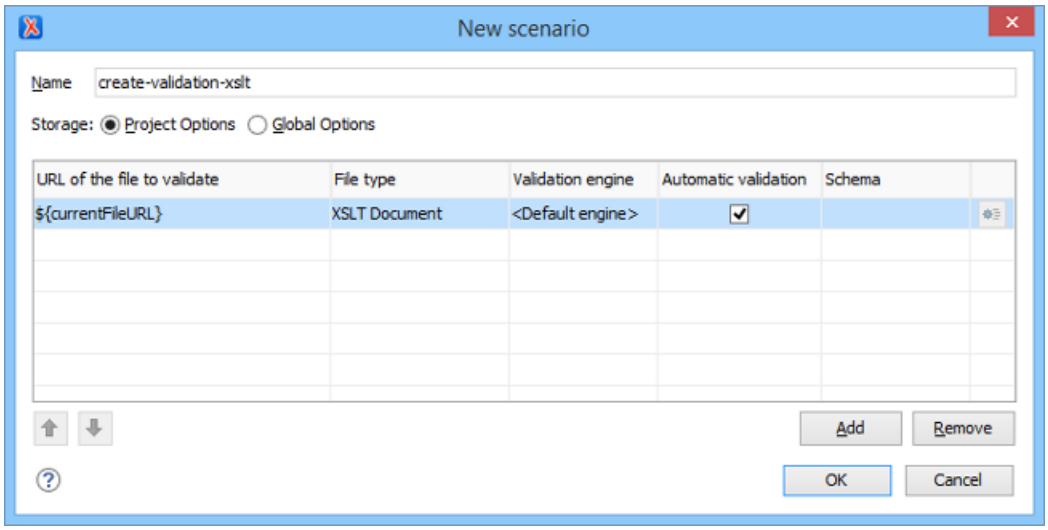

Figure 407: Add / Edit a Validation Unit

4. Configure the following information in this dialog box:
   a) **Name** - The name of the validation scenario.
   b) **Storage** - You can choose between storing the scenario in the ***Project Options*** or ***Global Options***.
   c) **URL of the file to validate** - In most cases, leave this field as the default selection (the URL of the current file). If you want to specify a different URL, double-click its cell and enter the URL in the text field, select it from the drop-down list, or use the **Browse** drop-down menu or ***Insert Editor Variable*** button.
   d) **File type** - The file type should be **XSLT Document**.
   e) **Validation engine** - Click the cell to select a validation engine. You must select an engine to be able to add or edit extensions.
   f) **Automatic validation** - If this option is selected, the validation operation defined by this row is also used by *the automatic validation feature*.
5. To add or edit extensions, click the **Edit extensions** button. This button is only available if the **File type** is set as **XSLT Document** and a **Validation engine** is chosen.
   The **Libraries** dialog box is opened. It is used to specify the *JARS* and classes that contain extension functions called from the XSLT file of the current validation scenario. They will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item and press the **Move up** or **Move down** buttons.
6. Press **OK** to close the **New scenario** dialog box.
   The newly created validation scenario is now included in the list of scenarios in the **Configure Validation Scenario(s)** dialog box. You can select the scenario in this dialog box to associate it with the current XSLT document and press the **Apply associated** button to run the validation scenario.

Validating XSLT Stylesheets with Custom Engines

If you need to validate an XSLT stylesheet with a validation engine that is different from the built-in engine, you can configure external engines as custom XSLT validation engines in the Oxygen XML Editor preferences. After a custom validation engine is *properly configured*, it can be applied on the current document by selecting it from the list of custom validation engines in the **Validation** toolbar drop-down menu. The document is validated against the schema declared in the document.

By default, there are two validators that are configured for XSLT stylesheets:

- **MSXML 4.0** - included in Oxygen XML Editor (Windows edition). It is associated to the XSL Editor type in *Preferences page.*
- **MSXML.NET** - included in Oxygen XML Editor (Windows edition). It is associated to the XSL Editor type in *Preferences page.*

Validating XSLT Stylesheets that Call Java Extensions

It is possible to validate XSLT that call Java extensions. This is achieved through a transformation scenario in which the Java extensions are specified, and the default validation will be processed using the parameters defined in the transformation scenario.

To validate XSLT with Java extensions, follow this procedure:

1. Create an *XSLT transformation scenario* for your XSLT document (select **Configure Transformation Scenario(s)** action from the toolbar, then click **New**, and select **XSLT transformation**).
2. In the **New scenario** dialog box, click the **Extensions** button (in the **XSLT** tab), specify the Java extensions (JAR libraries) that are needed, and click **OK**.
3. Once you are finished configuring the transformation scenario, click **OK**, then select **Save and close**.
4. Use the **Validate** button on the toolbar **(or Ctrl + Shift + V (Command + Shift + V on OS X))** and the default validation will detect and use the transformation scenario profile you just configured and saved.

XSLT Quick Fix Support

The Oxygen XML Editor *Quick Fix support* helps you resolve various errors that appear in a stylesheet by proposing *Quick Fixes* to problems such as missing templates, misspelled template names, missing functions, or references to an undeclared variable or parameter.

To activate this feature, hover over or place the cursor in the highlighted area of text where a validation error or warning occurs. If a *Quick Fix* is available for that particular error or warning, you can access the *Quick Fix* proposals with any of the following methods:

- When hovering over the error or warning, the proposals are presented in a tooltip pop-up window.
- If you place the cursor in the highlighted area where a validation error or warning occurs, a *Quick Fix* icon ( ) is displayed in the stripe on the left side of the editor. If you click this icon, Oxygen XML Editor displays the list of available fixes.
- With the cursor placed in the highlighted area of the error or warning, you can also invoke the *Quick Fix* menu by pressing **Alt + 1 (Command + Alt + 1 on OS X)** on your keyboard.

Note: The *Quick Fixes* are available only when validating an XSLT file with Saxon HE/PE/EE.

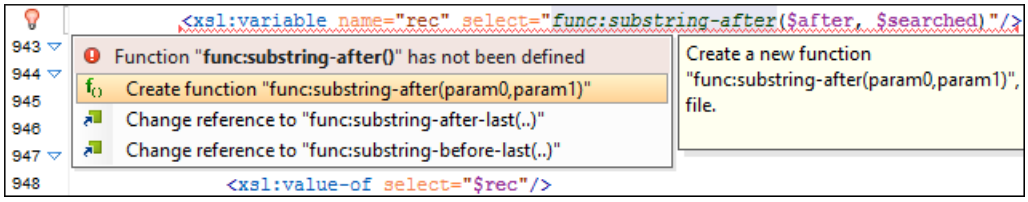

Figure 408: Example of an Undefined XSLT Functions Quick Fix

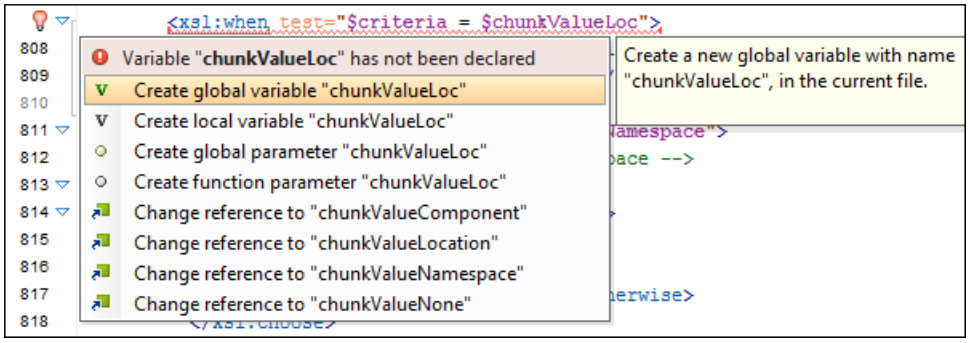

Figure 409: Example of an Undeclared XSLT Variables/Parameters Quick Fix

Oxygen XML Editor provides XSLT *Quick Fixes* for the following types of instances:

- **Template does not exist**, when the template name referenced in a `call-template` element does not exist. The following fixes are available:
  - **Create template "templateName"** - creates a template and generates its corresponding parameters. The template name and parameter names and types are collected from the `call-template` element.
  - **Change reference to "newTemplateName"** - changes the name of the missing template referenced in the `call-template` element. The proposed new names are the existing templates with names similar with the missing one.
- **Variable/Parameter not declared**, when a parameter or variable reference cannot be found. The following fixes are available:
  - **Create global variable "varName"** - creates a global variable with the specified name in the current stylesheet. The new variable is added at the beginning of the stylesheet after the last global variable or parameter declaration.
  - **Create global parameter "paramName"** - creates a global parameter with the specified name in the current stylesheet. The new parameter is added at the beginning of the stylesheet after the last global parameter or variable declaration.
  - **Create local variable "varName"** - creates a local variable with the specified name before the current element.
  - **Create template parameter "paramName"** - creates a new parameter with the specified name in the current template. This fix is available if the error is located inside a template.
  - **Create function parameter "paramName"** - creates a new parameter with the specified name in the current function. This fix is available if the error is located inside a function.
  - **Change reference to "varName"** - changes the name of the referenced variable/parameter to an existing local or global variable/parameter, that has a similar name with the current one.
- **Parameter from a called template is not declared**, when a parameter referenced from a `call-template` element is not declared. The following fixes are available:
  - **Create parameter "paramName" in the template "templateName"** - creates a new parameter with the specified name in the referenced template.
  - **Change "paramName" parameter reference to "newParamName"** - changes the parameter reference from the `call-template` element to a parameter that is declared in the called template.
  - **Remove parameter "paramName" from call-template** - removes the parameter with the specified name from the `call-template` element.
- **No value supplied for required parameter**, when a required parameter from a template is not referenced in a `call-template` element. The following quick-fix is available::
  - **Add parameter "paramName" in call-template** - creates a new parameter with the specified name in call-template element.
- **Function "prefix:functionName()" has not been defined**, when a function declaration is not found. The following *Quick Fixes* are available:
  - **Create function "prefix:functionName(param1, param2)"** - creates a new function with the specified signature, after the current top level element from stylesheet.
  - **Change function to "newFunctionName(..)"** - changes the referenced function name to an already defined function. The proposed names are collected from functions with similar names and the same number of parameters.
- **Attribute-set "attrSetName" does not exist**, when the referenced attribute set does not exist. The following *Quick Fixes* are available:
  - **Create attribute-set "attrSetName"** - creates a new attribute set with the specified name, after the current top level element from stylesheet.
  - **Change reference to "attrSetName"** - changes the referenced attribute set to an already defined one.
- **Character-map "chacterMap" has not been defined**, when the referenced character map declaration is not found. The following *Quick Fixes* are available:
  - **Create character-map "characterMapName"** - creates a new character map with the specified name, after the current top level element from stylesheet.
  - **Change reference to "characterMapName"** - changes the referenced character map to an already defined one.

Content Completion in XSLT Stylesheets

The list of proposals offered by the *Content Completion Assistant* in XSLT are context-sensitive and includes proposals that are valid at the current cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

You can enhance the list of proposals by specifying an additional schema. This schema is defined in the ***Content Completion / XSLT** preferences* page and can be any of the following: XML Schema, DTD, RELAX NG schema, or NVDL schema.

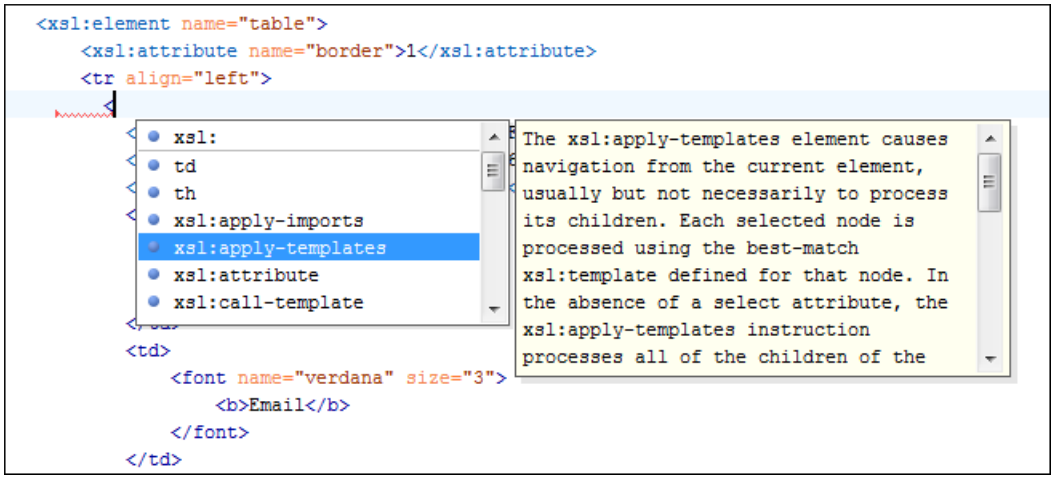

Figure 410: XSLT Content Completion Assistant

The feature is activated in **Text** mode in the following situations:

- After you press the **<** character when inserting an element, it is automatically activated after a short delay. You can adjust the activation delay with the ***Activation delay of the proposals window (ms)** option* from the **Content Completion** preferences page.
- After typing a partial element or attribute name, you can manually activate it by pressing **Ctrl + Space (Command + Space on OS X)** or **Alt + ForwardSlash (Command + Alt + ForwardSlash on OS X)**. If there is only one valid proposal at the current location, it is inserted without displaying the list of proposals.

The *Content Completion Assistant* proposes numerous item types (such as templates, variables, parameters, keys, etc.) that are defined in the current stylesheet, and in the imported and included XSLT stylesheets. The *Content Completion Assistant* also includes *code templates that can be used to quickly insert code fragments* into stylesheets.

Note: For XSL and XSD resources, the *Content Completion Assistant* collects its components starting from the *master files*. The *master files* can be defined in the project or in the associated validation scenario. For further details about the *Master Files* support go to *Defining Master Files at Project Level*.

The extension functions included in the Saxon 6.5.5 and 9.7.0.19 transformation engines are presented in the content completion list only if the Saxon namespace (*http://saxon.sf.net* for XSLT version 2.0 / 3.0 or *http://icl.com/saxon* for XSLT version 1.0) is declared and one of the following conditions is true:

- The edited file has a transformation scenario that uses as transformation engine Saxon 6.5.5 (for XSLT version 1.0), Saxon 9.7.0.19 PE or Saxon 9.7.0.19 EE (for XSLT version 2.0 / 3.0).
- The edited file has a validation scenario that uses as validation engine Saxon 6.5.5 (for version 1.0), Saxon 9.7.0.19 PE or Saxon 9.7.0.19 EE (for version 2.0 / 3.0).
- The validation engine specified in *Options* page is Saxon 6.5.5 (for version 1.0), Saxon 9.7.0.19 PE or Saxon 9.7.0.19 EE (for version 2.0 / 3.0).

Additionally. the Saxon-CE-specific extension functions and instructions are presented in the list of content completion assistance proposals only if the `http://saxonica.com/ns/interactiveXSLT` namespace is declared.

Namespace prefixes in the scope of the current context are presented at the top of the content completion assistance window to speed up the insertion into the document of prefixed elements.

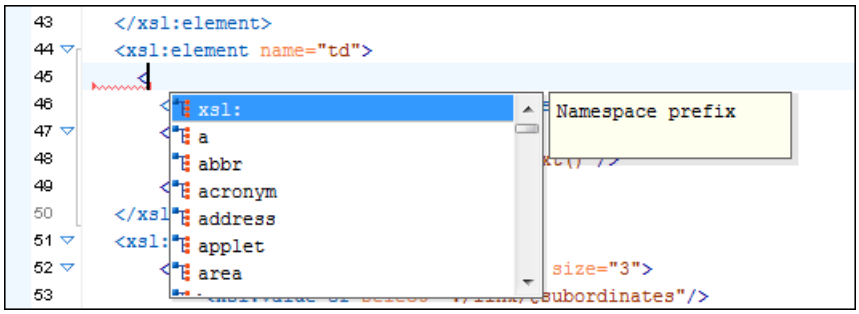

Figure 411: Namespace Prefixes in the Content Completion Assistant

For the common namespaces such as XSL namespace (`http://www.w3.org/1999/XSL/Transform`), XML Schema namespace (`http://www.w3.org/2001/XMLSchema`), or Saxon namespace (`http://icl.com/saxon` for version 1.0, `http://saxon.sf.net/` for version 2.0 / 3.0), Oxygen XML Editor provides an easy mode to declare them by proposing a prefix for these namespaces.

Content Completion in XPath Expressions

In XSLT stylesheets, the *Content Completion Assistant* provides *all the features available in the XML editor* and also adds some enhancements. In XPath expressions used in attributes of XSLT stylesheets (elements such as `match`, `select`, and `test`), the *Content Completion Assistant* offers the names of XPath and XSLT functions, XSLT axes, and user-defined functions (the name of the function and its parameters). If a transformation scenario was defined and associated to the edited stylesheet, the *Content Completion Assistant* computes and presents elements and attributes based on:

- The input XML document selected in the scenario.
- The current context in the stylesheet.

The associated document is displayed in the ***XSLT/XQuery Input*** *view*.

Content completion for XPath expressions is started:

- On XPath operators detected in one of the `match`, `select` and `test` attributes of XSLT elements: ", ', /, //, (, [, |, :, ::, $
- For attribute value templates of non-XSLT elements, that is the { character when detected as the first character of the attribute value.
- On request, if the combination **Ctrl + Space (Command + Space on OS X)** is pressed inside an edited XPath expression.

The proposals presented in the *Content Completion Assistant* are dependent on:

- The context of the current XSLT element.
- The XML document associated with the edited stylesheet in the stylesheet transformation scenario.
- The XSLT version of the stylesheet (1.0, 2.0, or 3.0).

  Note: The XSLT 3.0 content completion list of proposals includes specific elements and attributes for the 3.0 version.

For example, if the document associated with the edited stylesheet is:

```
<personnel>
    <person id="Big.Boss">
        <name>
            <family>Boss</family>
            <given>Big</given>
        </name>
        <email>chief@oxygenxml.com</email>
        <link subordinates="one.worker"/>
    </person>
    <person id="one.worker">
        <name>
            <family>Worker</family>
            <given>One</given>
        </name>
        <email>one@oxygenxml.com</email>
        <link manager="Big.Boss"/>
    </person>
```

```
</personnel>
```

If you enter an `xsl:template` element using the *Content Completion Assistant*, the following actions are triggered:

- The `match` attribute is inserted automatically.
- The cursor is placed between the quotes.
- The XPath *Content Completion Assistant* automatically displays a pop-up window with all the XSLT axes, XPath functions and elements and attributes from the XML input document that can be inserted in the current context.

The set of XPath functions depends on the XSLT version declared in the root element `xsl:stylesheet`: 1.0, 2.0, or 3.0.

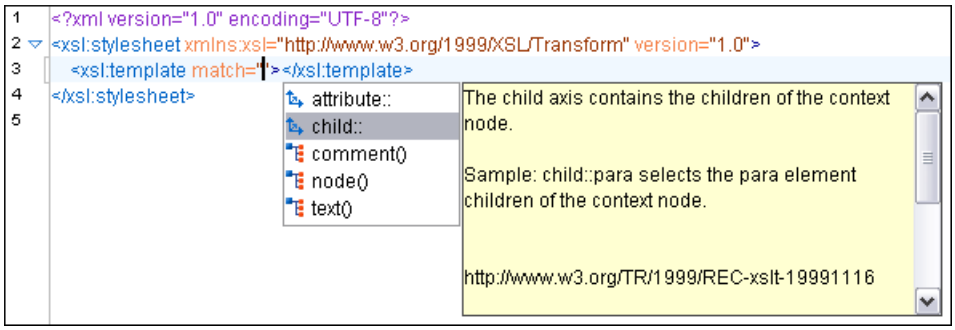

Figure 412: Content Completion in the `match` Attribute

If the cursor is inside the `select` attribute of an `xsl:for-each`, `xsl:apply-templates`, `xsl:value-of` or `xsl:copy-of` element the content completion proposals depend on the path obtained by concatenating the XPath expressions of the parent XSLT elements `xsl:template` and `xsl:for-each` as shown in the following figure:

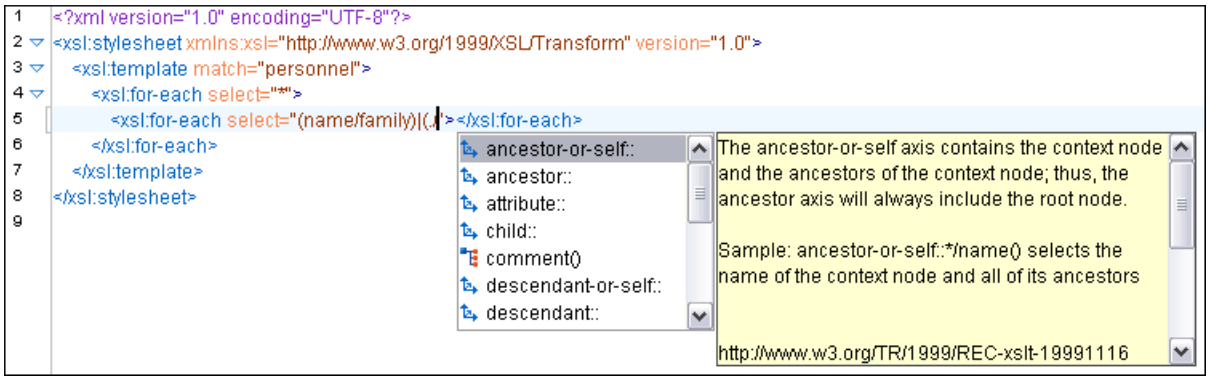

Figure 413: Content Completion in the `select` Attribute

Also XPath expressions typed in the `test` attribute of an `xsl:if` or `xsl:when` element benefit of the assistance of the content completion.

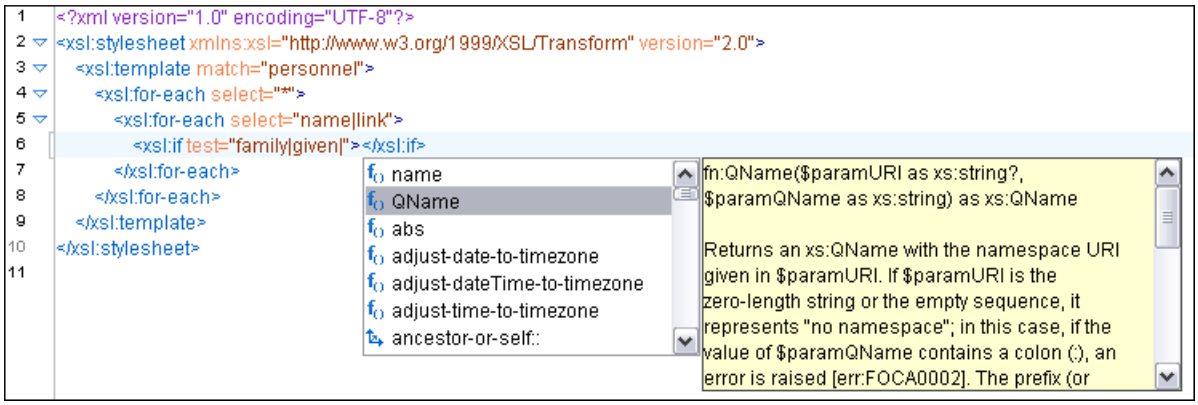

Figure 414: Content Completion in the `test` Attribute

XSLT variable references are easier to insert in XPath expressions with the help of the content completion pop-up triggered by the $ character, which signals the start of such a reference in an XPath expression.

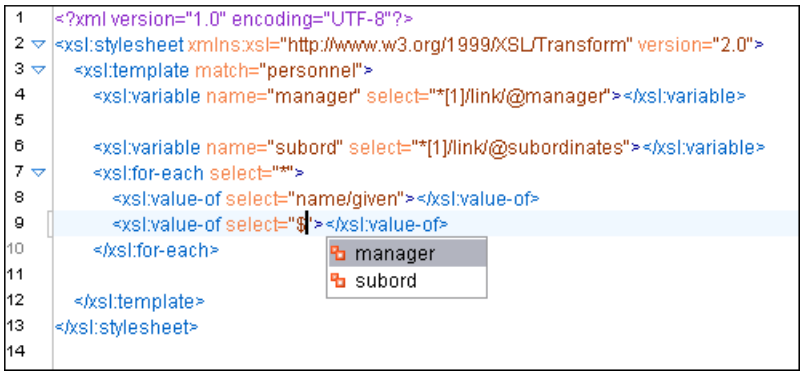

Figure 415: Content Completion in the `test` Attribute

If the { character is the first one in the value of the attribute, the same *Content Completion Assistant* is available also in attribute value templates of non-XSLT elements.

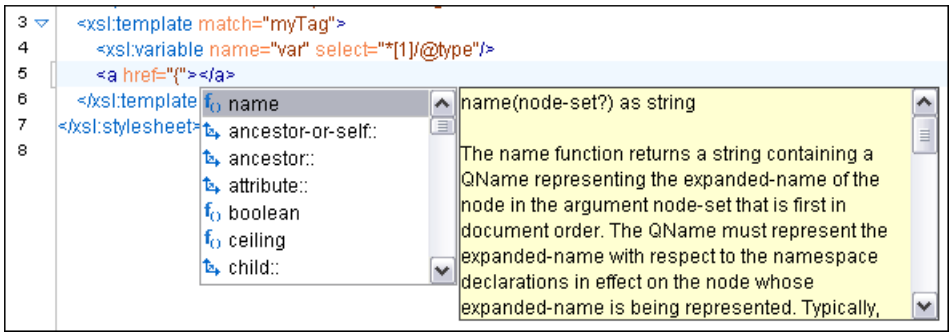

Figure 416: Content Completion in Attribute Value Templates

The time delay (*configured in the **Content Completion** preferences page*) for all content completion assistance windows is also applied for the content completion in XPath expressions.

Related Information:

Working with XPath Expressions on page 1272

Tooltip Helper for the XPath Functions Arguments

When editing the arguments of an XPath/XSLT function, Oxygen XML Editor tracks the current entered argument by displaying a tooltip containing the function signature. The currently edited argument is highlighted with a bolder font.

When moving the cursor through the expression, the tooltip is updated to reflect the argument found at the cursor position.

Examples:

If you want to concatenate the absolute values of two variables, named *v1* and *v2*:

```
<xsl:template match="/">
    <xsl:value-of select="concat(abs($v1), abs($v2))"></xsl:value-of>
</xsl:template>
```

When moving the cursor before the first `abs` function, Oxygen XML Editor identifies it as the first argument of the `concat` function. The tooltip shows in bold font the following information about the first argument:

- Its name is `$arg1`.
- Its type is `xdt:anyAtomicType`.
- It is optional (note the ? sign after the argument type).

The function also takes other arguments that have the same type and returns a `xs:string`.

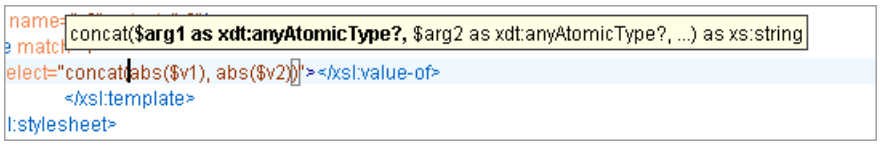

Figure 417: XPath Tooltip Helper - Identify the `concat` Function's First Argument

Moving the cursor on the first variable $v1, the editor identifies the `abs` as context function and shows its signature:

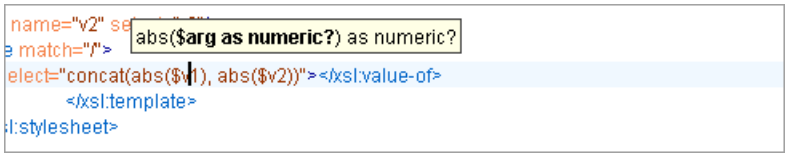

Figure 418: XPath Tooltip Helper - Identify the `abs` Function's Argument

Further, clicking the second `abs` function name, the editor detects that it represents the second argument of the `concat` function. The tooltip is repainted to display the second argument in bold font.

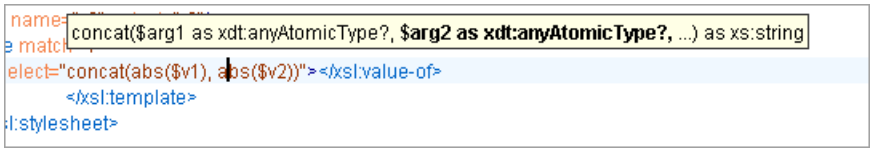

Figure 419: XPath Tooltip Helper - Identify the `concat` Function's Second Argument

Note: The tooltip helper is also available in the ***XPath Builder*** *view* and *XPath toolbar*.

Working with XPath Expressions on page 1272

Syntax Highlighting in XSLT

Oxygen XML Editor supports syntax highlighting in XSLT documents to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for XSLT files, follow these steps:

1. *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

5. Select the **XSL** tab in the **Preview** pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the ***Editor*** > ***Syntax Highlight*** > ***Elements/ Attributes by Prefix*** *preferences page*.

Related Information:

Customize Syntax Highlight colors on page 105

XSLT Outline View

The **Outline** view for XSLT stylesheets displays the list of all the components (templates, attribute-sets, character-maps, variables, functions, keys, outputs) from both the edited stylesheet and its imports or includes. For XSL and XSD resources, the **Outline** view collects its components starting from the *master files*. The master files can be defined in the project or in the associated validation scenario. For further details about the *Master Files* support go to *Defining Master Files at Project Level*.

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

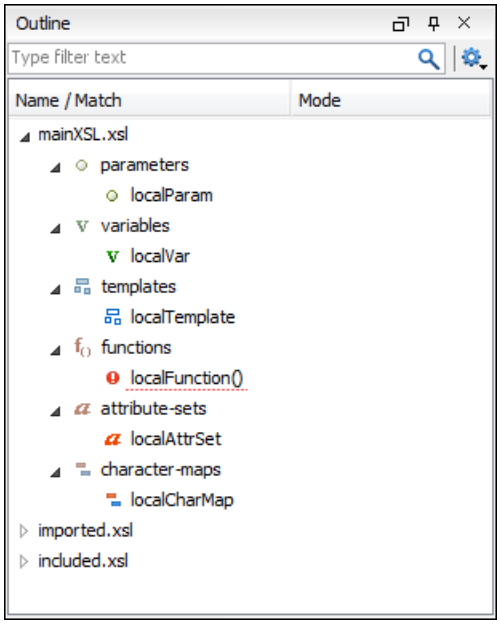

Figure 420: XSLT Outline View

The following actions are available in the **Settings** menu on the **Outline** view toolbar:

Filter returns exact matches

The text filter of the **Outline** view returns only exact matches;

Selection update on cursor move

Controls the synchronization between **Outline** view and source document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes in the XSLT editor. Selecting one of the components from the **Outline** view also selects the corresponding item in the source document.

When the **Show components** option is selected, the following actions are available:

Show XML structure

Displays the XML document structure in a tree-like structure.

Show all components

Displays all components that were collected starting from the *master file*. This option is set by default.

Show only local components

Displays the components defined in the current file only.

Group by location/type

The stylesheet components can be grouped by location and type.

When the **Show XML structure** option is selected, the following actions are available:

Show components

Switches the **Outline** view to the components display mode.

Flat presentation mode of the filtered results

When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions

Show/hide comments and processing instructions in the **Outline** view.

Show element name

Show/hide element name.

Show text

Show/hide additional text content for the displayed elements.

Show attributes

Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from *the Outline preferences panel*.

Configure displayed attributes

Displays the ***XML Structured Outline*** *preferences page*.

The following contextual menu actions are also available when the **Show components** option is selected in the **Settings** menu:

Edit Attributes

Opens a small in-place editor that allow you to edit the attributes of the selected node.

Cut

Cuts the currently selected node.

Copy

Copies the currently selected node.

Delete

Deletes the currently selected node.

Search References Ctrl + Shift + R (Command + Shift + R on OS X)

Searches all references of the item found at current cursor position in the defined scope, if any. See *Finding XSLT References and Declarations* for more details.

Search References in

Searches all references of the item found at current cursor position in the specified scope. See *Finding XSLT References and Declarations* for more details.

Component Dependencies

Opens the ***Component Dependencies*** *view* that allows you to see the dependencies for the current selected component.

Resource Hierarchy

Opens the ***Resource Hierarchy/Dependencies*** *view* that displays the hierarchy for the currently selected resource.

Resource Dependencies

Opens the ***Resource Hierarchy/Dependencies*** *view* that displays the dependencies of the currently selected resource.

Rename Component in

Renames the selected component. See *XSLT Refactoring Actions* for more details.

The following contextual menu actions are available in the **Outline** view when the **Show XML structure** option is selected in the **Settings** menu:

Append Child

Displays a list of elements that you can insert as children of the current element.

Insert Before

Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After

Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes

Opens a small in-place editor that allow you to edit the attributes of the selected node.

Toggle Comment

Comments/uncomments the currently selected element.

Search references

Searches for the references of the currently selected component.

Search references in

Searches for the references of the currently selected component in the context of a scope that you define.

Component dependencies

Opens the ***Component Dependencies*** *view* that displays the dependencies of the currently selected component.

Rename Component in

Renames the currently selected component in the context of a scope that you define.

Cut

Cuts the currently selected component.

Copy

Copies the currently selected component.

Delete

Deletes the currently selected component.

Expand More

Expands the structure of a component in the **Outline** view.

Collapse All

Collapses the structure of all the component in the **Outline** view.

The stylesheet components information is presented on two columns: the first column presents the `name` and `match` attributes, the second column the `mode` attribute. If you know the component name, match or mode, you can search it in the **Outline** view by typing one of these pieces of information in the filter text field from the top of the view or directly on the tree structure. When you type de component name, match or mode in the text field, you can switch to the tree structure using:

- Keyboard arrow keys
- **Enter** key
- **Tab** key

- **Shift-Tab** key combination

To switch from tree structure to the filter text field, you can use **Tab** and **Shift-Tab**.

Tip: The search filter is case insensitive. The following wildcards are accepted:

- ***** - any string
- **?** - any character
- **,** - patterns separator

If no wildcards are specified, the string to search is used as a partial match.

The content of the **Outline** view and the editing area are synchronized. When you select a component in the **Outline** view, its definition is highlighted in the editing area.

Oxygen XML Editor allows you to sort the components of the tree in the **Outline** view.

Note: Sorting groups in the **Outline** view is not supported.

Oxygen XML Editor has a predefined order of the groups in the **Outline** view:

- For location, the names of the files are sorted alphabetically. The file you are editing is located at the top of the list.
- For type, the order is: parameters, variables, templates, functions, set attributes, character-map.

  Note: When no grouping is available and the table is not sorted, Oxygen XML Editor sorts the components depending on their order in the document. Oxygen XML Editor also takes into account the name of the file that the components are part of.

XSLT/XQuery Input View

The structure of the XML document associated to the edited XSLT stylesheet, or the structure of the source documents of the edited XQuery is displayed in a tree form in a view called the **XSLT/XQuery Input** view. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu. The tree nodes represent the elements of the documents.

XSLT

If you click a node in the **XSLT/XQuery Input** view, the corresponding template from the stylesheet is highlighted. A node can be dragged from this view and dropped in the editor area for quickly inserting `xsl:template`, `xsl:for-each`, or other XSLT elements that have the `match/select/test` attribute already completed. The value of the attribute is the correct XPath expression that refers to the dragged tree node. This value is based on the current editing context of the drop spot.

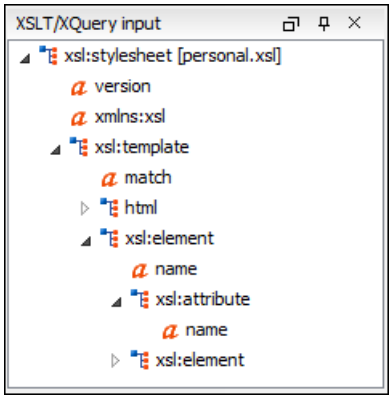

Figure 421: XSLT Input View

XSLT Example:

For the following XML document:

```
<personnel>
    <person id="Big.Boss">
        <name>
```

```
            <family>Boss</family>
            <given>Big</given>
        </name>
        <email>chief@oxygenxml.com</email>
        <link subordinates="one.worker"/>
    </person>
    <person id="one.worker">
        <name>
            <family>Worker</family>
            <given>One</given>
        </name>
        <email>one@oxygenxml.com</email>
        <link manager="Big.Boss"/>
    </person>
</personnel>
```

and the following XSLT stylesheet:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
        version="2.0">
    <xsl:template match="personnel">
        <xsl:for-each select="*">

        </xsl:for-each>
    </xsl:template>
</xsl:stylesheet>
```

if you drag the `given` element and drop it inside the `xsl:for-each` element, the following pop-up menu is displayed:

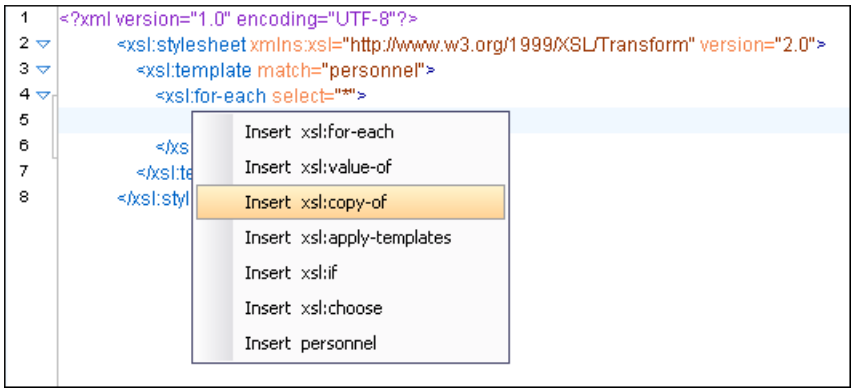

Figure 422: XSLT Input Drag and Drop Pop-up Menu

If you select **Insert xsl:copy-of** (for example), the resulting document will look like this:

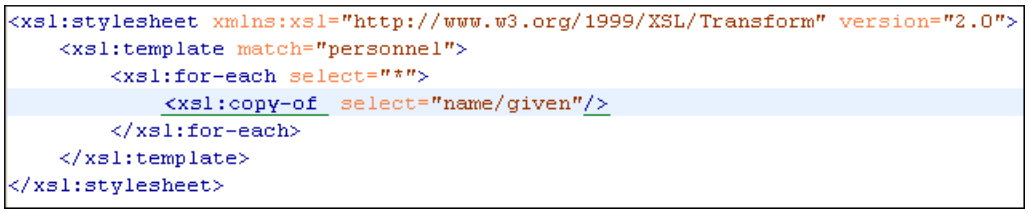

Figure 423: XSLT Input Drag and Drop Result

XQuery

You can also use the **XSLT/XQuery Input** view to drag and drop a node into the editing area to quickly insert XQuery expressions.

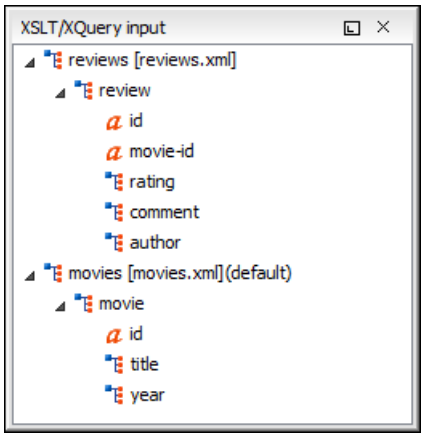

Figure 424: XQuery Input View

XQuery Example:

For the following XML documents:

```
<movies>
<movie id="1">
<title>The Green Mile</title>
<year>1999</year>
</movie>
<movie id="2">
<title>Taxi Driver</title>
<year>1976</year>
</movie>
</movies>
```

```
<reviews>
<review id="100" movie-id="1">
<rating>5</rating>
<comment>It is made after a great Stephen King book.
</comment>
<author>Paul</author>
</review>
<review id="101" movie-id="1">
<rating>3</rating>
<comment>Tom Hanks does a really nice acting.</comment>
<author>Beatrice</author>
</review>
<review id="104" movie-id="2">
<rating>4</rating>
<comment>Robert De Niro is my favorite actor.</comment>
<author>Maria</author>
</review>
</reviews>
```

and the following XQuery:

```
let $review := doc("reviews.xml")
for $movie in doc("movies.xml")/movies/movie
let $movie-id := $movie/@id
return
<movie id="{$movie/@id}">
{$movie/title}
{$movie/year}
<maxRating>
{

}
</maxRating>
</movie>
```

If you drag the **review** element and drop it between the braces, the following pop-up menu is displayed:

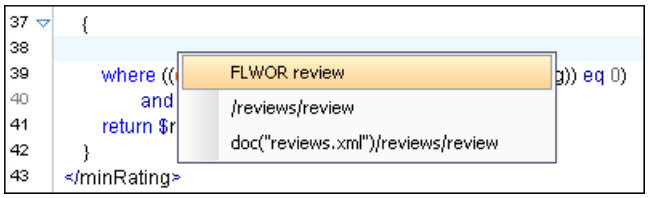

Figure 425: XQuery Input Drag and Drop Pop-up Menu

Select **FLWOR review**, the resulting document will look like this:

```
37      {
38          for $review in doc("reviews.xml")/reviews/review
39          return
40          where ((compare($rev/rating/text(), string($minRating)) eq 0)
41                  and ($rev/@movie-id = $movie/@id))
42          return $rev/author
43      }
```

Figure 426: XQuery Input Drag and Drop Result

XSLT Resource Hierarchy/Dependencies View

The **Resource Hierarchy/Dependencies** view allows you to see the hierarchy/dependencies for a stylesheet. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

If you want to see the hierarchy of a stylesheet, select the desired stylesheet in the ***Project*** *view* and choose **Resource Hierarchy** from the contextual menu.

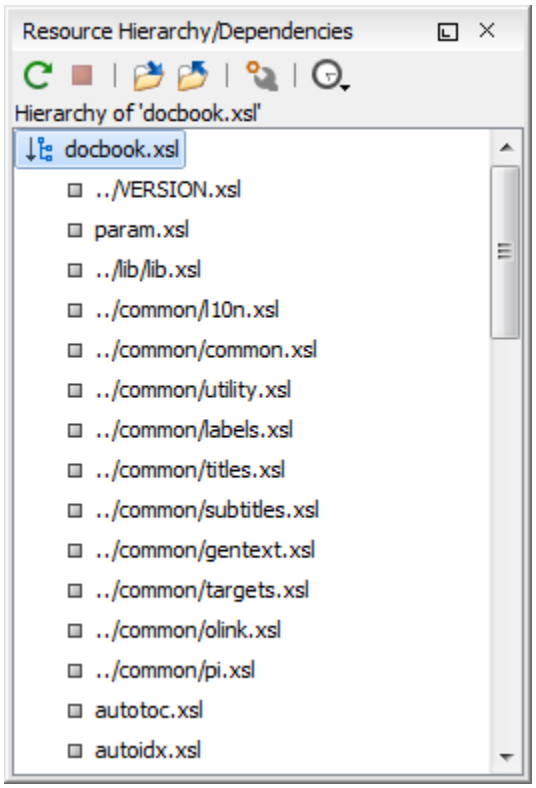

Figure 427: Resource Hierarchy/Dependencies View - Hierarchy for `docbook.xsl`

If you want to see the dependencies of a stylesheet, select the desired stylesheet in the ***Project*** *view* and choose **Resource Dependencies** from the contextual menu.

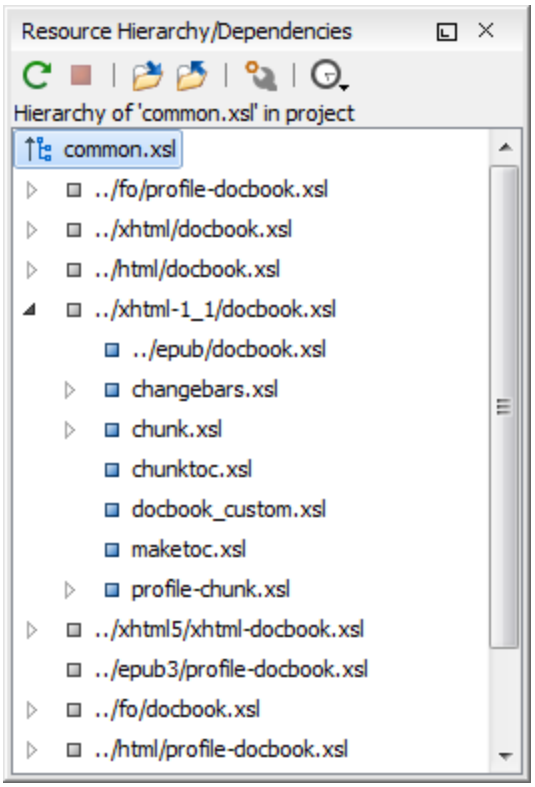

Figure 428: Resource Hierarchy/Dependencies View - Dependencies for `common.xsl`

The following actions are available in the **Resource Hierarchy/Dependencies** view:

Refresh

Refreshes the Hierarchy/Dependencies structure.

Stop

Stops the hierarchy/dependencies computing.

Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

Renames the selected resource.

Show Resource Hierarchy

Shows the hierarchy for the selected resource.

Show Resource Dependencies

Shows the dependencies for the selected resource.

 **Add to Master Files**

Adds the currently selected resource in *the **Master Files** directory*.

Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon  .

Related Information:

Working with Modular XML Files in the Master Files Context on page 692

Search and Refactor Operations Scope on page 691

Moving/Renaming XSLT Resources

You can move and rename a resource presented in the **Resource/Hierarchy Dependencies** view, using the **Rename resource** and **Move resource** refactoring actions from the contextual menu.

When you select the **Rename** action in the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Rename resource** dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references** - Select this option to update the references to the resource you are renaming.

When you select the **Move** action from the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Move resource** dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name.

If the **Update references of the moved resource(s)** option is selected, a **Preview** option (which opens the **Preview** dialog box) is available for both actions. The **Preview** dialog box presents a list with the resources that are updated.

XSLT Component Dependencies View

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

To see the dependencies of an XSLT component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for all named components (templates, variables, parameters, attribute sets, keys, functions, outputs).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon .

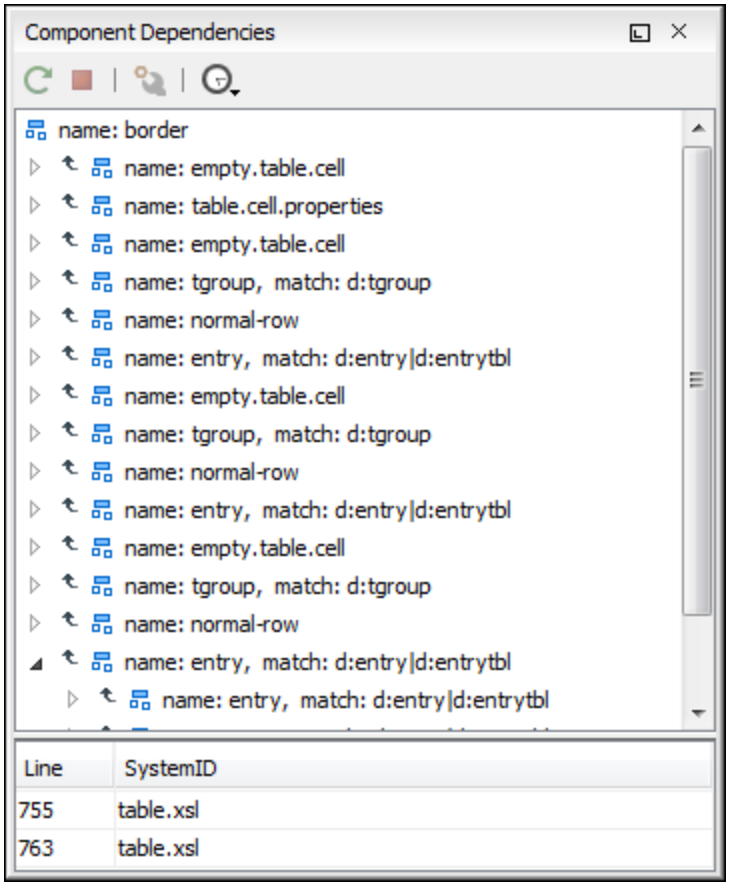

Figure 429: Component Dependencies View - Hierarchy for table.xsl

The **Component Dependencies** view includes the following toolbar actions:

Refresh

Refreshes the dependencies structure.

Stop

Stops the dependency computation.

Configure

Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

Go to First Reference

Selects the first reference of the currently selected component in the dependencies tree.

Go to Component

Shows the definition of the currently selected component in the dependencies tree.

Related Information:

Search and Refactor Operations Scope on page 691

Highlight Component Occurrences

When a component (for example variable or named template) is found at current cursor position, Oxygen XML Editor performs a search over the entire document to find the component declaration and all its references. When found, they are highlighted both in the document and in the stripe bar, at the right side of the document.

Note: Oxygen XML Editor also supports occurrences highlight for template modes.

Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected and a new search is performed. All occurrences are removed when you start to edit the document.

This feature is enabled by default. To configure it, *open the **Preferences** dialog box **(Options > Preferences)*** and go to **Editor** > **Mark Occurrences**. A search can also be triggered with the **Search** > **Search Occurrences in File (Ctrl + Shift + U (Command + Shift + U on OS X))** contextual menu action. Matches are displayed in separate tabs of the ***Results** view*.

Finding XSLT References and Declarations

The following search actions related with XSLT references and declarations are available from the **Search** submenu of the contextual menu and from the **Document** > **References** menu:

- **Search References** - Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined but the currently edited resource is not part of the range of determined resources, a warning dialog box is displayed that allows you to define another search scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify when a scope is defined.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope, if any. If a scope is defined but the current edited resource is not part of the range of resources determined by this scope, a warning dialog box is displayed that allows you to define another search scope.
- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when a scope is defined.
- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the **Document** > **Schema** menu:

- **Go to Definition** - Moves the cursor to the location of the definition of the current item.

  Note: You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

Related Information:

Search and Refactor Operations Scope on page 691

XSLT Stylesheet Component Documentation Support

Oxygen XML Editor offers built-in support for documenting XSLT stylesheets. If the expanded *QName* of the element has a non-null namespace URI, the `xsl:stylesheet` element may contain any element not from the XSLT namespace. Such elements are referenced as user-defined data elements. Such elements can contain the documentation for the stylesheet and its elements (top-level elements whose names are in the XSLT namespace). Oxygen XML Editor offers its own XML schema that defines such documentation elements. The schema is named `stylesheet_documentation.xsd` and can be found in *`[OXYGEN_INSTALL_DIR]`*`/frameworks/stylesheet_documentation`. The user can also specify a custom schema in *XSL Content Completion options*.

Content Completion

When content completion is invoked inside an XSLT editor by pressing **Ctrl + Space (Command + Space on OS X)**, it offers elements from the XSLT documentation schema (either the built-in one or one specified by user).

Adding Documentation Blocks

In **Text** mode, to add documentation blocks, press **Ctrl + Alt + D (Command + Alt + D on OS X)** or select **Add component documentation** from the contextual menu.

In **Author** mode, the following stylesheet documentation actions are available in the contextual menu, **Component Documentation** submenu:

- **Add component documentation** - Adds documentation blocks for the component at cursor position.
- **Paragraph** - Inserts a new documentation paragraph.
- **Bold** - Makes the selected documentation text bold.
- **Italic** - Makes the selected documentation text italic.
- **List** - Inserts a new list.
- **List Item** - Inserts a list item.
- **Reference** - Inserts a documentation reference.

If the cursor is positioned inside the `xsl:stylesheet` element context, documentation blocks are generated for all XSLT elements. If the cursor is positioned inside a specific XSLT element (such as a template or function), a documentation block is generated for that element only.

Example: Documentation Block Using Oxygen XML Editor Built-in Schema

```
<xd:doc>
  <xd:desc>
    <xd:p>Search inside parameter <xd:i>string</xd:i>
        for the last occurrence of parameter
    <xd:i>searched</xd:i>. The substring starting from the 0 position
        to the identified last occurrence will be returned.
    <xd:ref name="f:substring-after-last" type="function"
        xmlns:f="http://www.oxygenxml.com/doc/xsl/functions">See also
    </xd:ref>
    </xd:p>
  </xd:desc>
  <xd:param name="string">
    <xd:p>String to be analyzed</xd:p>
    </xd:param>
  <xd:param name="searched">
    <xd:p>Marker string. Its last occurrence will be identified</xd:p>
    </xd:param>
  <xd:return>
    <xd:p>A substring starting from the beginning of <xd:i>string</xd:i>
        to the last occurrence of <xd:i>searched</xd:i>.
        If no occurrence is found an empty string will be returned.
    </xd:p>
  </xd:return>
</xd:doc>
```

XSLT Documentation Links

Oxygen XML Editor includes support for links inside XSLT documentation blocks. Using a construct like `<xd:a docid="user-defined-id">TEXT</xd:a>` will cause the browser to scroll to the particular anchor (the defined ID) in the current document. Using a construct like `<xd:a href="http://www.my-web-site">TEXT</xd:a>` or `<xd:a href="local-file-path/filename">TEXT</xd:a>` will open the referenced link in a new tab.

Example: Documentation Links

```
<xd:doc xmlns:xd="http://www.oxygenxml.com/ns/doc/xsl" id="thisDoc">
   <xd:desc>
      <xd:p>
         <xd:ref name="test" type="variable">My test variable</xd:ref>
            <xd:a docid="thisDoc">Link to this documentation, see
the the id="thisDoc" above</xd:a>
            <xd:a docid="otherDocID" href="included.xsl">Link to
otherDocID defined in included.xsl</xd:a>
      </xd:p>
   </xd:desc>
</xd:doc>
```

XSLT Refactoring Actions

Oxygen XML Editor offers a set of actions that allow you to change the structure of an XSLT stylesheet without changing the results of running it in an XSLT transformation. Depending on the selected text, the following XSLT refactoring actions are available from the **Refactoring** submenu of the contextual menu (or from the **Document** > **Refactoring** menu):

- **Extract template** (Active only when the selection contains well-formed elements) - Extracts the selected XSLT instructions sequence into a new template. It opens a dialog box that allows you to specify the name of the new template to be created. The possible changes to perform on the document can be previewed before altering the document. After pressing OK, the template is created and the selection is replaced with a `<xsl:call-template>` instruction referencing the newly created template.

  Note: The newly created template is indented and its name is highlighted in the `<xsl:call-template>` element.
- **Extract function** - Extracts the selected XSLT instructions sequence into a new function. It opens a dialog box that allows you to specify the name of the new function. It then moves the selected lines to a newly created XSLT function and inserts a function call in the place of the selected lines. You can also use parts of an XPath expression to create the new functions.
- **Create local variable** - Creates an XSLT variable, wrapped around the selection. It opens a dialog box that allows you to specify the name of the new variable. It then wraps the selection in the variable and you can reference it at anytime in the code.
- **Move to another stylesheet** (Active only when entire components are selected) - Allows you to move one or more XSLT global components (templates, functions, or parameters) to another stylesheet. It opens a dialog box that allows you to specify where the selected components will be moved to. Follow these steps when using the dialog box:

  1. Choose whether you want to move the selected components to a new stylesheet or an existing one.
  2. If you choose to move the components to an existing one, select the destination stylesheet. Press the **Choose** button to select the destination stylesheet file. Oxygen XML Editor will automatically check if the destination stylesheet is already contained by the hierarchy of the current stylesheet. If it is not contained, choose whether or not the destination stylesheet will be referenced (imported or included) from the current stylesheet. The following options are available:
     - **Include** - The current stylesheet will use an `xsl:include` instruction to reference the destination stylesheet.
     - **Import** - The current stylesheet will use an `xsl:import` instruction to reference the destination stylesheet.
     - **None** - There will be created no relation between the current and destination stylesheets.
  3. Press the **Move** button to move the components to the destination. The moved components are highlighted in the destination stylesheet.
- **Convert attributes to xsl:attributes** - Converts the attributes from the selected element and represents each of them with an `<xsl:attribute>` instruction. For example, the following element:

  ```
  <person id="Big{test}Boss"/>
  ```

  is converted to:

  ```
  <person>
      <xsl:attribute name="id">
          <xsl:text>Big</xsl:text>
          <xsl:value-of select="test"/>
          <xsl:text>Boss</xsl:text>
      </xsl:attribute>
  </person>
  ```
- **Convert xsl:if into xsl:choose/xsl:when** - Converts one or more `xsl:if` element blocks into one or more `xsl:when` blocks surrounded by an `xsl:choose` element. If it is invoked on a selection, the selection must contain a well-formed fragment. If there is no selection, the `xsl:if` element that surrounds the content at the current cursor position is converted.

For example, the following block:

```
<xsl:if test="a">
  <!-- XSLT code -->
</xsl:if>
```

is converted to:

```
<xsl:choose>
    <xsl:when test="a">
        <!-- XSLT code -->
    </xsl:when>
    <xsl:otherwise>
        |
    </xsl:otherwise>
</xsl:choose>
```

(where the | character is the current cursor position)

- **Convert xsl:choose/xsl:when into xsl:if** - Converts each `xsl:when` block into an `xsl:if` block. For the *otherwise* branch, it also adds an *and* statement to each negated form of the conditions. For example, the following block:

```
<xsl:choose>
    <xsl:when test="c1">
        <!-- XSLT statement 1 -->
    </xsl:when>
    <xsl:when test="c2">
        <!-- XSLT statement 2 -->
    </xsl:when>
    <xsl:when test="c3">
        <!-- XSLT statement 3 -->
    </xsl:when>
    <xsl:otherwise>
        <!-- XSLT "otherwise" statement-->
    </xsl:otherwise>
</xsl:choose>
```

is converted to:

```
<xsl:if test="c1">
    <!-- XSLT statement 1 -->
</xsl:if>
<xsl:if test="c2">
    <!-- XSLT statement 2 -->
</xsl:if>
<xsl:if test="c3">
    <!-- XSLT statement 3 -->
</xsl:if>
<xsl:if test="not(c1) and not(c2) and not(c3)">
    <!-- XSLT "otherwise" statement-->
</xsl:if>
```

- **Extract local variable** (Active on a selection made inside an attribute that contains an XPath expression) - Allows you to create a new local variable by extracting the selected XPath expression. After creating the new local variable before the current element, Oxygen XML Editor allows you to edit the name of the variable.
- **Extract global variable** (Active on a selection made inside an attribute that contains an XPath expression) - Allows you to create a new global variable by extracting the selected XPath expression. After creating the new global variable, Oxygen XML Editor allows you to edit the name of the variable.

  Note: Oxygen XML Editor checks if the selected expression depends on local variables or parameters that are not available in the global context where the new variable is created.
- **Extract template parameter** (Active on a selection made inside an attribute that contains an XPath expression) - Allows you to create a new template parameter by extracting the selected XPath expression. After creating the new parameter, Oxygen XML Editor allows you to edit the name of the parameter.
- **Extract global parameter** (Active on a selection made inside an attribute that contains an XPath expression) - Allows you to create a new global parameter by extracting the selected XPath expression. After creating the new parameter, Oxygen XML Editor allows you to edit the name of the parameter.

  Note: Oxygen XML Editor checks if the selected expression depends on local variables or parameters that are not available in the global context where the new parameter is created.
- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at

the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.

- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

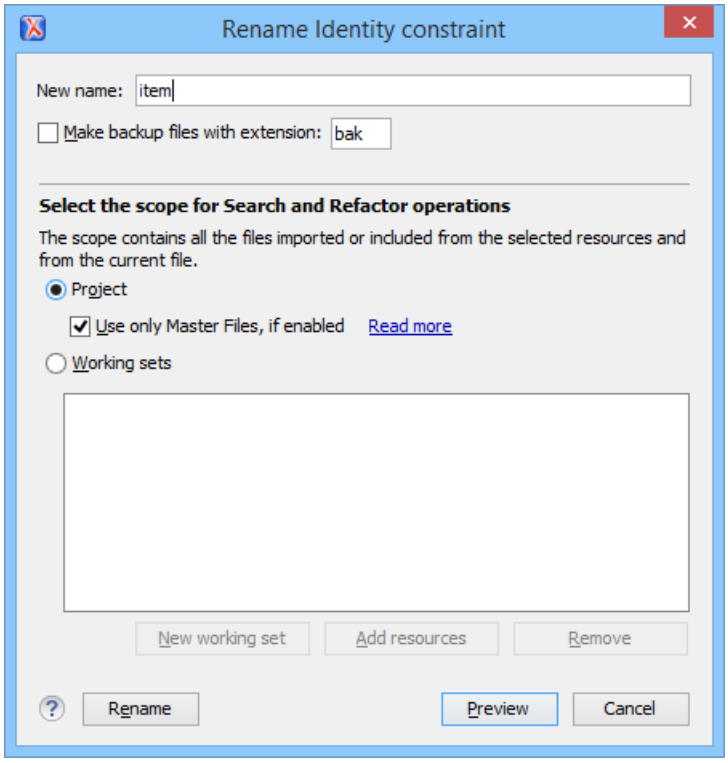

Figure 430: Rename Identity Constraint Dialog Box

Note: Many of these refactoring actions are also proposed by the *Quick Assist support*.

For more information about XSLT refactoring, watch our video demonstration:

XSLT Quick Assist Support

The *Quick Assist support* helps you to rapidly access search and refactoring actions. If one or more actions are available in the current context, they are accessible via a yellow bulb help ( ) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the *Quick Assist* menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

Two categories of actions are available in the *Quick Assist* menu:

- Actions available on a selection made inside an attribute that contains an XPath expression:

  Extract template

  Extracts the selected XSLT instructions sequence into a new template.

  Move to another stylesheet

  Allows you to move one or more XSLT global components (templates, functions, or parameters) to another stylesheet.

  Extract local variable

  Allows you to create a new local variable by extracting the selected XPath expression.

  Extract global variable

  Allows you to create a new global variable by extracting the selected XPath expression.

Extract template parameter

Allows you to create a new template parameter by extracting the selected XPath expression.

Extract global parameter

Allows you to create a new global parameter by extracting the selected XPath expression.

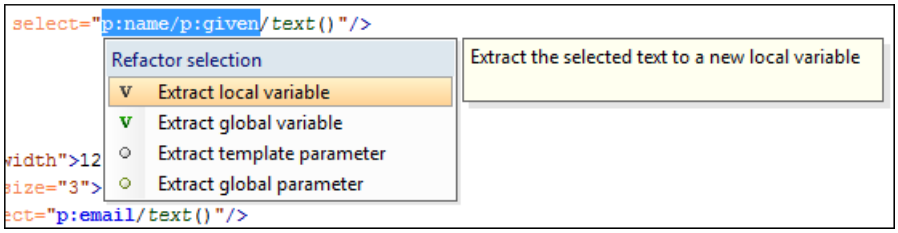

Figure 431: XSLT Quick Assist Support - Refactoring Actions

- Actions available when the cursor is positioned over the name of a component:

Rename Component in

Renames the component and all its dependencies.

Search Declarations

Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

Search References

Searches all references of the component in a predefined scope.

Component Dependencies

Searches the component dependencies in a predefined scope.

Change Scope

Configures the scope that will be used for future search or refactor operations.

Rename Component

Allows you to rename the current component in-place.

Search Occurrences

Searches all occurrences of the component within the current file.

Search and Refactor Operations Scope on page 691

XSLT Unit Test (XSpec)

XSpec is a behavior driven development (BDD) *framework* for XSLT and XQuery. XSpec consists of a syntax for describing the behavior of your XSLT or XQuery code, and some code that enables you to test your code against those descriptions.

Creating an XSLT Unit Test

To create an XSLT Unit Test, go to **File** > **New** > **XSLT Unit Test**. You can also create an XSLT Unit Test from the contextual menu of an XSL file in the ***Project*** *view*. Oxygen XML Editor allows you to customize the XSpec document when you create it. In the customization dialog box, you can enter the path to an XSL document or to a master XSL document.

When you create an XSpec document based on an XSL document, Oxygen XML Editor uses information from the validation and transformation scenarios associated with the XSL file. From the transformation scenario Oxygen XML Editor uses extensions and properties of Saxon 9.7.0.19, improving the Ant scenario associated with the XSpec document.

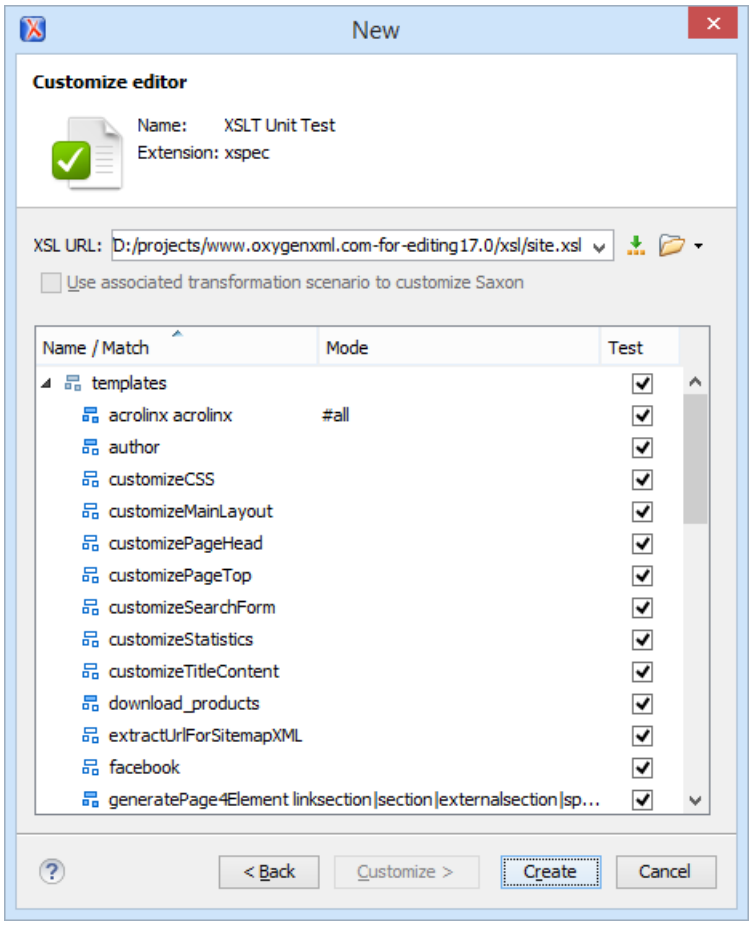

Figure 433: New XSLT Unit Test Wizard

Running an XSLT Unit Test

To run an XSLT Unit Test, open the XSpec file in an editor and click **Apply Transformation Scenario(s)** on the main toolbar. This will run the built-in **XSpec for XSLT** transformation scenario that is defined in the XSpec *framework*.

Testing a Stylesheet

An XSpec file contains one or more test scenarios. You can test a stylesheet in one of the following ways:

- Test an entire stylesheet.

  Testing is performed in a certain context. You can define a context as follows:

  - Inline context, building the test based on a string.

    ```
    <x:scenario label="when processing a para element">
        <x:context>
            <para>...</para>
        </x:context>
        ...
    </x:scenario>
    ```

  - Based on an external file, or on a part of an external file extracted with an XPath expression.

    ```
    <x:scenario label="when processing a para element">
        <x:context href="source/test.xml" select="/doc/body/p[1]" />
        ...
    </x:scenario>
    ```

- Test a function.

  ```
  <x:scenario label="when capitalising a string">
    <x:call function="eg:capital-case">
      <x:param select="'an example string'" />
      <x:param select="true()" />
    </x:call>
    ...
  </x:scenario>
  ```

- Test a template with a name.

  ```
  <x:scenario label="when creating a table">
    <x:call template="createTable">
      <x:param name="nodes">
        <value>A</value>
        <value>B</value>
      </x:param>
      <x:param name="cols" select="2" />
    </x:call>
  </x:scenario>
  ```

You can reference test files between each other, which allows you to define a suite of tests. For further details about test scenarios, go to *https://github.com/expath/xspec/wiki/Writing-Scenarios*.

Adding a Catalog to an XSpec Transformation

If your XSLT needs a catalog, you can add one to the XSpec transformation by doing one of the following:

- If you are using a *project* in Oxygen XML Editor, create a `catalog.xml` file in the project directory. This catalog will then be loaded automatically.
- *Edit* the **XSpec for XSLT** transformation scenario, go to the ***Parameters** tab*, and set the value of the `catalog` parameter to the location of your catalog file.

Generating Documentation for an XSLT Stylesheet

You can use Oxygen XML Editor to generate detailed documentation in HTML format for the elements (top-level elements whose names are in the XSLT namespace) of an XSLT stylesheet. You can select what XSLT elements to include in the generated documentation and also the level of details to present for each of them. The elements are hyperlinked. To generate documentation in a *custom output format*, you can edit the XSLT stylesheet used to generate the documentation, or create your own stylesheet.

To open the **XSLT Stylesheet Documentation** dialog box, select **XSLT Stylesheet Documentation** from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project** view*.

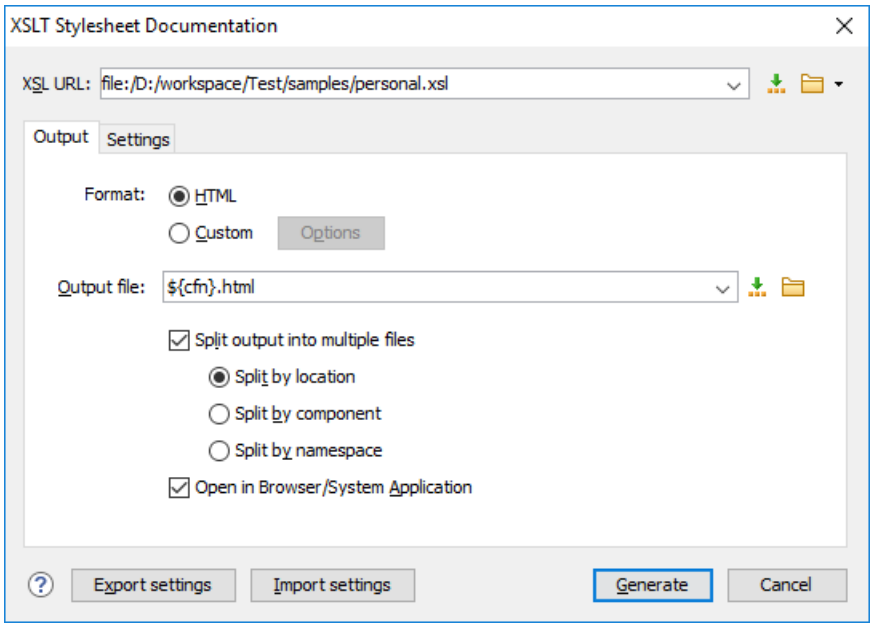

Figure 434: XSLT Stylesheet Documentation Dialog Box

The **XSL URL** field of the dialog box must contain the full path to the XSL Stylesheet file you want to generate documentation for. The stylesheet may be a local or a remote file. You can specify the path to the stylesheet by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in *HTML output format*.
  - **Custom** - The documentation is generated in a *custom output format*, allowing you to control the output. Click the **Options** button to open a ***Custom format options** dialog box* where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.
- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large XSLT stylesheets, choosing another split criterion may generate smaller output files, providing faster documentation browsing. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

  Note: To set the browser or system application that will be used, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.

Settings Tab

When you generate documentation for an XSLT stylesheet you can choose what XSLT elements to include in the output (templates, functions, global parameters, global variables, attribute sets, character maps, keys, decimal formats, output formats, XSLT elements from referenced stylesheets) and the details to include in the documentation.

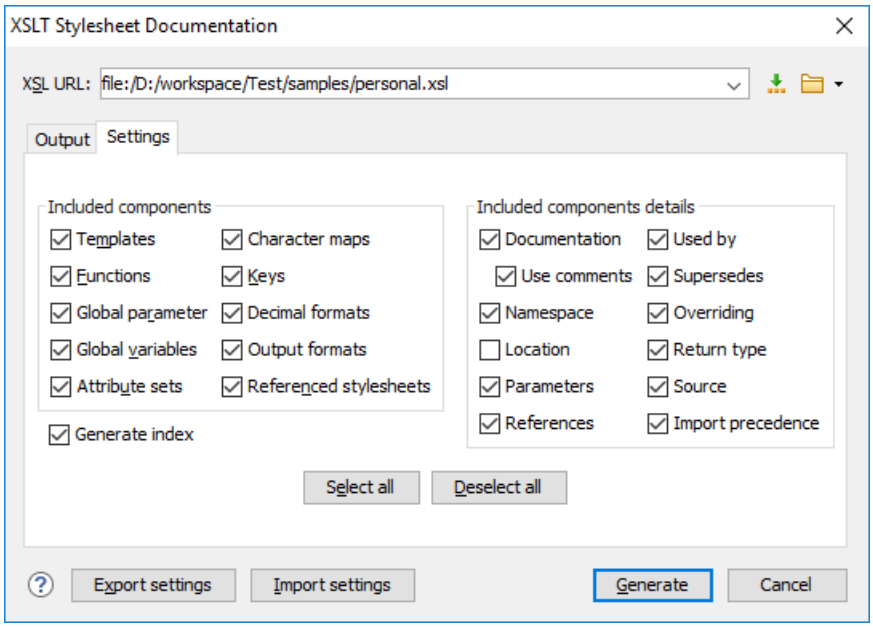

Figure 435: Settings Tab of the XSLT Stylesheet Documentation Dialog Box

The **Settings** tab allows you to choose whether or not to include the following components: **Templates**, **Functions**, **Global parameters**, **Global variables**, **Attribute sets**, **Character maps**, **Keys**, **Decimal formats**, **Output formats**, **Referenced stylesheets**.

You can choose whether or not to include the following other details:

- **Documentation** - Shows the documentation for each XSLT element. For HTML format, the user-defined data elements that are recognized and transformed in documentation blocks of the XSLT elements they precede, are the ones from the following schemas:
  - Oxygen XML Editor built-in XSLT documentation schema.
  - A subset of DocBook 5 elements. The recognized elements are: *section*, *sect1* to *sect5*, *emphasis*, *title*, *ulink*, *programlisting*, *para*, *orderedlist*, *itemizedlist*.
  - A subset of DITA elements. The recognized elements are: *concept*, *topic*, *task*, *codeblock*, *p*, *b*, *i*, *ul*, *ol*, *pre*, *sl*, *sli*, *step*, *steps*, *li*, *title*, *xref*.
  - Full XHTML 1.0 support.
  - XSLStyle documentation environment. XSLStyle uses DocBook or DITA languages inside its own user-defined data elements. The supported DocBook and DITA elements are the ones mentioned above.
  - DOXSL documentation *framework*. Supported elements are : *codefrag*, *description*, *para*, *docContent*, *documentation*, *parameter*, *function*, *docSchema*, *link*, *list*, *listitem*, *module*, *parameter*, *template*, *attribute-set*;

    Other XSLT documentation blocks that are not recognized will just be serialized inside an HTML *pre* element. You can change this behavior by using a *custom format* instead of the built-in *HTML format* and providing your own XSLT stylesheets.
- **Use comments** - Controls whether or not the comments that precede an XSLT element is treated as documentation for the element they precede. Comments that precede or succeed the *xsl:stylesheet* element, are treated as documentation for the whole stylesheet. Note that comments that precede an import or include directive are not collected as documentation for the imported/included module. Also, comments from within the body of the XSLT elements are not collected at all.
- **Namespace** - Shows the namespace for named XSLT elements.
- **Location** - Shows the stylesheet location for each XSLT element.
- **Parameters** - Shows parameters of templates and functions.
- **References** - Shows the named XSLT elements that are referenced from within an element.
- **Used by** - Shows the list of all the XSLT elements that reference the current named element.
- **Supersedes** - Shows the list of all the XSLT elements that are superseded the current element.

- **Overriding** - Shows the list of all the XSLT elements that override the current element.
- **Return type** - Shows the return type of the function.
- **Source** - Shows the text stylesheet source for each XSLT element.
- **Import precedence** - Shows the computed import precedence as declared in the XSL transformation specifications.
- **Generate index** - Creates an index with all the XSLT elements included in the documentation.

Export settings - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same *documentation from the command-line interface*.)

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the XSLT documentation.

Related Information:

XSLT Stylesheet Component Documentation Support on page 742

Generate XSLT Documentation in HTML Format

When using the *XSLT Stylesheet Documentation dialog box* to generate XSLT documentation in HTML format, it is presented in a visual diagram style with various sections, hyperlinks, and options.

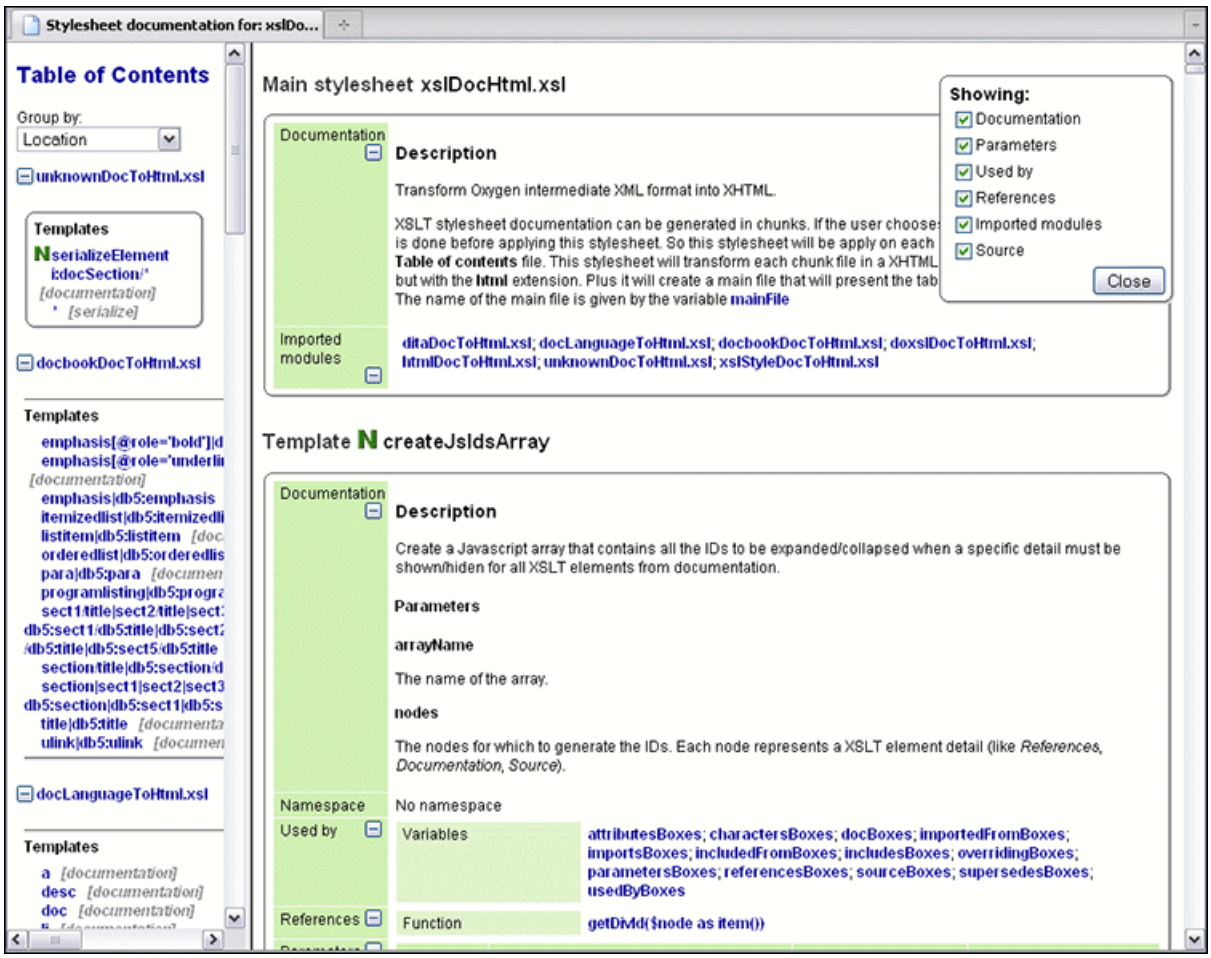

Figure 436: XSLT Stylesheet Documentation Example

The generated documentation includes the following:

- Table of Contents - You can group the contents by namespace, location, or component type. The XSLT elements from each group are sorted alphabetically (named templates are presented first and the `match` ones second).
- Information about main, imported, and included stylesheets. This information consists of:
  - XSLT modules included or imported by the current stylesheet.

- The XSLT stylesheets where the current stylesheet is imported or included.
- The stylesheet location.

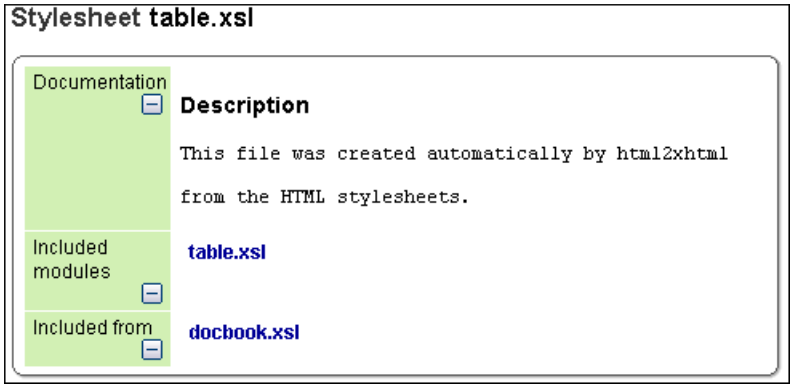

Figure 437: Information About an XSLT Stylesheet

If you choose to split the output into multiple files, the table of contents is displayed in the left frame. The contents are grouped using the same criteria as the split.

After the documentation is generated, you can collapse or expand details for some stylesheet XSLT elements by using the **Showing** options or the **Collapse** or **Expand** buttons.

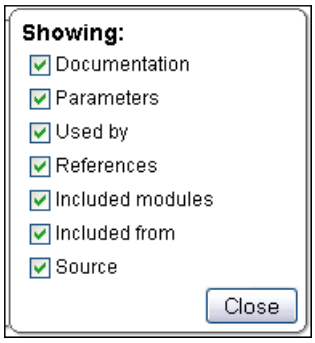

Figure 438: Showing Options

For each element included in the documentation, the section presents the element type followed by the element name (value of the `name` or `match` attribute for match templates).

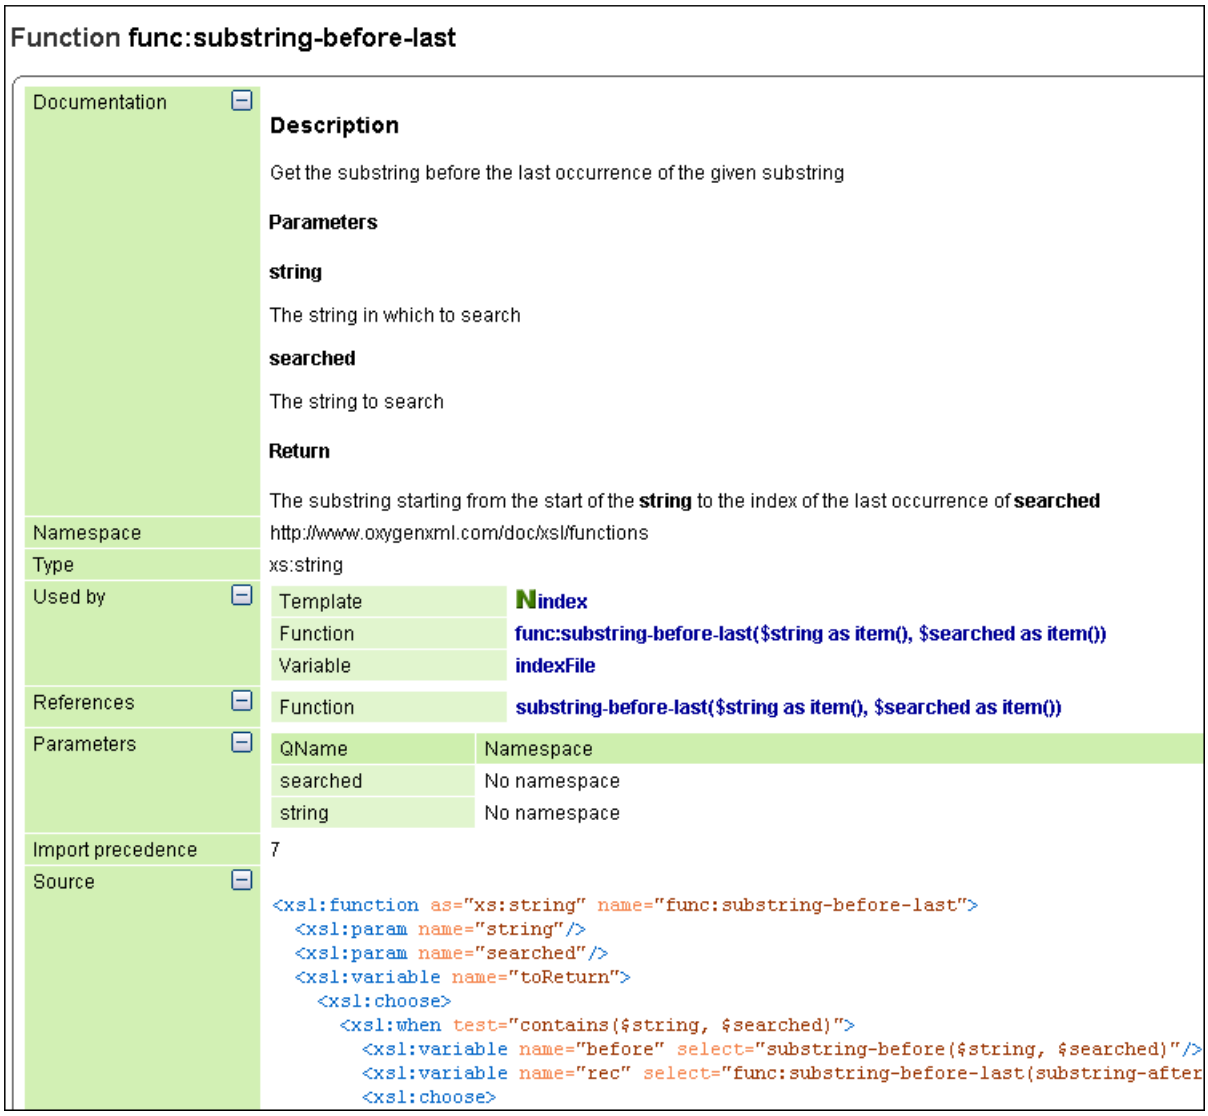

Figure 439: Documentation for an XSLT Element

Generate XSLT Documentation in a Custom Format

XSLT stylesheet documentation can be also generated in a custom format. You must write your custom stylesheet based on the schema `xslDocSchema.xsd` from *`[OXYGEN_INSTALL_DIR]`*`/frameworks/stylesheet_documentation`. You can create a custom format starting from one of the stylesheets used in the predefined HTML, PDF, and DocBook formats. These stylesheets are available in *`[OXYGEN_INSTALL_DIR]`*`/frameworks/stylesheet_documentation/xsl`.

To generate XSLT documentation in a custom format:

1. Select **Tools** > **Generate Documentation** > **XSLT Stylesheet Documentation** to open the *XSLT Stylesheet Documentation dialog box*.
2. Select **Custom** for the **Format** and click the **Options** button.
3. In this next dialog box, specify your own stylesheet to transform the intermediary XML generated in the documentation process.
4. You can also choose to copy additional resources into the output folder or choose whether or not to keep the intermediate XML files created during the documentation process.
5. Click **OK** to close this dialog box and then click **Generate**.

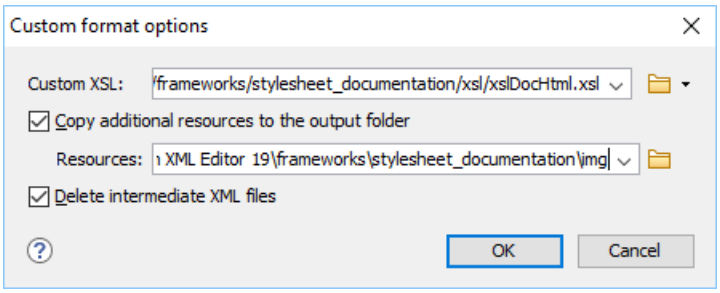

Figure 440: Custom Format Options Dialog Box

Generating XSLT Documentation From the Command-Line Interface

You can export the settings of the **XSLT Stylesheet Documentation** dialog box to an XML file by pressing the **Export settings** button. With the exported settings file, you can generate the same documentation from the command line by running the script `stylesheetDocumentation.bat` (on Windows) / `stylesheetDocumentation.sh` (on OS X / Linux) located in the Oxygen XML Editor installation folder. The script can be integrated in an external batch process launched from the command-line interface.

The command-line parameter of the script is the relative path to the exported XML settings file. The files that are specified with relative paths in the exported XML settings are resolved relative to the script directory.

Example:

```
<serialized>
    <map>
        <entry>
            <String xml:space="preserve">xsd.documentation.options</String>
            <xsdDocumentationOptions>
                <field name="outputFile">
                    <String xml:space="preserve">${cfn}.html</String>
                </field>
                <field name="splitMethod">
                    <Integer xml:space="preserve">1</Integer>
                </field>
                <field name="openOutputInBrowser">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="format">
                    <Integer xml:space="preserve">1</Integer>
                </field>
                <field name="customXSL">
                    <null/>
                </field>
                <field name="deleteXMLFiles">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeIndex">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeGlobalElements">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeGlobalAttributes">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeLocalElements">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeLocalAttributes">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeSimpleTypes">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeComplexTypes">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeGroups">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeAttributesGroups">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeRedefines">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="includeReferencedSchemas">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="detailsDiagram">
                    <Boolean xml:space="preserve">true</Boolean>
```

```
                </field>
                <field name="detailsNamespace">
                    <Boolean xml:space="preserve">true</Boolean>
                </field>
                <field name="detailsLocation">

        </entry>
    </map>
</serialized>
```

Compiling an XSL Stylesheet for Saxon

As of Saxon 9.7, it is possible to export a compiled form of a stylesheet as an XML file (called a *stylesheet export file* or SEF). Oxygen XML Editor includes a simple tool called **Compile XSL Stylesheet for Saxon** (found in the **Tools** menu) that does this for you.

Use-Cases for a Stylesheet Export File (SEF)

- **Use Saxon-JS to run transformations in a browser** - A *stylesheet export file* (SEF) is needed if you want to use the *Saxon-JS product* to run transformations in a browser, as in the following example:

```
<script type="text/javascript" src="SaxonJS/SaxonJS.min.js"></script>
<script>
    window.onload = function() {
      SaxonJS.transform({
         stylesheetLocation: "books.sef",
         sourceLocation: "books.xml"
         });
    }
</script>
```

- **Use SEF to run transformations in Oxygen XML Editor** - You can also use a *stylesheet export file* (SEF) in Oxygen XML Editor to apply an XSLT transformation over an XML file. This requires **Saxon-EE** or **Saxon-PE** versions of the Saxon product and you must select one of those two versions for the ***Target*** *when you configure the SEF file*. When configuring the XSLT transformation, you will specify the SEF file in the ***XSL URL*** *field*.

Compiling an SEF File

The **Compile XSL Stylesheet for Saxon** tool can be found in the **Tools** menu and it compiles a specified stylesheet as an XML file (*stylesheet export file* with a file extension of `.sef`).

Selecting this tool opens the **Compile XSL Stylesheet for Saxon** dialog box that allows you to configure some options for conversion.

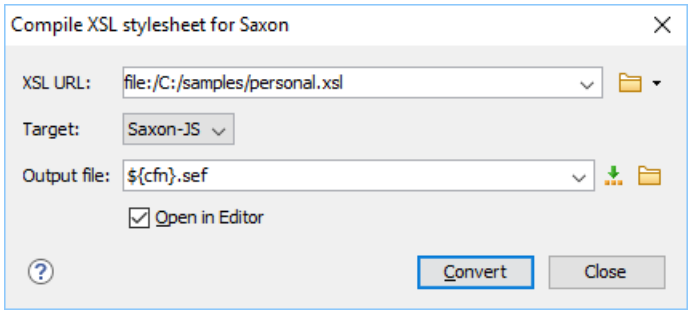

Figure 441: Compile XSL Stylesheet for Saxon Dialog Box

This dialog box includes the following options:

XSL URL

Allows you to select URL of the source XSL stylesheet. You can specify the URL by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down list.

Target

Allows you to select the type of Saxon product that the export file will be used with. You can choose **Saxon-JS**, **Saxon-EE**, **Saxon-PE**, or **Saxon-HE**.

Output file

You can specify the path where the output file will be saved by entering it in the text field, using the **Insert Editor Variables** button, or using the browsing tool button.

Open in Editor

Select this option to open the resulting *stylesheet export file* in the main Oxygen XML Editor editing pane.

Convert

Use this button to generate the *stylesheet export file* according the options selected in this dialog box.

Editing Ant Build Files

Oxygen XML Editor includes an Ant editor that provides a variety of specialized features to assist you with creating and editing Ant build files. The editor includes some specialized views, content completion assistance, automatic validation, syntax highlighting, *Quick Assist* and *Quick Fix* support, as well as numerous common editing and search features.

Related Information:

Editing XML Documents in Text Mode on page 492

Editing Ant Build Files in the Context of Master Files

Smaller interrelated modules that define a complex Ant build file cannot be correctly edited or validated individually due to their interdependency with other modules. For example, a *target* defined in a main build file is not visible when you edit an included or imported module. Oxygen XML Editor provides support for defining the main module (or modules), allowing you to edit any of the imported/included files in the context of the larger Ant build structure.

You cat set a main Ant build file either by using the *master files support from the **Project** view*, or *a validation scenario*.

To set a *master file* using a validation scenario, add validation units that point to the main modules. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main build file. In this case, it considers the current module as the main build file.

The advantages of editing in the context of *master file* include:

- Correct validation of a module in the context of a larger build structure.
- *Content Completion Assistant* displays all components valid in the current context.
- The ***Outline** view* displays the components collected from the entire build file structure.

Validating Ant Build Files

Oxygen XML Editor performs the validation of Ant build files with the help of a built-in processor, which is largely based on the *Apache Ant* libraries. The path to these libraries can be configured in the ***Ant** preferences page*. The validation processor accesses the *parameters set in the associated Ant transformation scenario* and uses them as Ant properties when validating the current build script.

Oxygen XML Editor automatically validates Ant build files as you type. You can also validate the currently edited file by selecting the **Validate** action from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu.

Tip: To make a custom task available in the Ant validation engine, add a *JAR* file that contains the task implementation to the library directory of the built-in Ant distribution that comes bundled with Oxygen XML Editor (for example, *[OXYGEN_INSTALL_DIR]*`/tools/ant/lib` folder).

Create a Validation Scenario for Ant Build Files

If you want to customize the validation process for Ant build files, you can create a new validation scenario (or configure an existing one). For example, if you want to validate interrelated modules that define a complex Ant build file, you can specify the main Ant file by configuring a validation scenario. To create or configure a validation scenario, select **Configure Validation Scenario(s)** from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu.

Passing parameters to the Ant validation engine

Ant validation scenarios cannot be configured to accept custom Ant parameters. However, you can specify values for the parameters in your Ant document using an Ant transformation scenario:

1. Create a new *Ant transformation scenario*.
2. Edit the transformation scenario and *set all parameters* you need to pass to your Ant document.
3. Associate the new scenario with your Ant document (in the ***Configure Transformation Scenarios(s)** dialog box*). You do not need to run the transformation scenario. Every time a validation operation is triggered, the built-in validation engine uses the parameters set in the transformation scenario.

   Note: This behavior is available only for the validation scenarios that use the built-in validation engine. The custom defined validation engines do not benefit from this functionality.

Transforming Ant Build Files

Oxygen XML Editor includes a few built-in transformation scenarios that allow you to transform Ant build files. They are listed in the **Ant** section in the ***Configure Transformation Scenario(s)** dialog box*:

- **ANT** - This transformation scenario runs as an external process that executes the Ant build script with the built-in Ant distribution (*Apache Ant* version 1.8.2) that is included with Oxygen XML Editor, or optionally with a custom Ant distribution configured in the scenario.
- **ANT (with Saxon 9 EE XSLT support)** - This transformation scenario allows Ant XSLT tasks to be performed using Saxon 9 *JAR* libraries that come bundled with Oxygen XML Editor and all defined XML catalogs are also taken into account during the transformation.

Related Information:

Editing a Transformation Scenario on page 1136

Configure Transformation Scenario(s) Dialog Box on page 1138

Apply Associated Transformation Scenarios on page 1141

Ant Transformation on page 1119

This type of transformation allows you to configure the options and parameters of an Ant build script.

Ant Quick Fix Support

The Oxygen XML Editor *Quick Fix support* helps you resolve missing target reference errors that may occur when developing Ant build documents.

To activate this feature, hover over or place the cursor in the highlighted area of text where a validation error or warning occurs. If a *Quick Fix* is available for that particular error or warning, you can access the *Quick Fix* proposals with any of the following methods:

- When hovering over the error or warning, the proposals are presented in a tooltip pop-up window.
- If you place the cursor in the highlighted area where a validation error or warning occurs, a *Quick Fix* icon () is displayed in the stripe on the left side of the editor. If you click this icon, Oxygen XML Editor displays the list of available fixes.
- With the cursor placed in the highlighted area of the error or warning, you can also invoke the *Quick Fix* menu by pressing **Alt + 1 (Command + Alt + 1 on OS X)** on your keyboard.

Oxygen XML Editor provides the following types of *Quick Fixes* for Ant build files:

- **Create new target** - Creates a new target with the specified name.
- **Change reference to "targetName"** - Corrects the reference to point to an already defined target.
- **Remove target reference** - Removes the erroneous reference.

Content Completion in Ant Build Files

The list of proposals offered by the *Content Completion Assistant* in Ant build files are context-sensitive and includes proposals that are valid at the current cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

The *Content Completion Assistant* proposes various item types that are defined in the current Ant build and in the imported and included builds. The proposals include:

- Element names
- Attribute names
- Property names

  Note: In addition to the user-defined properties, the *Content Completion Assistant* offers the following values:

  - The system properties set in the Java Virtual Machine.
  - The built-in properties that Ant provides.
- Target names
- Task and type reference IDs

  Tip: To make a custom task available in the *Content Completion Assistant*, add a *JAR* file that contains the task implementation to the library directory of the built-in Ant distribution that comes bundled with Oxygen XML Editor (for example, *[OXYGEN_INSTALL_DIR]*`/tools/ant/lib` folder).

Note: For Ant resources, the proposals are collected starting from the *master files*. The *master files* can be defined in the project or in the associated validation scenario. For further details about the *Master Files* support go to *Defining Master Files at Project Level*.

Related Information:

Syntax Highlighting in Ant Files

Oxygen XML Editor supports syntax highlighting in Ant files to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for Ant build files, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **Ant Property** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Related Information:

Syntax Highlight Preferences on page 105

Ant Outline View

The **Outline** view for Ant files displays the list of all the components (properties, targets, extension points, task/type definitions and references) from both the edited Ant build file and its imported and included modules. For Ant resources, the **Outline** view collects its components starting from the *master files*. The *master files* can be defined in the project and the main build file can be specified in a validation scenario. For more details, see *Defining Master Files at Project Level*.

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

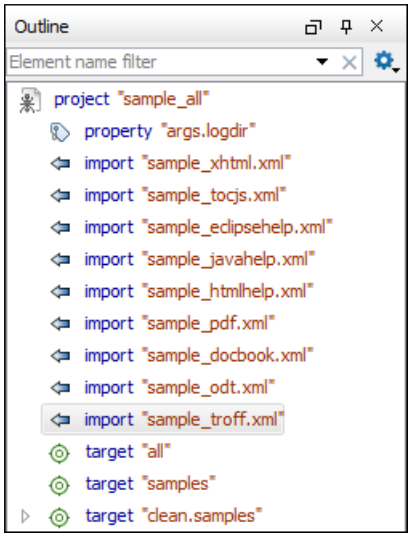

Figure 442: Ant Outline View

The following actions are available in the **Settings** menu on the Outline view toolbar:

Filter returns exact matches

The text filter of the **Outline** view returns only exact matches. By default, this filter is not selected.

Selection update on cursor move

Controls the synchronization between **Outline** view and source document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes in the Ant editor. Selecting one of the components from the outline view also selects the corresponding item in the source document.

When the **Show components** option is selected, the following actions are available:

Show XML structure

Displays the XML document structure in a tree-like manner.

Sort

Sorts the components in the **Outline** view alphabetically.

Show all components

Displays all components that were collected starting from the *master file*. This option is set by default.

Show only local components

Displays the components defined in the current file only.

Group by location/type

The build file components can be grouped by location and type.

When the **Show XML structure** option is selected, the following actions are available:

Show components
Switches the **Outline** view to the components display mode.

Flat presentation mode of the filtered results
When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions
Show/hide comments and processing instructions in the **Outline** view.

Show element name
Show/hide element name.

Show text
Show/hide additional text content for the displayed elements.

Show attributes
Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from *the Outline preferences panel*.

Configure displayed attributes
Displays the ***XML Structured Outline*** *preferences page*.

The following actions are available in the contextual menu of the **Outline** view (when the **Show XML structure** option is selected in the **Settings** menu:

Append Child
Displays a list of elements that can be inserted as children of the current element.

Insert Before
Displays a list of elements that can be inserted as siblings of the current element, before the current element.

Insert After
Displays a list of elements that can be inserted as siblings of the current element, after the current element.

Edit Attributes
Displays an in-place attribute editing window.

Toggle Comment
Comments/uncomments the currently selected element.

Search References Ctrl + Shift + R (Command + Shift + R on OS X)
Searches all references of the item found at current cursor position in the defined scope. See *Find References and Declarations of Ant Components* for more details.

Search References in
Searches all references of the item found at current cursor position in the specified scope. See *Find References and Declarations of Ant Components* for more details.

Component Dependencies
Opens the *Ant* ***Component Dependencies*** *view* that allows you to see the dependencies for the current selected component.

Rename Component in
Renames the selected component. See *Ant Refactoring Actions* for more details.

Cut, Copy, Delete
Executes the typical editing actions on the currently selected component.

Expand More

Expands recursively all sub-components of the selected component.

Collapse All

Collapses recursively all sub-components of the selected component.

You can search a component in the **Outline** view by typing its name in the filter text field at the top of the view or directly on the tree structure. When you type the component name in the text field, you can switch to the tree structure using the following:

- **Down** arrow key
- **Tab** key
- **Shift-Tab** key combination

To switch from tree structure to the filter text field, you can use **Tab** and **Shift-Tab**.

Tip: The search filter is case insensitive. The following wildcards are accepted:

- ***** - any string
- **?** - any character
- **,** - patterns separator

If no wildcards are specified, the string to search is used as a partial match (such as ***textToFind***).

The content of the **Outline** view and the editing area are synchronized. When you select a component in the **Outline** view, its definition is highlighted in the editing area.

Oxygen XML Editor has a predefined order for the groups in the **Outline** view:

- For location, the names of the files are sorted alphabetically. The file you are editing is located at the top of the list.
- For type, the order is: properties, targets, references.

  Note: When no grouping is available Oxygen XML Editor sorts the components depending on their order in the document. Oxygen XML Editor also takes into account the name of the file that the components are part of.

Ant Resource Hierarchy/Dependencies View

The **Resource Hierarchy/Dependencies** view allows you to see the hierarchy/dependencies for an Ant build file by analyzing imported or included build files. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

If you want to see the hierarchy of a build file, select it in the ***Project*** *view* and choose **Resource Hierarchy** from the contextual menu.

If you want to see the dependencies of a build file, select it in the ***Project*** *view* and choose **Resource Dependencies** from the contextual menu.

The following actions are available in the **Resource Hierarchy/Dependencies** view:

Refresh

Refreshes the Hierarchy/Dependencies structure.

Stop

Stops the hierarchy/dependencies computing.

Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

Renames the selected resource.

Show Resource Hierarchy

Shows the hierarchy for the selected resource.

Show Resource Dependencies

Shows the dependencies for the selected resource.

Add to Master Files

Adds the currently selected resource in *the **Master Files** directory*.

Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon .

Ant Component Dependencies View

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

To see the dependencies of an Ant component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for the following components: *properties*, *targets*, *extension-points*, and *references* (those that have an ID set).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon .

The **Component Dependencies** view includes the following toolbar actions:

Refresh

Refreshes the dependencies structure.

Stop

Stops the dependency computation.

Configure

Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

Go to First Reference

Selects the first reference of the currently selected component in the dependencies tree.

Go to Component

Shows the definition of the currently selected component in the dependencies tree.

Search and Refactor Operations Scope on page 691

Highlight Component Occurrences

When a component (for example *property* or *target*) is found at the current cursor position, they are highlighted in both the document and in the stripe bar at the right side of the document. Oxygen XML Editor also supports occurrences highlight for type and task references.

Customizable colors are used (one for the component definition and another one for component references). Occurrences are displayed until another component is selected and a new search is performed. All highlights are removed when you start to edit the document.

This feature is enabled by default. To configured it, *open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **Editor** > **Mark Occurrences**. If your particular type of file is not selected, you can perform this search by going to **Search** > **Search Occurrences in File** **Ctrl + Shift + U (Command + Shift + U on OS X)** in the contextual menu. Matches are displayed in separate tabs of the ***Results** view*.

Related Information:

Mark Occurrences Preferences on page 112

Find References and Declarations of Ant Components

The following search actions related to references and declarations of Ant components are available from the **Search** submenu of the contextual menu and from the **Document** > **References** menu::

- **Search References** - Searches all references of the item found at current cursor position in the defined scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify after selecting a scope for the search operation.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope.
- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when defining a new scope.
- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the **Document** > **Schema** menu:

- **Go to Definition** - Moves the cursor to the location of the definition of the current item.

  Note: You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

Related Information:

Search and Refactor Operations Scope on page 691

Ant Refactoring Actions

The following refactoring actions can be applied on *targets*, *extension-points*, *properties*, and *references* and allow you to consistently rename a component in the entire Ant build file structure. They are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document** > **Refactoring** menu:

- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.
- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

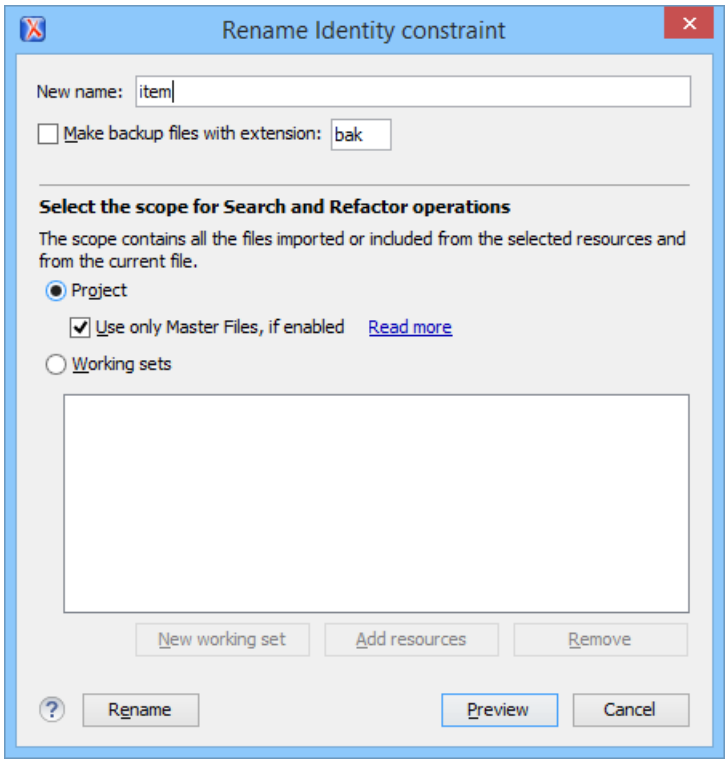

Figure 443: Rename Identity Constraint Dialog Box

Ant Quick Assist Support

The *Quick Assist support* helps you to rapidly access search and refactoring actions. If one or more actions are available in the current context, they are accessible via a yellow bulb icon ( ) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the *Quick Assist* menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

The *Quick Assist* support offers direct access to the following actions:

Rename Component in

Renames the component and all its dependencies.

Search Declarations

Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

Search References

Searches all references of the component in a predefined scope.

Component Dependencies

Searches the component dependencies in a predefined scope.

Change Scope

Configures the scope that will be used for future search or refactor operations.

Rename Component

Allows you to rename the current component in-place.

Search Occurrences

Searches all occurrences of the component within the current file.

Editing XML Schemas

An XML Schema describes the structure of an XML document and is used to validate XML document instances against it, to check that the XML instances conform to the specified requirements. If an XML instance conforms to the schema then it is said to be valid. Otherwise, it is invalid.

Oxygen XML Editor offers support for both XML Schema 1.0 and 1.1 and you can edit XML Schema files in the following editing modes:

- ***Text editing mode*** - Allows you to edit XML Schema files in a source editing mode.
- ***Grid editing mode*** - Displays XML Schema files in a structured spreadsheet-like grid.
- ***Design editing mode*** - Visual schema designer that helps you understand the structure and develop complex schemas.
- ***Author editing mode*** - The visual **Author** mode is also available for XML Schema, allowing you to visually edit the schema annotations. It presents a polished and compact view of the XML Schema, with support for links on imported/included schemas.

For information about applying and detecting schemas, see *Associating a Schema to XML Documents* on page 674.

For more information about editing XML Schemas, see our video demonstration:

Related Information:

Associating a Schema to XML Documents on page 674

Design Editing Mode (XML Schema Diagram Editor)

XML Schemas allow document designers to specify the allowed structure and content of an XML document and to check if an XML document is valid.

Oxygen XML Editor provides a simple and expressive XML Schema diagram editor (**Design** mode) for editing XML Schemas. The schema diagram helps both the content authors who want to understand a schema and schema designers who develop complex schemas.

The diagram font can be increased using the usual Oxygen XML Editor shortcuts: **(Ctrl (Meta on Mac OS) + "+")** , **(Ctrl (Meta on Mac OS)+"-")** , **(Ctrl (Meta on Mac OS) + 0)** or **(Ctrl (Meta on Mac OS) - mouse wheel)**. The whole diagram can also be zoomed with one of the predefined factors *available in the Schema preferences panel*. The same zoom factor is applied for the print and save actions.

To switch to this mode, select **Design** at the bottom of the editing area. 

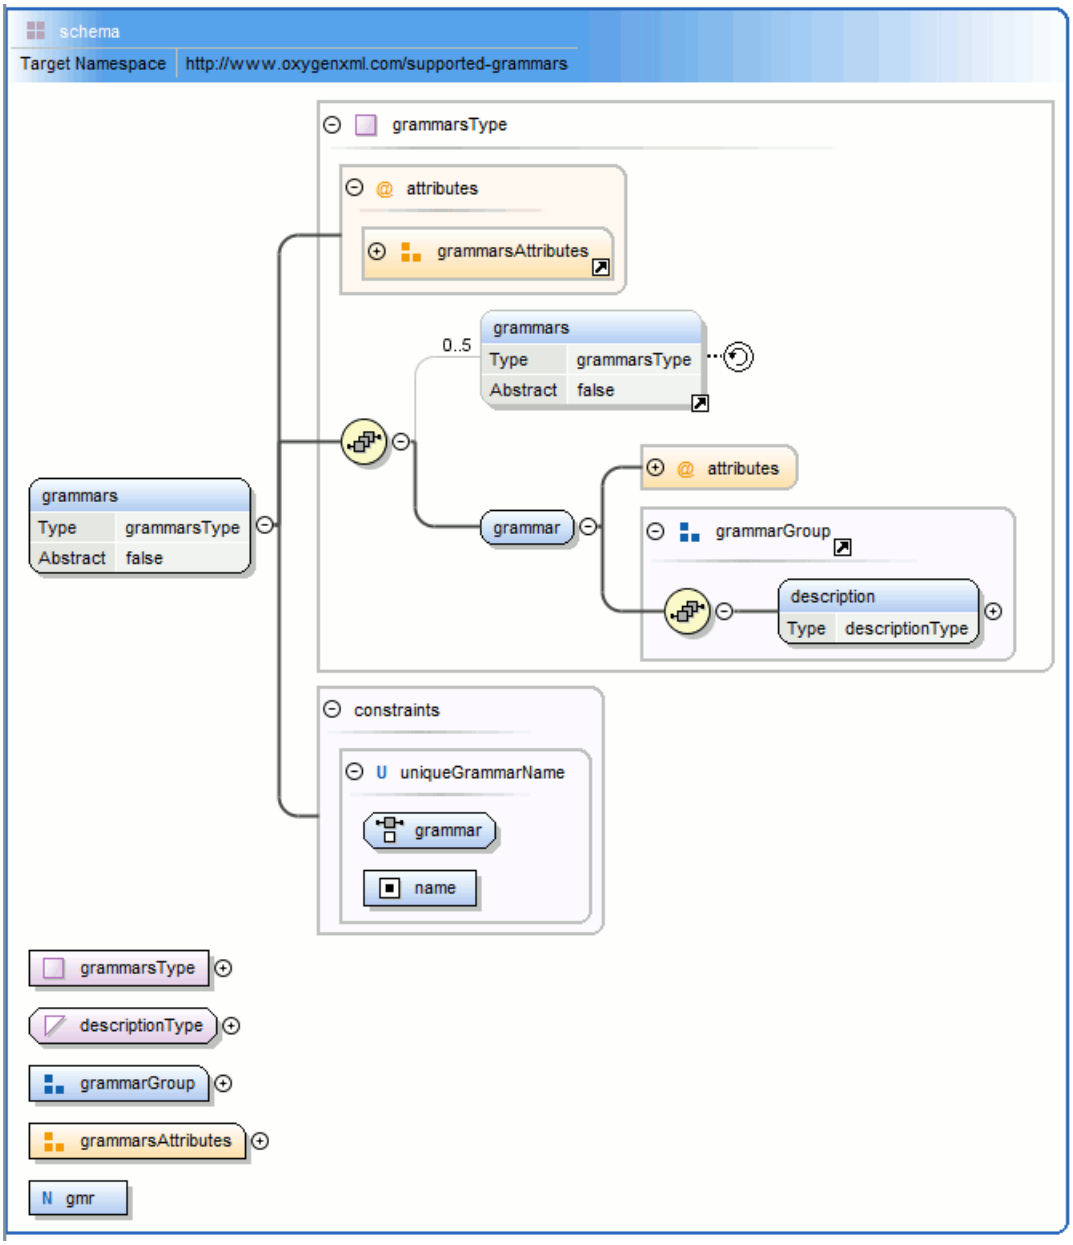

Figure 444: XML Schema Diagram

For more information about designing XML Schemas, watch our video demonstration:

Navigation in the XML Schema Design Mode

The following editing and navigation features work for all types of schema components in the XML Schema **Design** mode:

- Move/reference components in the diagram using drag-and-drop actions.
- Select consecutive components on the diagram (components from the same level) using the *Shift* key. You can also make discontinuous selections in the schema diagram using the **Ctrl (Meta on Mac OS)** key. To deselect one of the components, use **Ctrl + Single-Click (Command + Single-Click on OS X)**.
- Use the arrow keys to navigate the diagram vertically and horizontally.
- Use *Home*/*End* keys to jump to the first/last component from the same level. Use **Ctrl + Home (Command + Home on OS X)** key combination to go to the diagram root and **Ctrl + End (Command + End on OS X)** to go to the last child of the selected component.
- You can easily go back to a previously visited component while moving from left to right. The path will be preserved only if you use the left arrow key or right arrow key. For example, if the current selection is on the

second attribute from an attribute group and you press the left arrow key to jump to the attribute group, when you press the right arrow key, then the selection will be moved to the second attribute.

- Go back and forward between components viewed or edited in the diagram by selecting them in the ***Outline*** *view*:
  - **Back** (go to previous schema component).
  - **Forward** (go to next schema component).
  - **Go to Last Modification** (go to last modified schema component).
- Copy, reference, or move global components, attributes, and identity constraints to another position and from one schema to another using the **Cut/Copy** and **Paste/Paste as Reference** actions.
- Go to the definition of an element or attribute with the **Go to Definition** action.
- Search in the diagram using the *Find/Replace dialog box* or the *Quick find toolbar*. You can find/replace components only in the current file scope.
- You can expand and see the contents of the imports/includes/redefines in the diagram. In order to edit components from other schemas the schema for each component will be opened as a separate file in Oxygen XML Editor.

  Tip: If an XML Schema referenced by the current opened schema was modified on disk, the change will be detected and you will be asked to refresh the current schema contents.
- Recursive references are marked with a *recurse symbol* (). Click this symbol to navigate between the element declaration and its reference.

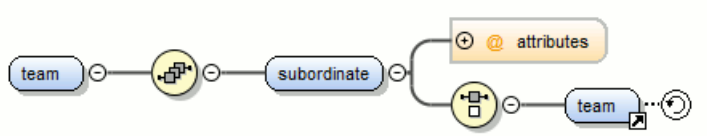

Figure 445: Recursive Reference

Schema Editing Actions

You can edit an XML schema using drag and drop operations or contextual menu actions.

Drag and drop is the easiest way to move the existing components to other locations in an XML schema. For example, you can quickly insert an element reference in the diagram with a drag and drop from the ***Outline*** *view* to a compositor in the diagram. Also, the components order in an `xs:sequence` can be easily changed using drag and drop.

If this property has not been set, you can easily set the attribute/element type by dragging over it a simple type or complex type from the diagram. If the type property for a simple type or complex type is not already set, you can set it by dragging over it a simple or complex type.

Depending on the drop area, various actions are available:

- **move** - Context dependent, the selected component is moved to the destination.
- **reference** - Context dependent, the selected component is referenced from the parent.
- **copy** - If **(Ctrl (Meta on Mac OS))** key is pressed, a copy of the selected component is inserted to the destination.

Visual clues about the operation type are indicated by the mouse pointer shape:

- - When moving a component.
- - When referencing a component.
- - When copying a component.

You can edit some schema components directly in the diagram. For these components, you can edit the name and the additional properties presented in the diagram by double clicking the value you want to edit. If you want

to edit the name of a selected component, you can also press **(Enter)**. The list of properties that can be displayed for each component can be customized *in the Preferences*.

When editing references, you can choose from a list of available components. Components from an imported schema for which the target namespace does not have an associated prefix is displayed in the list as `componentName#targetNamespace`. If the reference is from a target namespace that was not yet mapped, you are prompted to add prefix mappings for the inserted component namespace in the current edited schema.

You can also change the compositor by double-clicking it and choose the compositor you want from the proposals list.

There are some components that cannot be edited directly in the diagram: imports, includes, redefines. The editing action can be performed if you double-click or press **(Enter)** on an import/include/redefine component. An edit dialog box is displayed, allowing you to customize the directives.

Searching and Refactoring Actions in XML Schemas

XML Schema Component Dependencies View

XML Schema Resource Hierarchy / Dependencies View

Generating Sample XML Files

Schema Design Preferences on page 93

Contextual Menu Actions in the Design Mode

The contextual menu of the **Design** mode includes the following actions:

Go to Definition (Ctrl + Shift + Enter)

Shows the definition for the current selected component. For references, this action is available by clicking the arrow displayed in its bottom right corner.

Open Schema (Ctrl + Shift + Enter)

Opens the selected schema. This action is available for `xsd:import`, `xsd:include` and `xsd:redefine` elements. If the file you try to open does not exist, a warning message is displayed and you have the possibility to create the file.

Edit Attributes ()

Allows you to edit the attributes of the selected component in a small in-place editor that presents the same attributes as in the ***Attributes*** *view* and the ***Facets*** *view*. The actions that can be performed on attributes in this dialog box are the same actions presented in the two views.

Append child

Offers a list of valid components, depending on the context, and appends your selection as a child of the currently selected component. You can set a name for a named component after it has been added in the diagram.

Insert before

Offers a list of valid components, depending on the context, and inserts your selection before the selected component, as a sibling. You can set a name for a named component after it has been added in the diagram.

Insert after

Offers a list of valid components, depending on the context, and inserts your selection after the selected component, as a sibling. You can set a name for a named component after it has been added in the diagram.

New global

Inserts a global component in the schema diagram. This action does not depend on the current context. If you choose to insert an import you have to specify the URL of the imported file, the target namespace and the import ID. The same information, excluding the target namespace, is requested for an `xsd:include` or `xsd:redefine` element.

Note: If the imported file has declared a target namespace, the field **Namespace** is completed automatically.

Edit Schema Namespaces

When performed on the schema root, it allows you to edit the schema target namespace and namespace mappings. You can also invoke the action by double-clicking the target namespace property from ***Attributes view*** for the schema or by double-clicking the schema component.

Edit Annotations

Allows you to edit the annotation for the selected schema component in the **Edit Annotations** dialog box. You can perform the following operations in the dialog box:

- **Edit all `appinfo/documentation` items for a specific annotation** - All `appinfo/documentation` items for a specific annotation are presented in a table and can be easily edited. Information about an annotation item includes: type (documentation/appinfo), content, source (optional, specify the source of the `documentation/appinfo` element) and `xml:lang`. The content of a `documentation/appinfo` item can be edited in the **Content** area below the table.
- **Insert/Insert before/Remove documentation/appinfo.** The **Add** button allows you to insert a new annotation item (`documentation/appinfo`). You can add a new item before the item selected in table by pressing the **Insert Before** button. Also, you can delete the selected item using the **Remove** button.
- **Move items up/down** - to do this use the **Move up** and **Move down** buttons.
- **Insert/Insert before/Remove annotation** - Available for components that allow multiple annotations such as schemas or redefines.
- **Specify an ID for the component annotation**. An optional identifier for the annotation.

Annotations are rendered by default under the graphical representation of the component. When you have a reference to a component with annotations, these annotations are presented in the diagram also below the reference component. The **Edit Annotations** action invoked from the contextual menu edit the annotations for the reference. If the reference component does not have annotations, you can edit the annotations of the referenced component by double-clicking the annotations area. Otherwise, you can edit the referenced component annotations only if you go to the definition of the component.

Note: For imported/included components that do not belong to the currently edited schema, the **Edit Annotations** dialog box presents the annotation as read-only. To edit its annotation, open the schema where the component is defined.

Extract Global Element

Action that is available for local elements. A local element is made global and is replaced with a reference to the global element. The local element properties that are also valid for the global element declaration are kept.

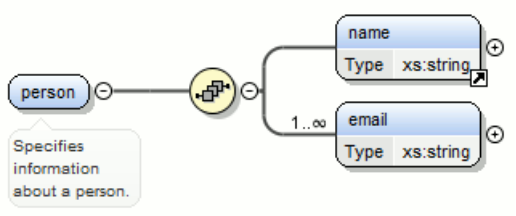

Figure 446: Extracting a Global Element

If you use the **Extract Global Element** action on a `name` element , the result is:

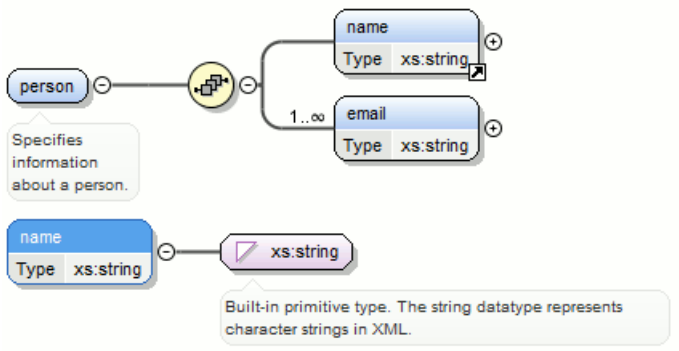

Figure 447: Extracting a Global Element on a `name` Element

Extract Global Attribute

Action available for local attributes. A local attribute is made global and replaced with a reference to the global attribute. The properties of local attribute that are also valid in the global attribute declaration are kept.

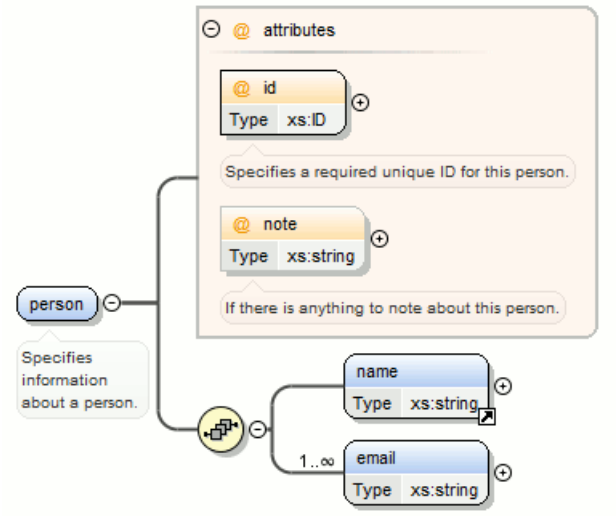

Figure 448: Extracting a Global Attribute

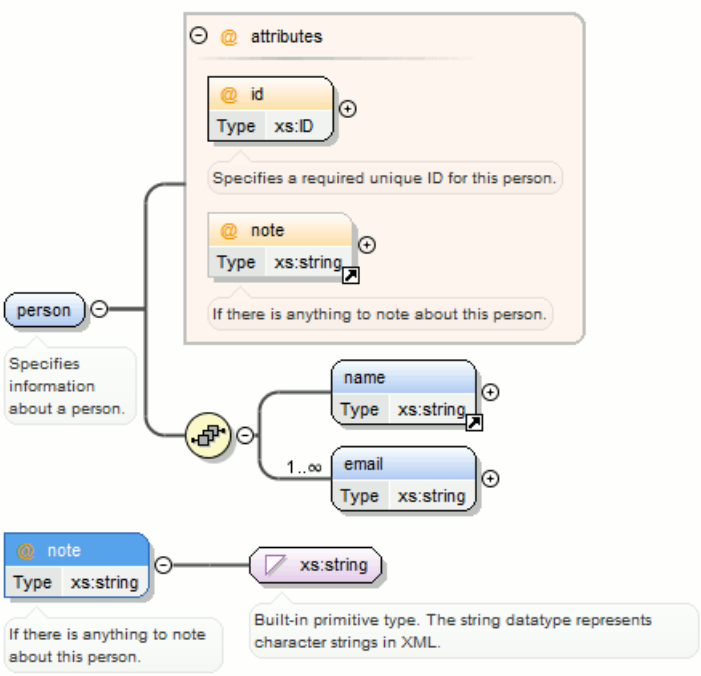
If you use the **Extract Global Attribute** action on a `note` attribute, the result is:



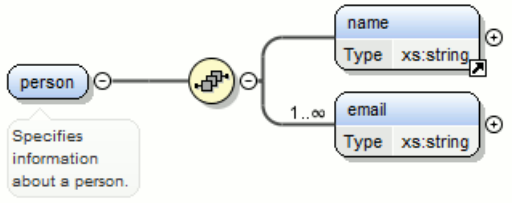


Figure 449: Extracting a Global Attribute on a `note` Attribute

Extract Global Group

Action available for compositors (sequence, choice, all). This action extracts a global group and makes a reference to it. The action is available only if the parent of the compositor is not a group.

If you use the **Extract Global Group** action on the `sequence` element, the **Extract Global Component** dialog box is displayed and you can choose a name for the group. If you type `personGroup`, the result is:

Figure 450: Extracting a Global Group

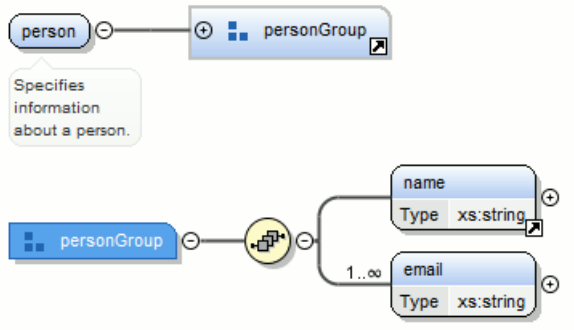

Figure 451: Extracting a Global Gropu on a `sequence` Element

Extract Global Type

Action used to extract an anonymous simple type or an anonymous complex type as global. For anonymous complex types, the action is available on the parent element.

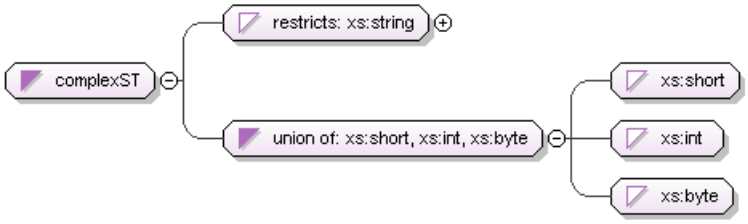

Figure 452: Extracting a Global Simple Type

If you use the action on the `union` component and choose `numericST` for the new global simple type name, the result is:

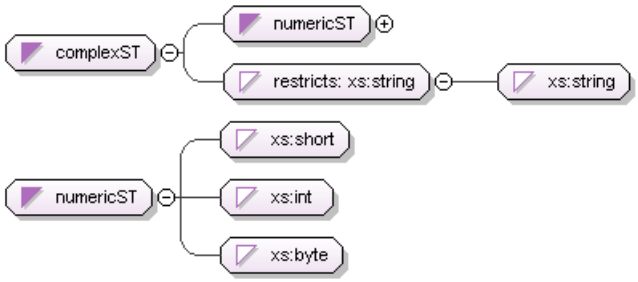

Figure 453: Extracting a Global Simple Type on a `union` Component

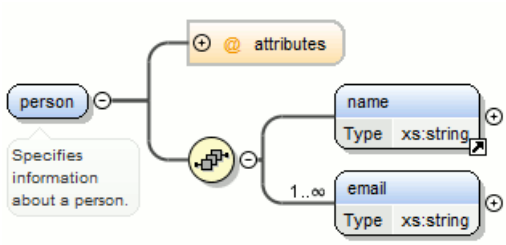

Figure 454: Extracting a Global Complex Type

If you use the action on a `person` element and choose `person_type` for the new complex type name, the result is:

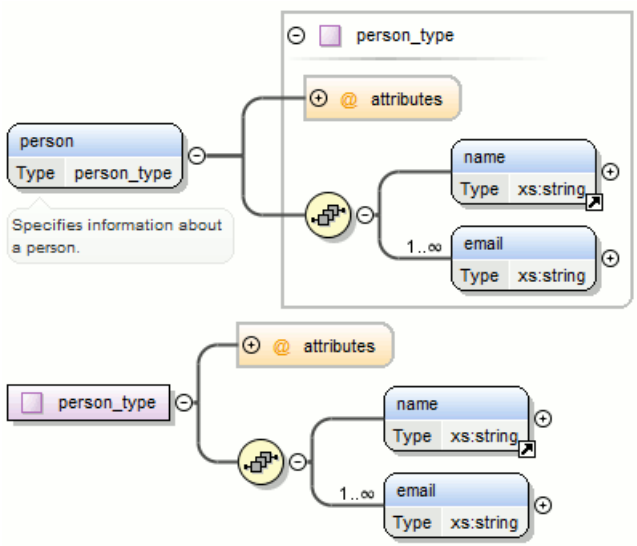

Figure 455: Extracting a Global Complex Type on a `person` Element

Rename Component in

Rename the selected component.

Cut Ctrl + X (Command + X on OS X)

Cut the selected component(s).

Copy Ctrl + C (Command + C on OS X)

Copy the selected component(s).

Copy XPath

This action copies an XPath expression that identifies the selected element or attribute in an instance XML document of the edited schema and places it in the clipboard.

Paste Ctrl + V (Command + V on OS X)

Paste the component(s) from the clipboard as children of the selected component.

Paste as Reference

Create references to the copied component(s). If not possible a warning message is displayed.

Remove (Delete)

Remove the selected component(s).

Override component

Copies the overridden component in the current XML Schema. This option is available for `xs:override` components.

Redefine component

The referenced component is added in the current XML Schema. This option is available for `xs:redefine` components.

Optional

Can be performed on element/attribute/group references, local attributes, elements, compositors, and element wildcards. The `minOccurs` property is set to 0 and the `use` property for attributes is set to `optional`.

Unbounded

Can be performed on element/attribute/group references, local attributes, elements, compositors, and element wildcards. The `maxOccurs` property is set to `unbounded` and the `use` property for attributes is set to `required`.

Search

Can be performed on local elements or attributes. This action makes a reference to a global element or attribute.

Search References

Searches all references of the item found at current cursor position in the defined scope if any.

Search References in

Searches all references of the item found at current cursor position in the specified scope.

Search Occurrences in File

Searches all occurrences of the item found at current cursor position in the current file.

Component Dependencies

Opens the ***Component Dependencies*** *view* that allows you to see the dependencies for the current selected component.

Resource Hierarchy

Opens the ***Resource Hierarchy / Dependencies*** *view* that allows you to see the hierarchy for the current selected resource.

Flatten Schema

Recursively adds the components of included Schema files to the main one. It also flattens every imported XML Schema from the hierarchy.

Resource Dependencies

Allows you to see the dependencies for the current selected resource.

Expand All

Recursively expands all sub-components of the selected component.

Collapse All

Recursively collapses all sub-components of the selected component.

Save as Image

Save the diagram as image, in JPEG, BMP, SVG or PNG format.

Generate Sample XML Files

Generate XML files using the current opened schema. The selected component is the XML document root. See more in the *Generate Sample XML Files* section.

Options

Show the *Schema preferences panel*.

XML Schema Components

A schema diagram contains a series of interconnected components. To quickly identify the relation between two connected components, the connection is represented as:

- A thick line to identify a connection with a required component (in the following image, `family` is a required element).

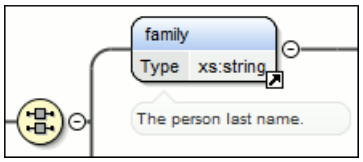

Figure 456: Example: Required Component

- A thin line to identify a connection with an optional component (in the following image, `email` is an optional element).

Figure 457: Example: Optional Component

The following topics explain in detail all available components and their symbols as they appear in an XML schema diagram.

xs:schema

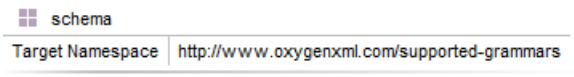

Figure 458: The *xs:schema* Component

Defines the root element of a schema. A schema document contains representations for a collection of schema components, such as type definitions and element declarations, that have a common target namespace. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-schema*.

By default, it displays the *targetNamespace* property when rendered.

Table 42: *xs:schema* Properties

Property Name	Description	Possible Values
Target Namespace	The schema target namespace.	Any URI
Element Form Default	Determining whether or not local element declarations will be namespace-qualified by default.	qualified, unqualified, [Empty]. Default value is unqualified.
Attribute Form Default	Determining whether or not local attribute declarations will be namespace-qualified by default.	qualified, unqualified, [Empty]. Default value is unqualified.
Block Default	Default value of the *block* attribute of *xs:element* and *xs:complexType*.	#all, extension, restriction, substitution, restriction extension, restriction substitution, extension substitution, restriction extension substitution, [Empty].
Final Default	Default value of the *final* attribute of *xs:element* and *xs:complexType*.	#all, restriction, extension, restriction extension, [Empty].
Default Attributes	Specifies a set of attributes that apply to every complex Type in a schema document.	Any.
Xpath Default Namespace	The default namespace used when the XPath expression is evaluated.	##defaultNamespace, ##targetNamespace, ##local.
Version	Schema version	Any token.
ID	The schema ID	Any ID.
Component	The edited component name.	Not editable property.
SystemID	The schema system ID	Not editable property.

xs:element

Figure 459: The *xs:element* Component

Defines an element. An element declaration is an association of a name with a type definition, either simple or complex, an (optional) default value and a (possibly empty) set of identity-constraint definitions. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-element*.

An element by default displays the following properties when rendered in the diagram: *default*, *fixed*, *abstract* and *type*. When referenced or declared locally, the element graphical representation also contains the value for the *minOccurs* and *maxOccurs* properties (for 0..1 and 1..1 occurs the values are implied by the connector style) and the connectors to the element are drawn using dotted lines if the element is optional.

Table 43: *xs:element* Properties

Property Name	Description	Possible Values	Mentions
Name	The element name. Always required.	Any NCName for global or local elements, any *QName* for element references.	If missing, will be displayed as '[element]' in diagram.
Is Reference	When set, the local element is a reference to a global element.	true/false	Appears only for local elements.
Type	The element type.	All declared or built-in types. In addition, the following anonymous types are available: [ST-restriction], [ST-union], [ST-list], [CT-anonymous], [CT-extension SC], [CT-restriction SC], [CT-restriction CC], [CT-extension CC].	For all elements. For references, the value is set in the referenced element.
Base Type	The extended/restricted base type.	All declared or built-in types	For elements with complex type, with simple or complex content.
Mixed	Defines if the complex type content model will be mixed.	true/false	For elements with complex type.
Content	The content of the complex type.	simple/complex	For elements with complex type that extends/restricts a base type. It is automatically detected.
Content Mixed	Defines if the complex content model will be mixed.	true/false	For elements with complex type that has a complex content.
Default	Default value of the element. A default value is automatically assigned to the element when no other value is specified.	Any string	The fixed and default attributes are mutually exclusive.
Fixed	A simple content element may be fixed to a specific value using this attribute. A fixed value is also automatically assigned to the element and you cannot specify another value.	Any string	The fixed and default attributes are mutually exclusive.

Property Name	Description	Possible Values	Mentions
Min Occurs	Minimum number of occurrences of the element.	A numeric positive value. Default value is 1	Only for references/local elements
Max Occurs	Maximum number of occurrences of the element.	A numeric positive value. Default value is 1	Only for references/local elements
Substitution Group	Qualified name of the head of the substitution group that this element belongs to.	All declared elements. For XML Schema 1.1 this property supports multiple values.	For global and reference elements
Abstract	Controls whether or not the element may be used directly in instance XML documents. When set to true, the element may still be used to define content models, but it must be substituted through a substitution group in the instance document.	true/false	For global elements and element references
Form	Defines if the element is "qualified" (belongs to the target namespace) or "unqualified" (doesn't belong to any namespace).	unqualified/qualified	Only for local elements
Nillable	When this attribute is set to true, the element can be declared as nil using an *xsi:nil* attribute in the instance documents.	true/false	For global elements and element references
Target Namespace	Specifies the target namespace for local element and attribute declarations. The namespace URI may be different from the schema target namespace. This property is available for local elements only.	Not editable property.	For all elements.

Property Name	Description	Possible Values	Mentions
Block	Controls if the element can be subject to a type or substitution group substitution. '#all' blocks any substitution, 'substitution' blocks any substitution through substitution groups and 'extension'/'restriction' block any substitution (both through *xsi:type* and substitution groups) by elements or types, derived respectively by extension or restriction from the type of the element. Its default value is defined by the *blockDefault* attribute of the parent *xs:schema*.	#all, restriction, extension,substitution, extension restriction, extension substitution, restriction substitution, restriction extension substitution	For global elements and element references
Final	Controls whether the element can be used as the head of a substitution group for elements whose types are derived by extension or restriction from the type of the element. Its default value is defined by the *finalDefault* attribute of the parent *xs:schema*.	#all, restriction, extension, restriction extension, [Empty]	For global elements and element references
ID	The component ID.	Any ID	For all elements.
Component	The edited component name.	Not editable property.	For all elements.
Namespace	The component namespace.	Not editable property.	For all elements.
System ID	The component system ID.	Not editable property.	For all elements.

xs:attribute

Figure 460: The *xs:attribute* Component

Defines an attribute. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-attribute*.

An attribute by default displays the following properties when rendered in the diagram: *default*, *fixed*, *use* and *type*. Connectors to the attribute are drawn using dotted lines if the attribute use is optional. The attribute name is stroked out if prohibited.

Table 44: *xs:attribute* Properties

Property Name	Description	Possible Value	Mentions
Name	Attribute name. Always required.	Any NCName for global/ local attributes, all declared attributes' *QName* for references.	For all local or global attributes. If missing, will be displayed as '[attribute]' in the diagram.
Is Reference	When set, the local attribute is a reference.	true/false	For local attributes.
Type	Qualified name of a simple type.	All global simple types and built-in simple types. In addition another 3 proposals are present: [anonymous restriction], [anonymous list], [anonymous union] for creating anonymous simple types more easily.	For all attributes. For references, the type is set to the referenced attribute.
Default	Default value. When specified, an attribute is added by the schema processor (if it is missing from the instance XML document) and it is given this value. The default and fixed attributes are mutually exclusive.	Any string	For all local or global attributes. For references the value is from the referenced attribute.
Fixed	When specified, the value of the attribute is fixed and must be equal to this value. The default and fixed attributes are mutually exclusive.	Any string	For all local or global attributes. For references the value is from the referenced attribute.
Use	Possible usage of the attribute. Marking an attribute "prohibited" is useful to exclude attributes during derivations by restriction.	optional, required, prohibited	For local attributes
Form	Specifies whether or not the attribute is qualified (must have a namespace prefix in the instance XML document). The default value for this attribute is specified by the *attributeFormDefault* attribute of the *xs:schema* document element.	unqualified/qualified	For local attributes.

Property Name	Description	Possible Value	Mentions
Inheritable	Specifies if the attribute is inheritable. Inheritable attributes can be used by <alternative> element on descendant elements.	true/false	For all local or global attributes. The default value is false. This property is available for XML Schema 1.1.
Target Namespace	Specifies the target namespace for local attribute declarations. The namespace URI may be different from the schema target namespace.	Any URI	Setting a target namespace for local attribute is useful only when restricts attributes of a complex type that is declared in other schema with a different target namespace. This property is available for XML Schema 1.1.
ID	The component ID.	Any ID	For all attributes.
Component	The edited component name.	Not editable property.	For all attributes.
Namespace	The component namespace.	Not editable property.	For all attributes.
System ID	The component system ID.	Not editable property.	For all attributes.

xs:attributeGroup

Figure 461: The *xs:attributeGroup* Component

Defines an attribute group to be used in complex type definitions. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-attributeGroup*.

Table 45: *xs:attributeGroup* Properties

Property Name	Description	Possible Values	Mentions
Name	Attribute group name. Always required.	Any NCName for global attribute groups, all declared attribute groups for reference.	For all global or referenced attribute groups. If missing, will be displayed as '[attributeGroup]' in diagram.
ID	The component ID.	Any ID	For all attribute groups.
Component	The edited component name.	Not editable property.	For all attribute groups.
Namespace	The component namespace.	Not editable property.	For all attribute groups.
System ID	The component system ID.	Not editable property.	For all attribute groups.

xs:complexType

Figure 462: The *xs:complexType* Component

Defines a top level complex type. Complex Type Definitions provide for: See more data at *http://www.w3.org/TR/xmlschema11-1/#element-complexType*.

- Constraining element information items by providing Attribute Declarations governing the appearance and content of attributes.
- Constraining element information item children to be empty, or to conform to a specified element-only or mixed content model, or else constraining the character information item children to conform to a specified simple type definition.
- Using the mechanisms of Type Definition Hierarchy to derive a complex type from another simple or complex type.
- Specifying post-schema-validation infoset contributions for elements.
- Limiting the ability to derive additional types from a given complex type.
- Controlling the permission to substitute, in an instance, elements of a derived type for elements declared in a content model to be of a given complex type.

Tip: A complex type that is a base type to another type will be rendered with yellow background.

Table 46: *xs:complexType* Properties

Property Name	Description	Possible Values	Mentions
Name	The name of the complex type. Always required.	Any NCName	Only for global complex types. If missing, will be displayed as '[complexType]' in diagram.
Base Type Definition	The name of the extended/restricted types.	Any from the declared simple or complex types.	For complex types with simple or complex content.
Derivation Method	The derivation method.	restriction/ extension	Only when base type is set. If the base type is a simple type, the derivation method is always extension.
Content	The content of the complex type.	simple/ complex	For complex types that extend/restrict a base type. It is automatically detected.
Content Mixed	Specifies if the complex content model will be mixed.	true/false	For complex contents.
Mixed	Specifies if the complex type content model will be mixed.	true/false	For global and anonymous complex types.

Property Name	Description	Possible Values	Mentions
Abstract	When set to *true*, this complex type cannot be used directly in the instance documents and needs to be substituted using an *xsi:type* attribute.	true/false	For global and anonymous complex types.
Block	Controls if a substitution (either through a *xsi:type* or substitution groups) can be performed for a complex type, which is an extension or a restriction of the current complex type. This attribute can only block such substitutions (it cannot "unblock" them), which can also be blocked in the element definition. The default value is defined by the *blockDefault* attribute of *xs:schema*.	all, extension, restriction, extension restriction, [Empty]	For global complex types.
Final	Controls whether the complex type can be further derived by extension or restriction to create new complex types.	all, extension, restriction, extension restriction, [Empty]	For global complex types.
Default Attributes Apply	The *schema* element can carry a *defaultAttributes* attribute, which identifies an attribute group. Each *complexType* defined in the schema document then automatically includes that attribute group, unless this is overridden by the *defaultAttributesApply* attribute on the *complexType* element.	true/false	This property is available only for XML Schema 1.1.
ID	The component ID.	Any ID	For all complex types.
Component	The edited component name.	Not editable property.	For all complex types.
Namespace	The component namespace.	Not editable property.	For all complex types.
System ID	The component system ID.	Not editable property.	For all complex types.

xs:simpleType

Figure 463: The *xs:simpleType* Component

Defines a simple type. A simple type definition is a set of constraints on strings and information about the values they encode, applicable to the normalized value of an attribute information item or of an element information item with no element children. Informally, it applies to the values of attributes and the text-only content of elements. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-simpleType*.

Tip: A simple type that is a base type to another type will be rendered with yellow background.

Table 47: *xs:simpleType* Properties

Name	Description	Possible Values	Scope
Name	Simple type name. Always required.	Any NCName.	Only for global simple types. If missing, will be displayed as '[simpleType]' in diagram.
Derivation	The simple type category: restriction, list or union.	restriction,list or union	For all simple types.
Base Type	A simple type definition component. Required if derivation method is set to restriction.	All global simple types and built-in simple types. In addition another 3 proposals are present: [anonymous restriction], [anonymous list], [anonymous union] for easily create anonymous simple types.	For global and anonymous simple types with the derivation method set to restriction.
Item Type	A simple type definition component. Required if derivation method is set to list.	All global simple types and built-in simple types(from schema for schema). In addition another 3 proposals are present: [anonymous restriction], [anonymous list], [anonymous union] for easily create anonymous simple types.	For global and anonymous simple types with the derivation method set to list. Derivation by list is the process of transforming a simple datatype (named the item type) into a whitespace-separated list of values from this datatype. The item type can be defined inline by adding a simpleType definition as a child element of the list element, or by reference, using the itemType attribute (it is an error to use both).
Member Types	Category for grouping union members.	Not editable property.	For global and anonymous simple types with the derivation method set to union.

Name	Description	Possible Values	Scope
Member	A simple type definition component. Required if derivation method is set to union.	All global simple types and built-in simple types(from schema for schema). In addition another 3 proposals are present: [anonymous restriction], [anonymous list], [anonymous union] for easily create anonymous simple types.	For global and anonymous simple types with the derivation method set to union. Deriving a simple datatype by union merges the lexical spaces of several simple datatypes (called member types) to create a new simple datatype. The member types can be defined either by reference (through the memberTypes attribute) or embedded as simple datatype local definitions in the xs:union element. Both styles can be mixed.
Final	Blocks any further derivations of this datatype (by list, union, derivation or all).	#all, list, restriction, union, list restriction, list union, restriction union. In addition, [Empty] proposal is present for set empty string as value.	Only for global simple types.
ID	The component ID.	Any ID.	For all simple types
Component	The name of the edited component.	Not editable property.	Only for global and local simple types
Namespace	The component namespace.	Not editable property.	For global simple types.
System ID	The component system ID.	Not editable property.	Not present for built-in simple types..

xs:alternative

The *type alternatives* mechanism allows you to specify type substitutions on an element declaration.

Note: *xs:alternative* is available for XML Schema 1.1.

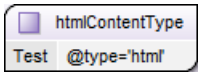

Figure 464: The *xs:alternative* Component

Table 48: *xs:alternative* Properties

Name	Description	Possible Values
Type	Specifies type substitutions for an element, depending on the value of the attributes.	All declared or built-in types. In addition, the following anonymous types are available: [ST-restriction], [ST-union], [ST-list], [CT-anonymous], [CT-extension SC], [CT-restriction SC], [CT-restriction CC], [CT-extension CC].
Test	Specifies an XPath expression. If the XPath condition is valid, the specified type is selected as the element type. The expressions allowed are limited to a subset of XPath 2.0. Only the attributes of the current element and inheritable attributes from ancestor elements are accessible in the XPath expression. When you edit this property, the content completion list of proposals offers XPath expressions.	An XPath expression.
XPath Default Namespace	The default namespace used when the XPath expression is evaluated.	##defaultNamespace, ##targetNamespace, ##local.
ID	Specifies the component ID.	Any ID.
Component	Specifies the type of XML schema component.	Not editable property.
System ID	Points to the document location of the schema.	Not editable property.

xs:group

Figure 465: The *xs:group* Component

Defines a group of elements to be used in complex type definitions. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-group*.

When referenced, the graphical representation also contains the value for the *minOccurs* and *maxOccurs* properties (for 0..1 and 1..1 occurs the values are implied by the connector style) and the connectors to the group are drawn using dotted lines if the group is optional.

Table 49: *xs:group* Properties

Property Name	Description	Possible Values	Mentions
Name	The group name. Always required.	Any NCName for global groups, all declared groups for reference.	If missing, will be displayed as '[group]' in diagram.
Min Occurs	Minimum number of occurrences of the group.	A numeric positive value. Default value is 1.	Appears only for reference groups.

Property Name	Description	Possible Values	Mentions
Max Occurs	Maximum number of occurrences of the group.	A numeric positive value. Default value is 1.	Appears only for reference groups.
ID	The component ID.	Any ID	For all groups.
Component	The edited component name.	Not editable property.	For all groups.
Namespace	The component namespace.	Not editable property	For all groups.
System ID	The component system ID.	Not editable property.	For all groups.

xs:include

Figure 466: The *xs:include* Component

Adds multiple schemas with the same target namespace to a document. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-include*.

Table 50: *xs:include* properties

Property Name	Description	Possible Values
Schema Location	Included schema location.	Any URI
ID	Include ID.	Any ID
Component	The component name.	Not editable property.

xs:import

Figure 467: The *xs:import* Component

Adds multiple schemas with a different target namespace to a document. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-import*.

Table 51: *xs:import* Properties

Property Name	Description	Possible Values
Schema Location	Imported schema location	Any URI
Namespace	Imported schema namespace	Any URI
ID	Import ID	Any ID
Component	The component name	Not editable property.

xs:redefine

Figure 468: The *xs:redefine* Component

Redefines simple and complex types, groups, and attribute groups from an external schema. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-redefine*.

Table 52: *xs:redefine* Properties

Property Name	Description	Possible Values
Schema Location	Redefine schema location.	Any URI
ID	Redefine ID	Any ID
Component	The component name.	Not editable property.

xs:override

Figure 469: The *xs:override* Component

The override construct allows replacements of old components with new ones without any constraint. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-override*.

Table 53: *xs:override* Properties

Property Name	Description	Possible Values
Schema Location	Redefine schema location.	Any URI
ID	Redefine ID	Any ID

xs:notation

Figure 470: The *xs:notation* Component

Describes the format of non-XML data within an XML document. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-notation*.

Table 54: *xs:notation* Properties

Property Name	Description	Possible values	Mentions
Name	The notation name. Always required.	Any NCName.	If missing, will be displayed as '[notation]' in diagram.
System Identifier	The notation system identifier.	Any URI	Required if public identifier is absent (otherwise, optional).
Public Identifier	The notation public identifier.	A Public ID value	Required if system identifier is absent (otherwise, optional).
ID	The component ID.	Any ID	For all notations.
Component	The edited component name.	Not editable property.	For all notations.
Namespace	The component namespace.	Not editable property.	For all notations.

Property Name	Description	Possible values	Mentions
System ID	The component system ID.	Not editable property.	For all notations.

xs:sequence / xs:choice / xs:all

Figure 471: *xs:sequence*

xs:sequence specifies that the child elements must appear in a sequence. Each child element can occur from 0 to any number of times. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-sequence*.

Figure 472: *xs:choice*

xs:choice allows only one of the elements contained in the declaration to be present within the containing element. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-choice*.

Figure 473: *xs:all*

xs:all specifies that the child elements can appear in any order. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-all*.

The compositor graphical representation also contains the value for the *minOccurs* and *maxOccurs* properties (for 0..1 and 1..1 occurs the values are implied by the connector style) and the connectors to the compositor are drawn using dotted lines if the compositor is optional.

Table 55: *xs:sequence*, *xs:choice*, *xs:all* Properties

Property Name	Description	Possible Values	Mentions
Compositor	Compositor type.	sequence, choice, all.	'all' is only available as a child of a group or complex type.
Min Occurs	Minimum occurrences of compositor.	A numeric positive value. Default is 1.	The property is not present if compositor is 'all' and is child of a group.
Max Occurs	Maximum occurrences of compositor.	A numeric positive value. Default is 1.	The property is not present if compositor is 'all' and is child of a group.
ID	The component ID.	Any ID	For all compositors.
Component	The edited component name.	Not editable property.	For all compositors.
System ID	The component system ID.	Not editable property.	For all compositors.

xs:any

Figure 474: The *xs:any* Component

Enables the author to extend the XML document with elements not specified by the schema. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-any*.

The graphical representation also contains the value for the *minOccurs* and *maxOccurs* properties (for 0..1 and 1..1 occurs the values are implied by the connector style) and the connectors to the wildcard are drawn using dotted lines if the wildcard is optional.

Table 56: *xs:any* Properties

Property Name	Description	Possible Values
Namespace	The list of allowed namespaces. The namespace attribute expects a list of namespace URIs. In this list, two values have a specific meaning: '##targetNamespace' stands for the target namespace, and '##local' stands for local attributes (without namespaces).	##any, ##other, ##targetNamespace, ##local or anyURI
notNamespace	Specifies the namespace that extension elements or attributes cannot come from.	##local, ##targetNamespace
notQName	Specifies an element or attribute that is not allowed.	##defined
Process Contents	Type of validation required on the elements allowed for this wildcard.	skip, lax, strict
Min Occurs	Minimum occurrences of any	A numeric positive value. Default is 1.
Max Occurs	Maximum occurrences of any	A numeric positive value. Default is 1.
ID	The component ID.	Any ID.
Component	The name of the edited component.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:anyAttribute

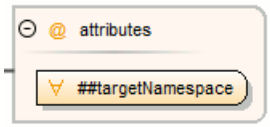

Figure 475: The *xs:anyAttribute* Component

Enables the author to extend the XML document with attributes not specified by the schema. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-anyAttribute*.

Table 57: *xs:anyAttribute* Properties

Property Name	Description	Possible Value
Namespace	The list of allowed namespaces. The namespace attribute expects a list of namespace URIs. In this list, two values have a specific meaning: '##targetNamespace' stands for the target namespace, and '##local' stands for local attributes (without namespaces).	##any, ##other, ##targetNamespace, ##local or anyURI
Process Contents	Type of validation required on the elements allowed for this wildcard.	skip, lax, strict
ID	The component ID.	Any ID.
Component	The name of the edited component.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:unique

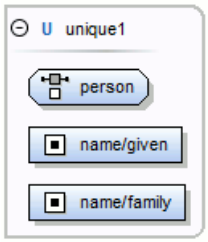

Figure 476: The *xs:unique* Component

Defines that an element or an attribute value must be unique within the scope. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-unique*.

Table 58: *xs:unique* Properties

Property Name	Description	Possible Values
Name	The unique name. Always required.	Any NCName.
ID	The component ID.	Any ID.
Component	The edited component name.	Not editable property.
Namespace	The component namespace.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:key

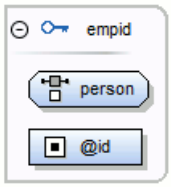

Figure 477: The *xs:key* Component

Specifies an attribute or element value as a key (unique, non-nullable and always present) within the containing element in an instance document. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-key*.

Table 59: *xs:key* Properties

Property Name	Description	Possible Value
Name	The key name. Always required.	Any NCName.
ID	The component ID.	Any ID.
Component	The edited component name.	Not editable property.
Namespace	The component namespace.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:keyRef

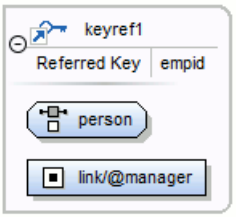

Figure 478: The *xs:keyRef* Component

Specifies that an attribute or element value corresponds to that of the specified key or unique element. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-keyref*.

A keyref by default displays the *Referenced Key* property when rendered.

Table 60: *xs:keyRef* Properties

Property Name	Description	Possible Values
Name	The keyref name. Always required.	Any NCName.
Referenced Key	The name of referenced key.	any declared element constraints.
ID	The component ID.	Any ID.
Component	The edited component name.	Not editable property.
Namespace	The component namespace.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:selector

Figure 479: The *xs:selector* Component

Specifies an XPath expression that selects a set of elements for an identity constraint. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-selector*.

Table 61: *xs:selector* Properties

Property Name	Description	Possible Values
XPath	Relative XPath expression identifying the element that the constraint applies to.	An XPath expression.
ID	The component ID.	Any ID.
Component	The edited component name.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:field

Figure 480: The *xs:field* Component

Specifies an XPath expression that specifies the value used to define an identity constraint. See more info at *http://www.w3.org/TR/xmlschema11-1/#element-field*.

Table 62: *xs:field* Properties

Property Name	Description	Possible Values
XPath	Relative XPath expression identifying the field(s) composing the key, key reference, or unique constraint.	An XPath expression.
ID	The component ID.	Any ID.
Component	The edited component name.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:assert

Assertions provide a flexible way to control the occurrence and values of elements and attributes available in an XML Schema.

Note: *xs:assert* is available for XML Schema 1.1.

Figure 481: The *xs:assert* Component

Table 63: *xs:assert* Properties

Property Name	Description	Possible Values
Test	Specifies an XPath expression. If the XPath condition is valid, the specified type is selected as the element type. The expressions allowed are limited to a subset of XPath 2.0. Only the attributes of the current element and inheritable attributes from ancestor elements are accessible in the XPath expression. When you edit this property, the content completion list of proposals offers XPath expressions.	An XPath expression.
XPath Default Namespace	The default namespace used when the XPath expression is evaluated.	##defaultNamespace, ##targetNamespace, ##local.
ID	Specifies the component ID.	Any ID.
Component	The edited component name.	Not editable property.
System ID	The component system ID.	Not editable property.

xs:openContent

Figure 482: The *xs:openContent* Component

The *openContent* element enables instance documents to contain extension elements to be inserted amongst the elements declared by the schema. You can declare open content for your elements at one place (within the *complexType* definition) or at the schema level.

For further details about the *openContent* component, go to *http://www.w3.org/TR/xmlschema11-1/#element-openContent*.

Table 64: *xs:openContent* Properties

Property Name	Description	Possible Value
Mode	Specifies where the extension elements can be inserted.	The value can be: "interleave", "suffix" or "none". The default value is "interleave".
ID	The component ID.	Any ID.
Component	The edited component name.	Not editable property.
System ID	The component system ID.	Not editable property.

Note: This component is available for XML Schema 1.1 only. To change the version of the XML Schema, *open the **Preferences** dialog box **(Options > Preferences)*** and go to **XML** > **XML Parser** > **XML Schema**.

Constructs Used to Group Schema Components

This section explains the components that can be used for grouping other schema components:

- *Attributes*

- *Constraints*
- *Substitutions*

Attributes

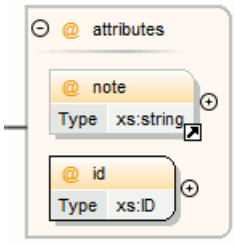

Figure 483: Attributes Construct

Groups all attributes and attribute groups belonging to a complex type.

Table 65: *attributes* Properties

Property Name	Description	Possible Values
Component	The element for which the attributes are displayed.	Not editable property.
System ID	The component system ID.	Not editable property.

Constraints

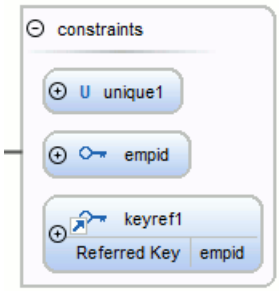

Figure 484: Constraints Construct

Groups all constraints (*xs:key*, *xs:keyRef* or *xs:unique*) belonging to an element.

Table 66: *constraints* Properties

Property Name	Description	Possible Values
Component	The element for which the constraints are displayed.	Not editable property.
System ID	The component system ID.	Not editable property.

Substitutions

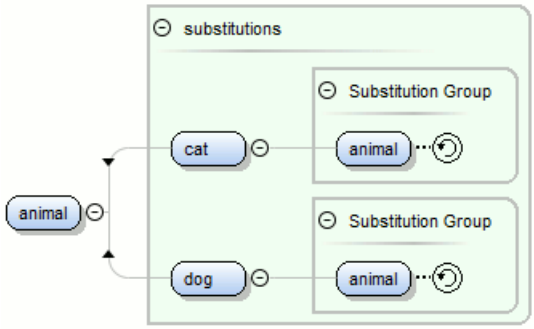

Figure 485: Substitutions Construct

Groups all elements that can substitute the current element.

Table 67: *substitutions* Properties

Property Name	Description	Possible Values
Component	The element for which the substitutions are displayed.	Not editable property.
System ID	The component system ID.	Not editable property.

Schema Validation

Validation for the **Design** mode is seamlessly integrated in the Oxygen XML Editor *XML documents validation* capability.

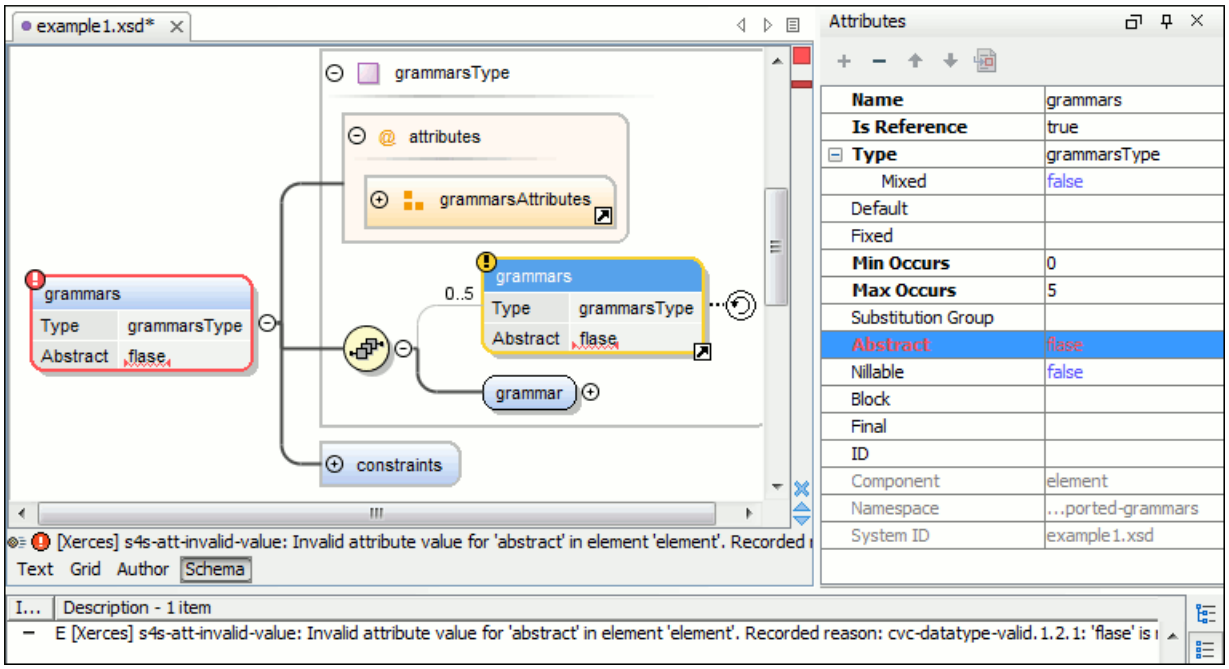

Figure 486: XML Schema Validation

A schema validation error is presented by highlighting the invalid component:

- In the *Attributes View*.
- In the diagram by surrounding the component that has the error with a red border.
- A marker on the errors stripe at the right of the diagram view.
- A status label with a red icon (!) below the diagram view.

Invalid facets for a component are highlighted in the *Facets View*.

Components with invalid properties are rendered with a red border. This is a default color, but you can customize it in the *Document checking user preferences*. When hovering an invalid component, the tooltip will present the validation errors associated with that component.

When editing a value that is supposed to be a qualified or unqualified XML name, the application provides automatic validation of the entered value. This proves to be very useful in avoiding setting invalid XML names for the given property.

If you validate the entire schema using the **Validate** action from the **Document** > **Validate** menu or from the **Validation** toolbar drop-down menu, all validation errors will be presented in the **Errors** tab. To resolve an error, just click it (or double-click for errors located in other schemas) and the corresponding schema component will be displayed as the diagram root so that you can easily correct the error.

Important: If the schema imports only the namespace of other schema without specifying the schema location and a *catalog is set-up* that maps the namespace to a certain location both the validation and the diagram will correctly identify the imported schema.

Tip: If the validation action finds that the schema contains unresolved references, the application will suggest the use of validation scenarios, but only if the current edited schema is an XML Schema module.

Edit Schema Namespaces

You can use the **XML Schema Namespaces** dialog box to easily set a target namespace and define namespace mappings for a newly created XML Schema. In the **Design** mode these namespaces can be modified anytime by choosing **Edit Schema Namespaces** from the contextual menu. You can also do this by double-clicking the schema root in the diagram.

The **XML Schema Namespaces** dialog box allows you to edit the following information:

- **Target namespace** - The target namespace of the schema.
- **Prefixes** - The dialog box displays a table with namespaces and the mapped prefixes. You can add a new prefix mapping or remove an already existing one.

Editing XML Schema in Text Editing Mode

The Oxygen XML Editor **Text** editing mode can be used for editing XML Schema in a source editing mode. It offers powerful content completion support, a synchronized Outline view, and multiple *refactoring actions*. The Outline view has two display modes: the *standard outline* mode and the *components* mode.

A diagram of the XML Schema can be presented side by side with the text. To activate the diagram presentation, select the *Show Full Model XML Schema diagram option* in the ***Diagram*** *preferences page*.

Editing XML Schema in the Master Files Context

Smaller interrelated modules that define a complex XML Schema cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, an element defined in a main schema document is not visible when you edit an included module. Oxygen XML Editor provides the support for defining the main module (or modules), thus allowing you to edit any of the imported/included schema files in the context of the larger schema structure.

You can set a main XML document either using the *master files support from the* ***Project*** *view*, or using a validation scenario.

To set a *master file* using a validation scenario, add validation units that point to the main schemas. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main schema. In this case, it considers the current module as the main schema.

The advantages of editing in the context of a *master file* include:

- Correct validation of a module in the context of a larger schema structure.
- *Content Completion Assistant* displays all the referable components valid in the current context. This include components defined in modules other than the currently edited one.
- The ***Outline*** *view* displays the components collected from the entire schema structure.

Validating XML Schema Documents

By default, XML Schema files are validated as you type. To change this, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Document Checking**, and deselect the ***Enable automatic validation** option*.

To validate an XML Schema document manually, select the **Validate** action from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu. When Oxygen XML Editor validates an XML Schema file, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Validation of an XML Schema containing a type definition with a `minOccurs` or `maxOccurs` attribute having a value larger than 256 limits the value to 256 and issues a warning about this restriction in the Message panel at the bottom of the Oxygen XML Editor window. Otherwise, for large values of the `minOccurs` and `maxOccurs` attributes, the validator fails with an **OutOfMemory** error that might make Oxygen XML Editor unusable without restarting the entire application.

Important: If the schema imports only a namespace without specifying the schema location and a *catalog is set up* to map the namespace to a certain location, both validation and the schema components will correctly identify the imported schema.

Quick Fixes for DTD, XSD, and Relax NG Errors

Oxygen XML Editor offers *Quick Fixes* for common errors that appear in XML documents that are validated against DTD, XSD, or Relax NG schemas.

Note: For XML documents validated against XSD schemas, the *Quick Fixes* are only available if you use the default Xerces validation engine.

Quick Fixes are available in **Text** mode and **Author** mode.

Oxygen XML Editor provides *Quick Fixes* for numerous types of problems, including the following:

Problem Type	Available Quick Fixes
A specific element is required in the current context	Insert the required element
An element is invalid in the current context	Remove the invalid element
The content of the element should be empty	Remove the element content
An element is not allowed to have child elements	Remove all child elements
Text is not allowed in the current element	Remove the text content
A required attribute is missing	Insert the required attribute
An attribute is not allowed to be set for the current element	Remove the attribute
The attribute value is invalid	Propose the correct attribute values
ID value is already defined	Generate a unique ID value
References to an invalid ID	Change the reference to an already defined ID

Related Information:

Schematron Quick Fixes (SQF) on page 674

Content Completion in XML Schema

The intelligent *Content Completion Assistant* allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.

The *Content Completion Assistant* is enabled by default. To disable it, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Content Completion**, and deselect the ***Enable content completion** option*.

When active, the *Content Completion Assistant* displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut. You can navigate through the list of proposals by using the **Up** and **Down** keys on your keyboard. For each selected item in the list, the *Content Completion Assistant* displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected content in **Text** mode, do one of the following:

- Press **Enter** or **Tab** to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.
- Press **Ctrl + Enter (Command + Enter on OS X)** to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

Depending on the *selected schema version*, Oxygen XML Editor populates the proposals list with information taken either from XML Schema 1.0 or 1.1.

Oxygen XML Editor helps you to easily reference a component by providing the list of proposals (complex types, simple types, elements, attributes, groups, attribute groups, or notations) valid in the current context. The components are collected from the current file or from the imported/included schemas.

When editing `xs:annotation/xs:appinfo` elements of an XML Schema, the *Content Completion Assistant* proposes elements and attributes from a custom schema (by default ISO Schematron). This feature can be configured from the *XSD Content Completion* preferences page.

Syntax Highlighting in XML Schema

Oxygen XML Editor supports syntax highlighting when editing XML Schema in **Text** mode to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for XML Schema files, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor** > **Syntax Highlight***.
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XSD** tab in the **Preview** pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the ***Editor** > **Syntax Highlight** > **Elements/Attributes by Prefix** preferences page*.

Related Information:

Customize Syntax Highlight colors on page 105

XML Schema Outline View

The **Outline** view for XML Schemas presents all the global components grouped by their location, namespace, or type. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

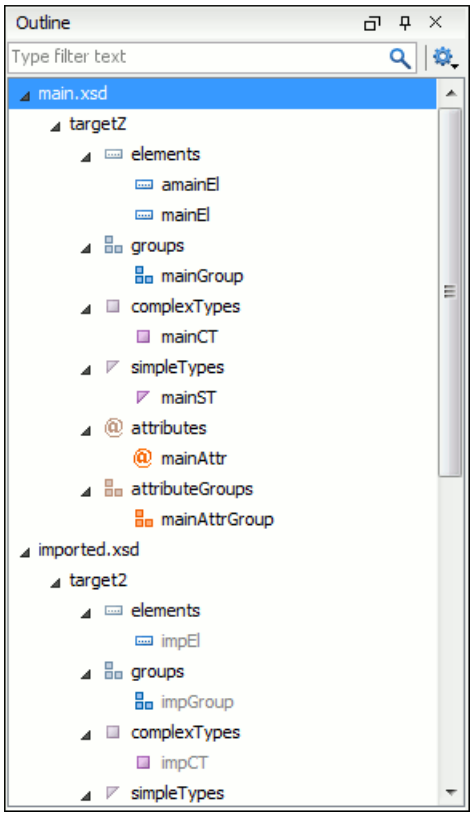

Figure 487: Outline View for XML Schema

The **Outline** view provides the following options in the **Settings** menu on the **Outline** view toolbar:

Filter returns exact matches

The text filter of the **Outline** view returns only exact matches;

Selection update on cursor move

Allows a synchronization between **Outline** view and schema diagram. The selected view from the diagram is also selected in the **Outline** view.

Sort

Allows you to sort alphabetically the schema components.

Show all components

Displays all components that were collected starting from the *master files*. Components that are not referable from the current file are marked with an orange underline. To reference them, add an import directive with the `componentNS` namespace.

Show referable components

Displays all components (collected starting from the *master files*) that can be referenced from the current file. This option is set by default.

Show only local components

Displays the components defined in the current file only.

Group by location/namespace/type

These three operations allow you to group the components by location, namespace, or type. When grouping by namespace, the main schema target namespace is the first presented in the **Outline** view.

The following contextual menu actions are available in the **Outline** view:

Remove (Delete)

Removes the selected item from the diagram.

Search References (Ctrl (Meta on Mac OS)+Shift+R)

Searches all references of the item found at current cursor position in the defined scope, if any.

Search References in

Searches all references of the item found at current cursor position in the specified scope.

Component Dependencies (Ctrl (Meta on Mac OS)+Shift+F4)

Opens the ***Component Dependencies*** *view* that allows you to see the dependencies for the current selected component.

Resource Hierarchy (F4)

Opens the ***Resource Hierarchy / Dependencies*** *view* that allows you to see the hierarchy for the current selected resource.

Resource Dependencies (Shift + F4)

Opens the ***Resource Hierarchy / Dependencies*** *view* that allows you to see the dependencies for the current selected resource.

Rename Component in

Renames the selected component.

Generate Sample XML Files

Generate XML files using the current opened schema. The selected component is the XML document root.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (*, ?) and separate multiple patterns with commas.

Tip: The search filter is case insensitive. The following wildcards are accepted:

- ***** - any string
- **?** - any character
- **,** - patterns separator

If no wildcards are specified, the string to search will be searched as a partial match.

The content of the **Outline** view and the editing area are synchronized. When you select a component in the **Outline** view, its definition is highlighted in the editing area.

Searching and Refactoring Actions in XML Schemas

XML Schema Component Dependencies View

XML Schema Resource Hierarchy / Dependencies View

Generating Sample XML Files

Editing Relax NG Schema in the Master Files Context on page 868

XML Schema Attributes View

The **Attributes** view for XML Schemas presents the properties for the selected component in the schema diagram. By default, it is displayed on the right side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

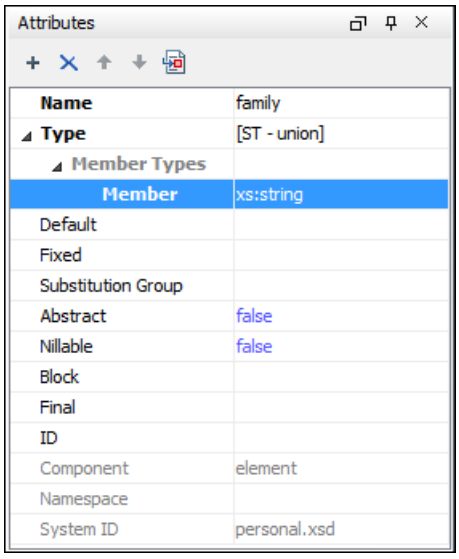

Figure 488: Attributes View

The default value of a property is presented in the **Attributes** view with blue foreground. The properties that can not be edited are rendered with gray foreground. A non-editable category that contains at least one child is rendered with bold. Bold properties are properties with values set explicitly to them.

Properties for components that do not belong to the current edited schema are read-only but if you double-click them you can choose to open the corresponding schema and edit them.

You can edit a property by double-clicking by pressing Enter. For most properties you can choose valid values from a list or you can specify another value. If a property has an invalid value or a warning, it will be highlighted in the table with the corresponding foreground color. By default, properties with errors are highlighted with red and the properties with warnings are highlighted with yellow. You can customize these colors from the *Document checking user preferences*.

For imports, includes and redefines, the properties are not edited directly in the **Attributes** view. A dialog box will open that allows you to specify properties for them.

The schema namespace mappings are not presented in **Attributes** view. You can view/edit these by choosing **Edit Schema Namespaces** from the contextual menu on the schema root. See more in the *Edit Schema Namespaces* section.

The **Attributes** view has five actions available on the toolbar and also on the contextual menu:

Add

Allows you to add a new member type to an union's member types category.

Remove

Allows you to remove the value of a property.

Move Up

Allows you to move up the current member to an union's member types category.

Move Down

Allows you to move down the current member to an union's member types category.

Copy

Copy the attribute value.

Go to Definition

Shows the definition for the selected type.

Show Facets

Allows you to edit the facets for a simple type.

XML Schema Palette View

The **Palette** view is designed to offer quick access to XML Schema components and to improve the usability of the XML Schema diagram builder. You can use the **Palette** to drag and drop components in the **Design** mode. The components offered in the **Palette** view depend on the XML schema version set in the ***XML Schema*** *preferences page*. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

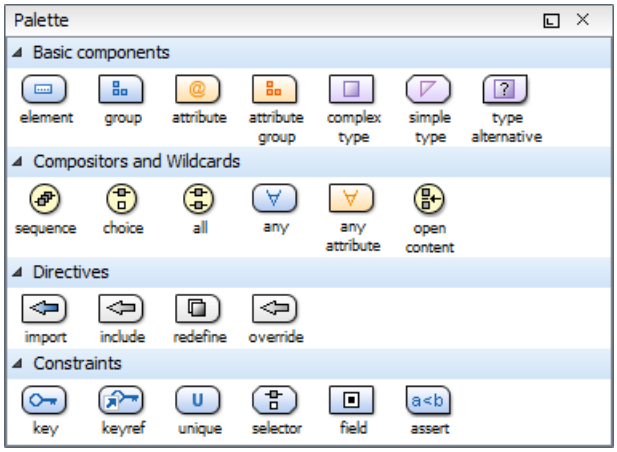

Figure 489: Palette View

Components are organized functionally into 4 collapsible categories:

- Basic components: *elements*, *group*, *attribute*, *attribute group*, *complex type*, *simple type*, *type alternative*.
- Compositors and Wildcards: *sequence*, *choice*, *all*, *any*, *any attribute*, *open content*.
- Directives: *import*, *include*, *redefine*, *override*.
- Identity constraints: *key*, *keyref*, *unique*, *selector*, *field*, *assert*.

  Note: The *type alternative*, *open content*, *override*, and *assert* components are available for XML Schema 1.1.

To add a component to the edited schema:

- Click and hold a graphic symbol from the **Palette** view, then drag the component into the **Design** view.
- A line dynamically connects the component with the XML schema structure.
- Release the component into a valid position.

  Note: You cannot drop a component into an invalid position. When you hover the component into an invalid position, the mouse cursor changes its shape into  . Also, the connector line changes its color from the usual dark gray to the color defined in the ***Validation error highlight color*** *option* (default color is red).

For more information about the Schema palette, watch our video demonstration:

XML Schema Facets View

The **Facets** view for XML Schemas presents the facets for the selected component, if available. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

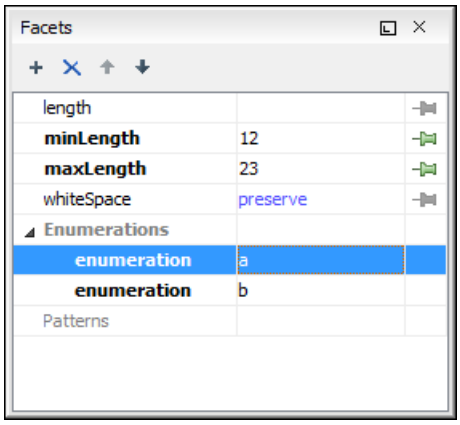

Figure 490: Facets View

The default value of a facet is rendered in the **Facets** view with a blue color. The facets that can not be edited are rendered with a gray color. The grouping categories (for example: **Enumerations** and **Patterns**) are not editable. If these categories contain at least one child they are rendered with bold. Bold facets are facets with values set explicitly to them.

Important: Usually inherited facets are presented as default in the **Facets** view but if patterns are inherited from a base type and also specified in the current simple type only the current specified patterns will be presented. You can see the effective pattern value obtained by combining the inherited and the specified patterns as a tooltip on the **Patterns** category.

Facets for components that do not belong to the current edited schema are read-only but if you double-click them you can choose to open the corresponding schema and edit them.

You can edit a facet by double-clicking it or by pressing Enter, when that facet is selected. For some facets you can choose valid values from a list or you can specify another value. If a facet has an invalid value or a warning, it will be highlighted in the table with the corresponding foreground color. By default, facets with errors are presented with red and the facets with warnings with yellow. You can customize the error colors from the *Document Checking user preferences*.

The **Facets** view provides the following actions in its toolbar and contextual menu:

Add

Allows you to add a new enumeration or a new pattern.

Remove

Allows you to remove the value of a facet.

Edit Annotations

Allows you to edit an annotation for the selected facet.

Move Up

Allows you to move up the current enumeration/pattern in **Enumerations/Patterns** category.

Move Down

Allows you to move down the current enumeration/pattern in **Enumerations/Patterns** category.

Copy

Copy the attribute value.

Open in Regular Expressions Builder

Rather than editing regular expressions manually, this action allows you to open the pattern in the *XML Schema Regular Expressions Builder* that guides you through the process of testing and constructing the pattern..

Facets can be fixed to prevent a derivation from modifying its value. To fix a facet value just press the **Pin** button.

XML Schema Resource Hierarchy / Dependencies View

The **Resource Hierarchy / Dependencies** view allows you to easily see the hierarchy / dependencies for an XML Schema, a *Relax NG schema* or an *XSLT stylesheet*. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

The **Resource Hierarchy / Dependencies** is useful when you want to start from an XML Schema (XSD) file and build and review the hierarchy of all the other XSD files that are imported, included or redefined in the given XSD file. The view is also able to build the tree structure, that is the structure of all other XSD files that import, include or redefine the given XSD file. The scope of the search is configurable (the current project, a set of local folders, etc.)

The build process for the hierarchy view is started with the **Resource Hierarchy** action available on the contextual menu of the editor panel.

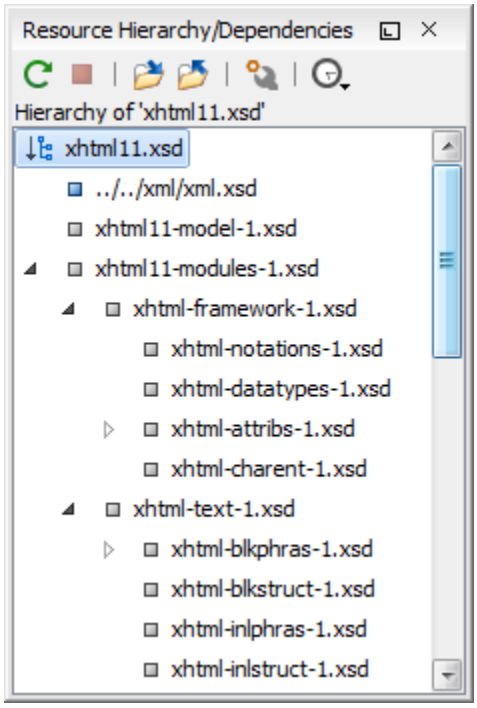

Figure 491: Resource Hierarchy/Dependencies View - Hierarchy for `xhtml11.xsd`

The build process for the dependencies view is started with the **Resource Dependencies** action available on the contextual menu.

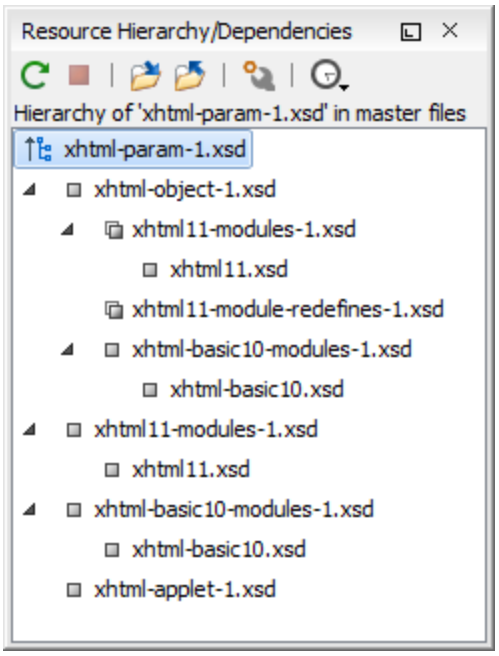

Figure 492: Resource Hierarchy/Dependencies View - Dependencies for `xhtml-param-1.xsd`

The following actions are available in the **Resource Hierarchy/Dependencies** view:

Refresh

Refreshes the Hierarchy/Dependencies structure.

Stop

Stops the hierarchy/dependencies computing.

Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

Renames the selected resource.

Show Resource Hierarchy

Shows the hierarchy for the selected resource.

Show Resource Dependencies

Shows the dependencies for the selected resource.

Add to Master Files

Adds the currently selected resource in *the **Master Files** directory*.

Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon .

Note: The **Move resource** or **Rename resource** actions give you the option to *update the references to the resource*.

Related Information:

Search and Refactor Operations Scope on page 691

Moving/Renaming XML Schema Resources

You can move and rename a resource presented in the **Resource/Hierarchy Dependencies** view, using the **Rename resource** and **Move resource** refactoring actions from the contextual menu.

When you select the **Rename** action in the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Rename resource** dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references** - Select this option to update the references to the resource you are renaming.

When you select the **Move** action from the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Move resource** dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name.

If the **Update references of the moved resource(s)** option is selected, a **Preview** option (which opens the **Preview** dialog box) is available for both actions. The **Preview** dialog box presents a list with the resources that are updated.

XML Schema Component Dependencies View

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

To see the dependencies of an XML Schema component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for all named components (for example, elements or attributes).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon .

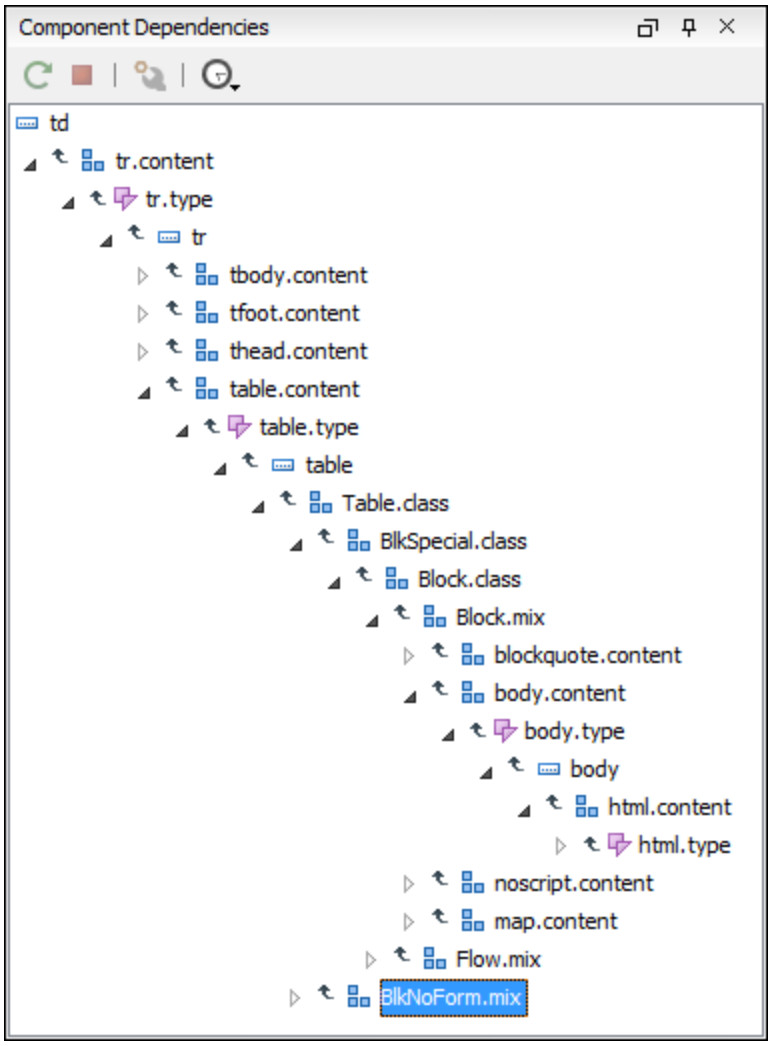

Figure 493: Component Dependencies View - Hierarchy for `xhtml11.xsd`

The **Component Dependencies** view includes the following toolbar actions:

Refresh

Refreshes the dependencies structure.

Stop

Stops the dependency computation.

Configure

Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

Go to First Reference

Selects the first reference of the currently selected component in the dependencies tree.

Go to Component

Shows the definition of the currently selected component in the dependencies tree.

For more information, see the **Maintain Complex XML Schemas** section of our **Developing XML Schemas** video demonstration:

Search and Refactor Operations Scope on page 691

Highlight Component Occurrences

When a component (for example types, elements, attributes) is found at current cursor position, Oxygen XML Editor performs a search over the entire document to find the component declaration and all its references. When found, they are highlighted both in the document and in the stripe bar, at the right side of the document. Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected and a new search is performed. All occurrences are removed when you start to edit the document.

This feature is on by default. To configured it, *open the **Preferences** dialog box **(Options > Preferences)*** and go to **Editor** > **Mark Occurrences**. A search can also be triggered with the **Search** > **Search Occurrences in File ()** contextual menu action. All matches are displayed in a separate tab of the ***Results** view*.

Searching and Refactoring Actions in XML Schemas

Search Actions

The following search actions can be applied on `attribute`, `attributeGroup`, `element`, `group`, `key`, `unique`, `keyref`, `notation`, `simple`, or `complex` types and are available from the **Search** submenu in the contextual menu of the current editor or from the **Document** > **References** menu:

- **Search References** - Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.
- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.
- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the **Document** > **Schema** menu:

- **Go to Definition** - Moves the cursor to the definition of the referenced XML Schema item.

  Note: You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

Refactoring Actions

The following refactoring actions can be applied on `attribute`, `attributeGroup`, `element`, `group`, `key`, `unique`, `keyref`, `notation`, `simple`, or `complex` types and are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document** > **Refactoring** menu:

- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.
- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

XML Schema Quick Assist Support

The *Quick Assist support* improves the development work flow, offering fast access to the most commonly used actions when you edit schema documents.

The *Quick Assist feature* is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon ( ) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the *quick assist* menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

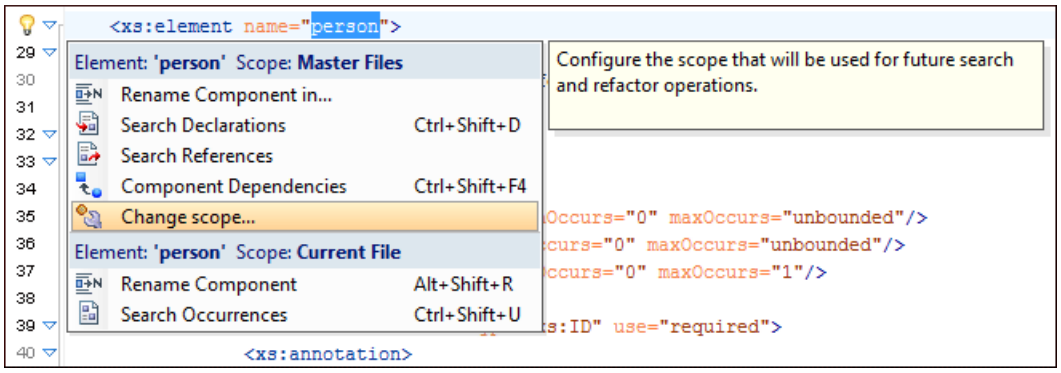

Figure 495: Quick Assist Support

The *Quick Assist* support offers direct access to the following actions:

Rename Component in

Renames the component and all its dependencies.

Search Declarations

Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

Search References

Searches all references of the component in a predefined scope.

Component Dependencies

Searches the component dependencies in a predefined scope.

Change Scope

Configures the scope that will be used for future search or refactor operations.

Rename Component

Allows you to rename the current component in-place.

Search Occurrences

Searches all occurrences of the component within the current file.

For more information about improving schema development using the **Quick Assist** action set, watch our video demonstration:

Generating Sample XML Files

Oxygen XML Editor offers support to generate sample XML files both from XML schema 1.0 and XML schema 1.1, depending on the XML schema version set in ***XML Schema*** *preferences page*.

To generate sample XML files from an XML Schema, use the **Generate Sample XML Files** action from the **Tools** menu. This action is also available in the contextual menu of the schema *Design mode*. The action opens the **Generate Sample XML Files** dialog box that allows you to configure a variety of options for generating the files.

The **Generate Sample XML Files** dialog box contains three tabs with various configurable options. Default values for these options can be set in the ***Sample XML Files Generator*** *preferences page*. You can also run the tool from the command line using exported options.

Schema Tab (Generate Sample XML Files Tool)

The **Generate Sample XML Files** tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The first set of options are found in the **Schema** tab.

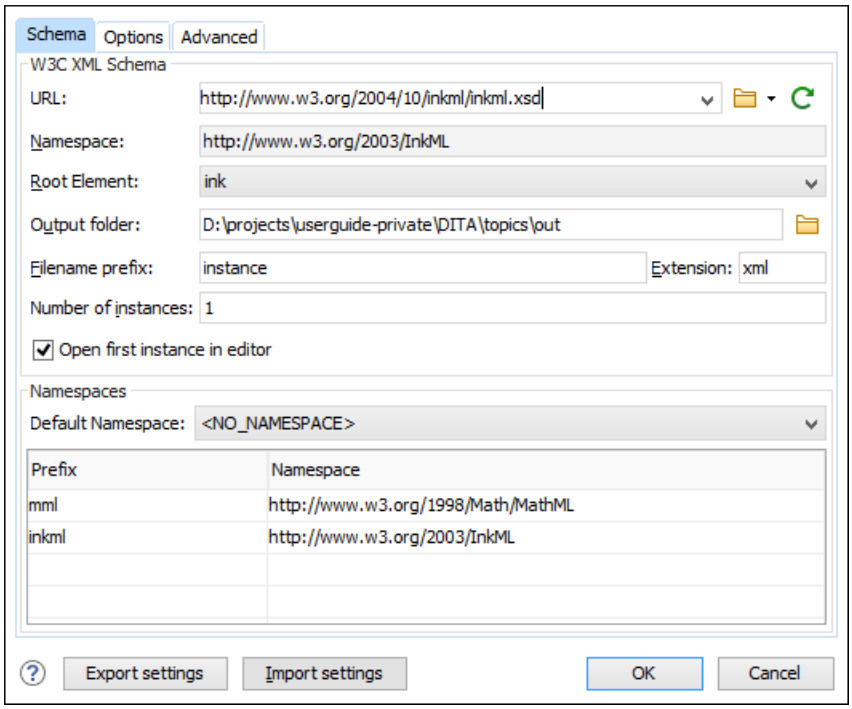

Figure 496: Generate Sample XML Files Dialog Box (Schema Tab)

This tab includes the following options:

URL

Specifies the URL of the Schema location. You can specify the path by using the text field, the history drop-down menu, or the browsing tools in the **Browse** drop-down list.

Namespace

Displays the namespace of the selected schema.

Root Element

After the schema is selected, this drop-down menu is populated with all root candidates gathered from the schema. Choose the root of the output XML documents.

Output folder

Path to the folder where the generated XML instances will be saved.

Filename prefix and Extension

You can specify the prefix and extension for the file name that will be generated. Generated file names have the following format: `prefixN.extension`, where N represents an incremental number from 0 up to the specified ***Number of instances***.

Number of instances

The number of XML files to be generated.

Open first instance in editor

When selected, the first generated XML file is opened in the editor.

Namespaces section

You can specify the **Default Namespace**, as well as the prefixes for the namespaces.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

You can click **OK** at any point to generate the sample XML files.

Options Tab (Generate Sample XML Files Tool)

The **Generate Sample XML Files** tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The **Options** tab allows you to set specific options for namespaces and elements.

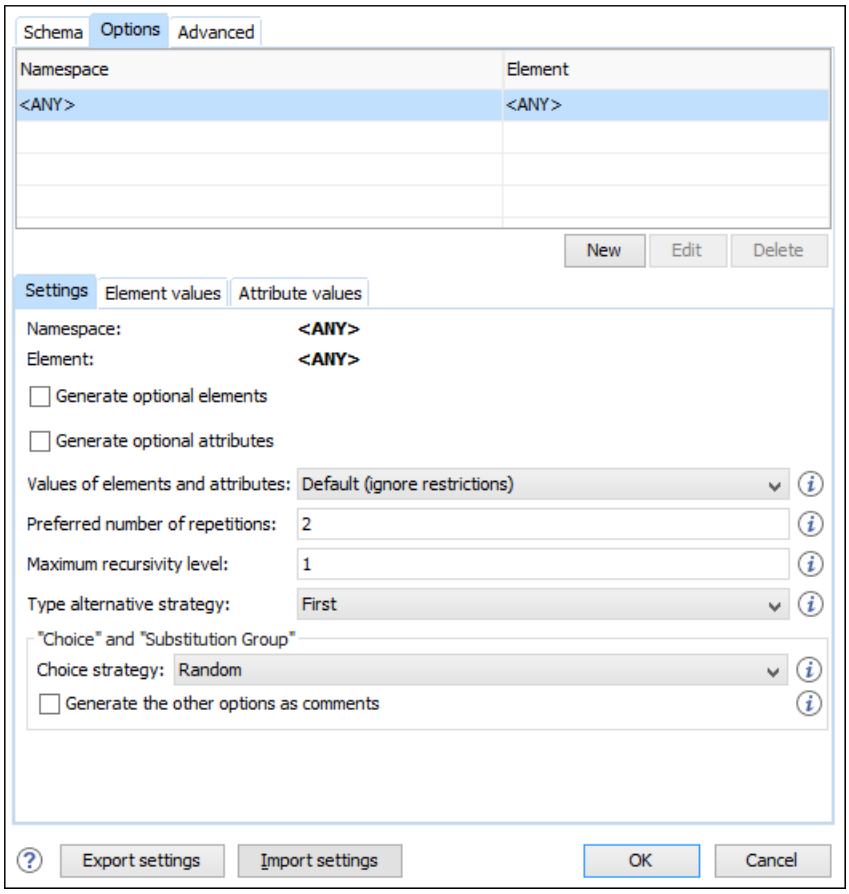

Figure 497: Generate Sample XML Files Dialog Box (Options Tab)

This tab includes the following options:

Namespace / Element table

Allows you to set a namespace for each element name that appears in an XML document instance. The following prefix-to-namespace associations are available:

- All elements from all namespaces (<ANY> - <ANY>). This is the default setting.
- All elements from a specific namespace.
- A specific element from a specific namespace.

Settings subtab

Namespace

Displays the namespace specified in the table at the top of the dialog box.

Element

Displays the element specified in the table at the top of the dialog box.

Generate optional elements

When selected, all elements are generated, including the optional ones (having the `minOccurs` attribute set to 0 in the schema).

Generate optional attributes

When selected, all attributes are generated, including the optional ones (having the `use` attribute set to `optional` in the schema).

Values of elements and attributes

Controls the content of generated attribute and element values. The following choices are available:

- **None** - No content is inserted.
- **Default** - Inserts a default value depending of data type descriptor of the particular element or attribute. The default value can be either the data type name or an incremental name of the attribute or element (according to the global option from the **Sample XML Files Generator** preferences page). Note that type restrictions are ignored when this option is selected. For example, if an element is of a type that restricts an **xs:string** with the **xs:maxLength** facet to allow strings with a maximum length of 3, the XML instance generator tool may generate string element values longer than 3 characters.
- **Random** - Inserts a random value depending of data type descriptor of the particular element or attribute.

  Important: If all of the following are true, the **Generate Sample XML Files** tool outputs invalid values:

  - At least one of the restrictions is a `regexp`.
  - The value generated after applying the regexp does not match the restrictions imposed by one of the facets.

Preferred number of repetitions

Allows you to set the preferred number of repeating elements related to `minOccurs` and `maxOccurs` facets defined in the XML Schema.

- If the value set here is between `minOccurs` and `maxOccurs`, then that value is used.
- If the value set here is less than `minOccurs`, then the `minOccurs` value is used.
- If the value set here is greater than `maxOccurs`, then `maxOccurs` is used.

Maximum recursion level

If a recursion is found, this option controls the maximum allowed depth of the same element.

Type alternative strategy

Used for the `xs:alternative` element from XML Schema 1.1. The possible strategies are:

- **First** - The first valid alternative type is always used.
- **Random** - A random alternative type is used.

Choice strategy

Used for `xs:choice` or `substitutionGroup` elements. The possible strategies are:

- **First** - The first branch of `xs:choice` or the head element of `substitutionGroup` is always used.
- **Random** - A random branch of `xs:choice` or a substitute element or the head element of a `substitutionGroup` is used.

Generate the other options as comments

If selected, generates the other possible choices or substitutions (for `xs:choice` and `substitutionGroup`). These alternatives are generated inside comments groups so you can uncomment and use them later. Use this option with care (for example, on a restricted namespace and element) as it may generate large result files.

Element values subtab

Allows you to add values that are used to generate the content of elements. If there are multiple values, then the values are used in a random order.

Attribute values subtab

Allows you to add values that are used to generate the content of attributes. If there are multiple values, then the values are used in a random order.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

You can click **OK** at any point to generate the sample XML files.

Advanced Tab (Generate Sample XML Files Tool)

The **Generate Sample XML Files** tool includes a dialog box that allows you to configure a variety of options for generating the XML files. The **Advanced** tab allows you to set some options in regards to output values and performance.

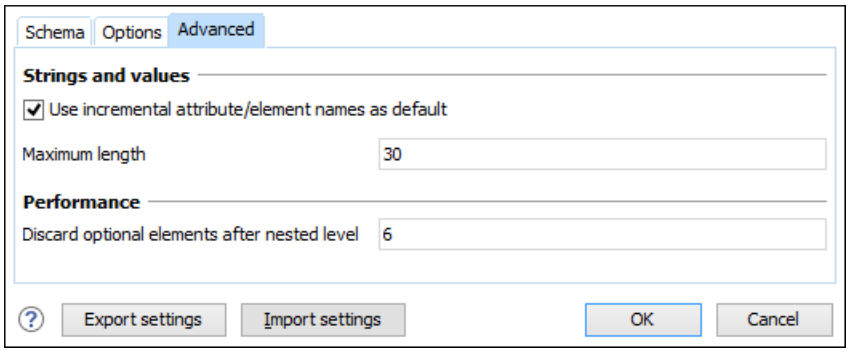

Figure 498: Generate Sample XML Files Dialog Box (Advanced Tab)

This tab includes the following options:

Use incremental attribute / element names as default

If selected, the value of an element or attribute starts with the name of that element or attribute. For example, for an a element the generated values are: a1, a2, a3, and so on. If not selected, the value is the name of the type of that element / attribute (for example: `string`, `decimal`, etc.)

Maximum length

The maximum length of string values generated for elements and attributes.

Discard optional elements after nested level

The optional elements that exceed the specified nested level are discarded. This option is useful for limiting deeply nested element definitions that can quickly result in very large XML documents.

Export settings

Use this button to save the current settings for future use.

Import settings

Use this button to load previously exported settings.

Running the Generate Sample XML Files Tool from the Command Line

The **Generate Sample XML Files** tool can be also used from command line by running the script called `xmlGenerator.bat` (on Windows) / `xmlGenerator.sh` (on Mac OS X / Unix / Linux) located in the Oxygen XML Editor installation folder. The parameters can be set in the dialog box, exported to an XML file on disk with the **Export settings** button, and then reused from command line. With the exported settings file, you can generate the same XML instances from the command line as from the dialog box. For example:

```
xmlGenerator.bat path_of_CFG_file
```

The script can be integrated in an external batch process launched from the command line. The command line parameter of the script is the relative path to the exported XML settings file. The files specified with relative paths in the exported XML settings will be made absolute relative to the folder where the script is run.

The following example shows such an XML configuration file:

```
<settings>
    <schemaSystemId>http://www.w3.org/2001/XMLSchema.xsd</schemaSystemId>
    <documentRoot>schema</documentRoot>
    <outputFolder>D:\projects\output</outputFolder>
    <filenamePrefix>instance</filenamePrefix>
    <filenameExtension>xml</filenameExtension>
    <noOfInstances>1</noOfInstances>
    <openFirstInstance>true</openFirstInstance>
    <defaultNamespace>&lt;NO_NAMESPACE></defaultNamespace>
    <element namespace="&lt;ANY>" name="&lt;ANY>">
        <generateOptionalElements>false</generateOptionalElements>
        <generateOptionalAttributes>false</generateOptionalAttributes>
        <valuesForContentType>DEFAULT</valuesForContentType>
        <preferredNumberOfRepetitions>2</preferredNumberOfRepetitions>
```

```
        <maximumRecursivityLevel>1</maximumRecursivityLevel>
        <choicesAndSubstitutions strategy="RANDOM"
                generateOthersAsComments="false"/>
        <attribute namespace="&lt;ANY>"
                name="&lt;ANY>">
            <attributeValue>attrValue1</attributeValue>
            <attributeValue>attrValue2</attributeValue>
        </attribute>
    </element>
    <element namespace="&lt;NO_NAMESPACE>"
            name="&lt;ANY>">
        <generateOptionalElements>true</generateOptionalElements>
        <generateOptionalAttributes>true</generateOptionalAttributes>
        <valuesForContentType>DEFAULT</valuesForContentType>
        <preferredNumberOfRepetitions>2</preferredNumberOfRepetitions>
        <maximumRecursivityLevel>1</maximumRecursivityLevel>
        <choicesAndSubstitutions strategy="RANDOM"
                generateOthersAsComments="true"/>
        <elementValue>value1</elementValue>
        <elementValue>value2</elementValue>
        <attribute namespace="&lt;ANY>"
                name="&lt;ANY>">
            <attributeValue>attrValue1</attributeValue>
            <attributeValue>attrValue2</attributeValue>
        </attribute>
    </element>
</settings>
```

Generating Documentation for an XML Schema

Oxygen XML Editor can generate detailed documentation for the components of an XML Schema in HTML, PDF, DocBook, or other custom formats. You can select the components and the level of detail. The components are hyperlinked in both HTML and DocBook documents.

Note: You can generate documentation for both XML Schema version 1.0 and 1.1.

To generate documentation for an XML Schema document, select **XML Schema Documentation** from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project*** *view*.

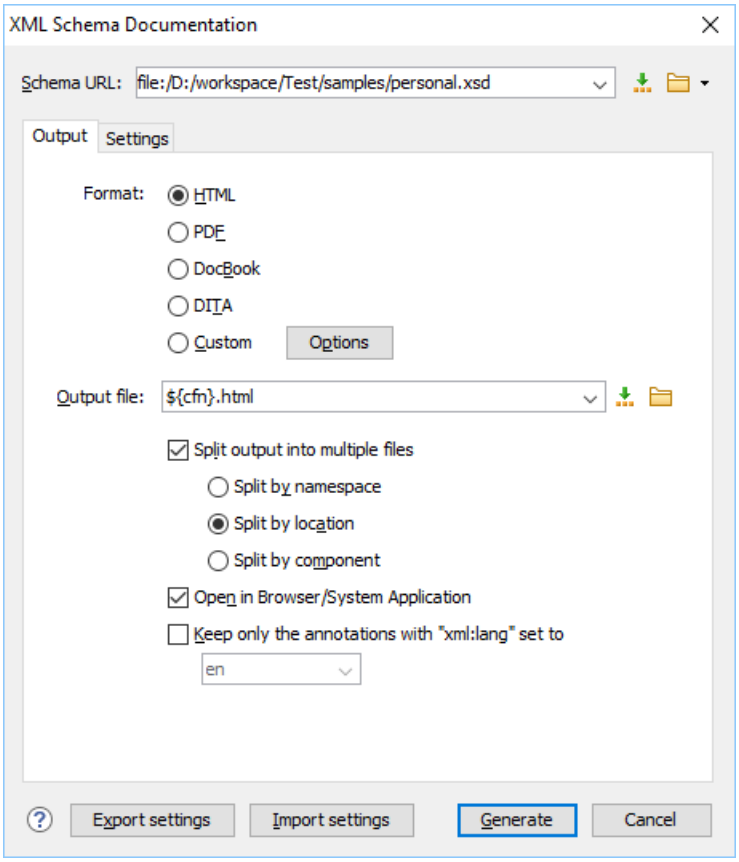

Figure 499: XML Schema Documentation Dialog Box

The **Schema URL** field of the dialog box must contain the full path to the XML Schema (XSD) file for which you want to generate documentation. The schema may be a local or a remote file. You can specify the path to the schema by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in *HTML output format*.
  - **PDF** - The documentation is generated in *PDF output format*.
  - **DocBook** - The documentation is generated in *DocBook output format*.
  - **DITA** - The documentation is generated in *DITA output format*.
  - **Custom** - The documentation is generated in a *custom output format*, allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.
- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type. For DITA and DocBook documents, this option appears as **Open in Editor** and the result will be opened in Oxygen XML Editor (in the current editor).

  Note: To set the browser or system application that will be used, *open the **Preferences** dialog box (**Options > Preferences**)*, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.
- **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `xml:lang` attribute set to the selected language. If you choose a primary language code (for example, **en** for English), this includes all its possible variations (**en-us**, **en-uk**, etc.).

Settings Tab

When you generate documentation for an XML schema you can choose what components to include in the output and the details to be included in the documentation.

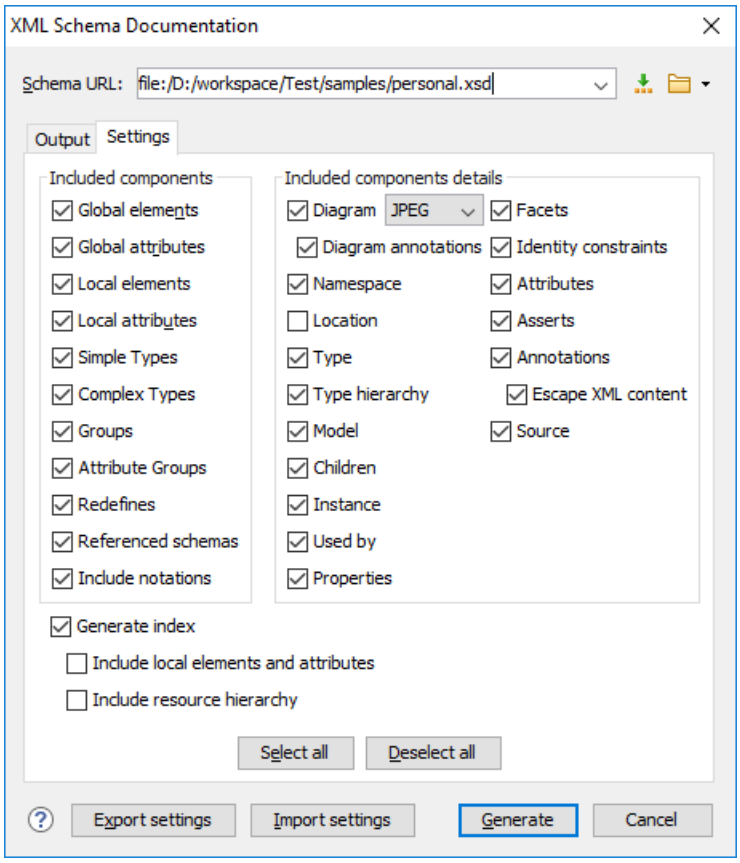

Figure 500: Settings Tab of the XML Schema Documentation Dialog Box

The **Settings** tab allows you to choose whether or not to include the following components: **Global elements**, **Global attributes**, **Local elements**, **Local attributes**, **Simple Types**, **Complex Types**, **Groups**, **Attribute Groups**, **Redefines**, **Referenced schemas**, **Include notations**.

You can choose whether or not to include the following other details:

- **Diagram** - Displays the diagram for each component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section. The generated diagrams are dependent on the options from the *Schema Design Properties* page.
  - **Diagram annotations** - This option controls whether or not the annotations of the components presented in the diagram sections are included.
- **Namespace** - Displays the namespace for each component.
- **Location** - Displays the schema location for each component.
- **Type** - Displays the component type if it is not an anonymous one.
- **Type hierarchy** - Displays the types hierarchy.
- **Model** - Displays the model (sequence, choice, all) presented in BNF form. The separator characters that are used depend upon the information item used:
  - `xs:all` - Its children will be separated by space characters.
  - `xs:sequence` - Its children will be separated by comma characters.
  - `xs:choice` - Its children will be separated by / characters.
- **Children** - Displays the list of component's children.
- **Instance** - Displays an XML instance generated based on each schema element.
- **Used by** - Displays the list of all the components that reference the current one. The list is sorted by component type and name.
- **Properties** - Displays some of the component's properties.
- **Facets** - Displays the facets for each simple type

- **Identity constraints** - Displays the identity constraints for each element. For each constraint there are presented the name, type (unique, key, keyref), reference attribute, selector and field(s).
- **Attributes** - Displays the attributes for the component. For each attribute there are presented the name, type, fixed or default value, usage and annotation.
- **Asserts** - Displays the **assert** elements defined in a complex type. The test, XPath default namespace, and annotation are presented for each assert.
- **Annotations** - Displays the annotations for the component. If you choose **Escape XML Content**, the XML tags are present in the annotations.
- **Source** - Displays the text schema source for each component.
- **Generate index** - Displays an index with the components included in the documentation.
  - **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
  - **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

Export settings - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same *documentation from the command line interface*.)

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the XML Schema documentation.

Related Information:

Customizing the PDF Output of Generated XML Schema Documentation on page 822

Output Formats for Generating XML Schema Documentation

XML Schema documentation can be generated in HTML, PDF, DocBook, or a custom format. You can choose the format from the *Schema Documentation* dialog box. For the PDF and DocBook formats, the option to split the output in multiple files is not available.

HTML Output Format

The XML Schema documentation generated in HTML format contains images corresponding to the same schema definitions as the ones displayed by *the schema diagram editor*. These images are divided in clickable areas that are linked to the definitions of the names of types or elements. The documentation of a definition includes a **Used By** section with links to the other definitions that reference it. If the **Escape XML Content** option is unchecked, the HTML or XHTML tags used inside the `xs:documentation` elements of the input XML Schema for formatting the documentation text (for example, `<b>`, `<i>`, `<u>`, `<ul>`, `<li>`, etc.) are rendered in the generated HTML documentation.

The generated images format is **PNG**. The image of an XML Schema component contains the graphical representation of that component as it is rendered in *the schema diagram panel of the Oxygen XML Editor XSD editor panel*.

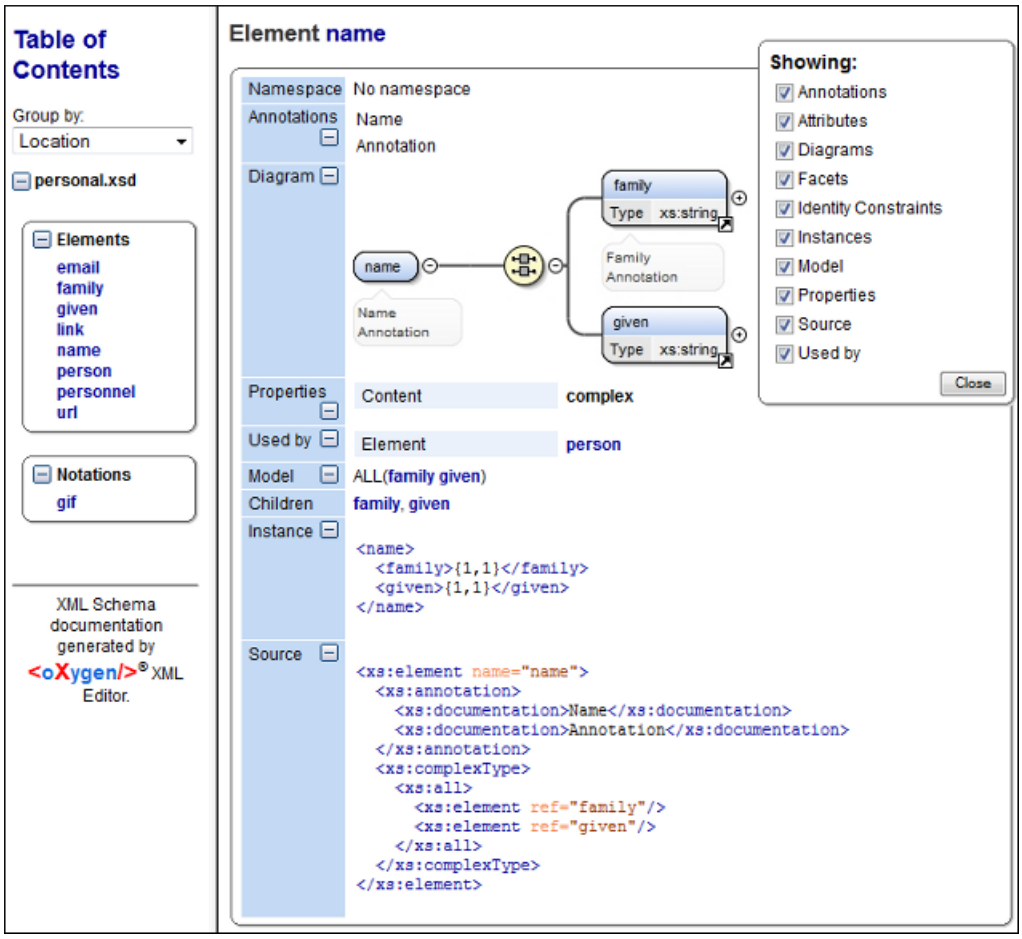

Figure 501: XML Schema Documentation Example

The generated documentation includes a table of contents. You can group the contents by namespace, location, or component type. After the table of contents there is some information about the main, imported, included, and redefined schemas. This information contains the schema target namespace, schema properties (attribute form default, element form default, version), and schema location.

Figure 502: Information About a Schema

If you choose to split the output into multiple files, the table of contents is displayed in the left frame. The contents are grouped in the same mode. If you split the output by location, each file contains a schema description and the components that you have chosen to include. If you split the output by namespace, each file contains information about schemas from that namespace and the list with all included components. If you choose to split the output by component, each file contains information about a schema component.

After the documentation is generated, you can collapse or expand details for some schema components by using the **Showing** options or the **Collapse** or **Expand** buttons.

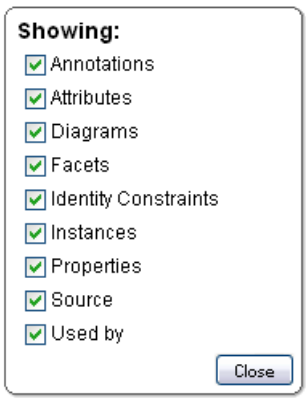

Figure 503: Showing Options

For each component included in the documentation, the section presents the component type follow by the component name. For local elements and attributes, the name of the component is specified as *parent name/component name*. You can easily go to the parent documentation by clicking the parent name.

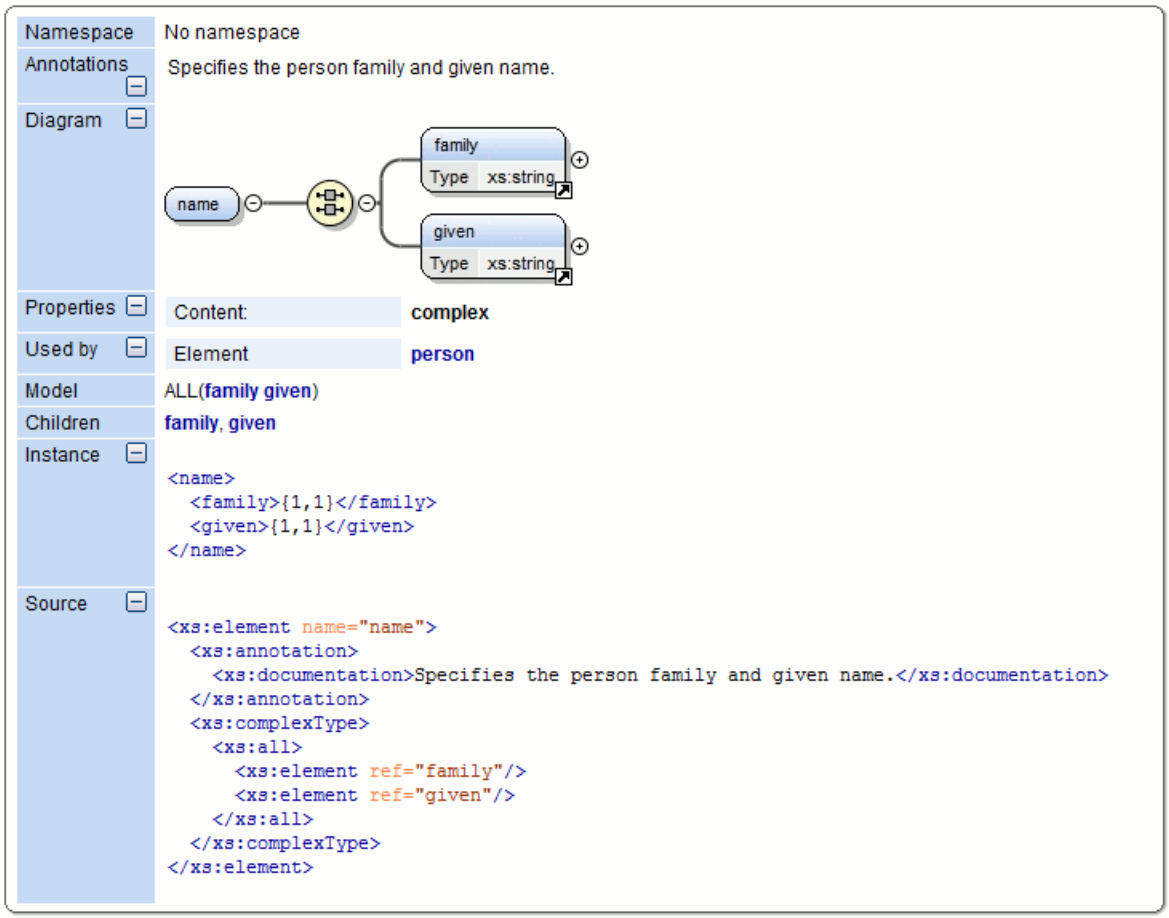

Figure 504: Documentation for a Schema Component

If the schema contains imported or included modules, their dependencies tree is generated in the documentation.

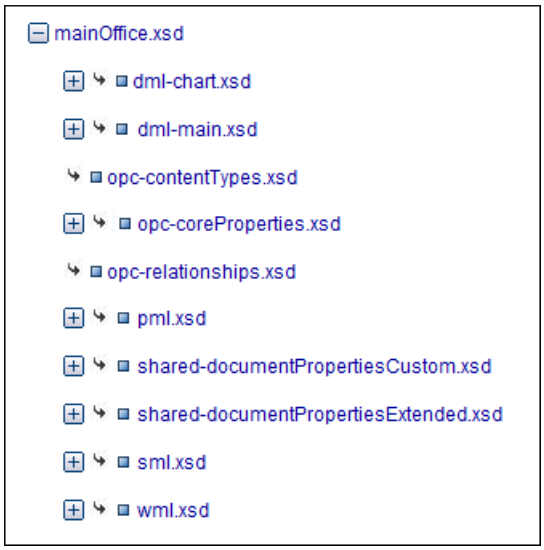

Figure 505: Example: Generated Documentation

PDF Output Format

For the PDF output format, the documentation is generated in DocBook format and a transformation using the FOP processor is applied to obtain the PDF file. To configure the FOP processor, see the *FO Processors* preferences page.

For information about customizing the PDF output, see *Customizing the PDF Output of Generated XML Schema Documentation* on page 822.

DocBook Output Format

If you generate the documentation in DocBook output format, the documentation is generated as a DocBook XML file. You can then apply a *predefined DocBook transformation scenario* (such as, *DocBook PDF* or *DocBook HTML*) on the output file, or *configure your own transformation scenario* to convert it into whatever format you desire.

DITA Output Format

If you generate the documentation in DITA output format, each element of the schema is converted to a DITA *Topic* and all the generated topics are referenced in a *DITA map* file. You can then *apply a predefined DITA transformation scenario* (such as, *DITA Map PDF* or *DITA Map XHTML*), or *configure your own DITA OT transformation scenario* to convert it into whatever format you desire.

Custom Output Format

For the custom format, you can specify a stylesheet to transform the intermediary XML file generated in the documentation process. You have to edit your stylesheet based on the schema `xsdDocSchema.xsd` from `[OXYGEN_INSTALL_DIR]/frameworks/schema_documentation`. You can create a custom format starting from one of the stylesheets used in the predefined HTML, PDF, DocBook, and DITA formats. These stylesheets are available in `[OXYGEN_INSTALL_DIR]/frameworks/schema_documentation/xsl`.

When using a custom format you can also copy additional resources into the output folder and choose to keep the intermediate XML files created during the documentation process.

Important: If you create a custom format for DITA, you must select the ***Split output into multiple files*** *option in the* ***Output*** *tab* and choose **Split by component.**

Customizing the PDF Output of Generated XML Schema Documentation

To customize the PDF output of the generated XML Schema documentation, use the following procedure:

1. Customize the `[OXYGEN_INSTALL_DIR]/frameworks/schema_documentation/xsl/xsdDocDocbook.xsl` stylesheet to include the content that you want to add in the PDF output. Add the

content in the XSLT template with the `match="schemaDoc"` attribute between the `info` and `xsl:apply-templates` elements, as commented in the following example:

```
<info>
    <pubdate><xsl:value-of select="format-date(current-date(),
        '[Mn] [D], [Y]', 'en', (), ())"/></pubdate>
</info>
   <!-- Add the XSLT template content with match="schemaDoc" attribute here -->
<xsl:apply-templates select="schemaHierarchy"/>
```

Note: The content that you insert here has to be wrapped in DocBook markup.

2. Create an intermediary file that holds the content of your XML Schema documentation.
   a. Go to **Tools** > **Generate Documentation** > **XML Schema Documentation**.
   b. Select **Custom** for the output format and click the **Options** button.
   c. In the **Custom format options** dialog box, do the following:
      a. Enter the customized stylesheet in the **Custom XSL** field (*[OXYGEN_INSTALL_DIR]*`/frameworks/schema_documentation/xsl/xsdDocDocbook.xsl`).
      b. Select the **Copy additional resources to the output folder** option and leave the default selection in the **Resources** field.
      c. Click **OK**.
   d. When you return to the **XML Schema Documentation** dialog box, just press the **Generate** button to generate a DocBook XML file with an intermediary form of the Schema documentation.
3. Create the final PDF document.
   a. Use the **Configure Transformation Scenario(s)** action from the toolbar or the **Document** > **Transformation** menu, click **New**, and select **XML transformation with XSLT**.
   b. In the **New Scenario** dialog box, go to the **XSL URL** field and choose the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/oxygen/xsdDocDocbookCustomizationFO.xsl` file.
   c. Go to the **FO Processor** tab and select the **Perform FO Processing** and **XSLT result as input** options.
   d. Go to the **Output** tab and select the directory where you want to store the XML Schema documentation output and click **OK**.
   e. Click **Apply Associated**.

Tip: If you want your modifications to be permanent so that you can simply select the PDF output format in the **XML Schema Documentation** dialog box, rather than configuring a custom format each time you generate this documentation, follow this procedure:

1. Create a *JAR* or ZIP file that includes the modified stylesheet (customized in step 1 above), placed in the following directory structure: `builtin/documentation/schema_documentation/xsdDocDocbook.xsl`.
2. Create a new directory named `endorsed` inside the *[OXYGEN_INSTALL_DIR]*`/lib` directory and place the created *JAR* or ZIP file inside it.
3. Restart Oxygen XML Editor and the PDF output format will now use your customized stylesheet.

Generating XML Schema Documentation From the Command-Line Interface

You can export the settings of the ***XML Schema Documentation*** *dialog box* to an XML file by pressing the **Export settings** button. With the exported configuration file, you can generate the same documentation from the command-line interface by running the following script:

- `schemaDocumentation.bat` on Windows.
- `schemaDocumentation.sh` on OS X / Linux.

The script is located in the Oxygen XML Editor installation folder. The script can be integrated in an external batch process launched from the command-line interface. The script accepts a variety command line arguments that allow you to configure the documentation.

The accepted syntax and arguments are as follows:

`schemaDocumentation schemaFile [ [-cfg:configFile] | [ [-out:outputFile] [-format:<value>] [-xsl:<xslFile>] [-split:<value>] [-openInBrowser:<value>] ] | --help | -help | --h | -h ]`

schemaFile

The XML Schema file.

-cfg:configfile

The exported configuration file. It contains the output file, output format options, split method, and some advanced options regarding the included components and components details. If an external configuration file is specified, all other supplied arguments except for the XML Schema file will be ignored.

-out:outputFile

The file where the generated documentation will be saved. By default, it is the name of the schema file with an *html* extension.

-format:<value>

The output format type used when generating the documentation. Possible values are as follows:

- `html` - To generate documentation in HTML format.
- `pdf` - To generate documentation in PDF format.
- `docbook` - To generate documentation in DocBook format.
- `custom` - To generate documentation in a custom format.

-xsl:<xslFile>

The XSL file to be applied on the intermediate XML format. If there is no XSL file provided, the result will be in the HTML format.

-split:<value>

The split method used when generating the documentation. Splitting is recommended for large schemas. Possible values are as follows:

- `none` (default value) - To generate one single output file.
- `namespace` - To generate an output file for every namespace in the schema.
- `component` - To generate an output file for every component in the schema.
- `location` - To generate an output file for every schema location.

-openInBrowser:<value>

Opens the result of the transformation in a browser or system application. Possible values are `true` or `false` (default value).

--help | -help | --h | -h

Displays the available options.

Example:

Example of the script in a Windows command line:

```
schemaDocumentation example.xsd -out:schemaDocumentation.html
    -format:custom -xsl:example.xsl -split:namespace
```

Converting Schema to Another Schema Language

The **Generate/Convert Schema** tool allows you to convert a DTD or Relax NG (full or compact syntax) schema or a set of XML files to an equivalent XML Schema, DTD or Relax NG (full or compact syntax) schema. Where perfect equivalence is not possible due to limitations of the target language, Oxygen XML Editor generates an approximation of the source schema. Oxygen XML Editor uses *Trang multiple format converter* to perform the actual schema conversions.

To use this tool, select the **Generate/Convert Schema (Alt + Shift + C (Command + Alt + C on OS X))** action from the **Tools** menu or from the **Open with** submenu when invoking the contextual menu in the ***Project** view*. This action opens the **Generate/Convert Schema** dialog box that allows you to configure various options for conversion.

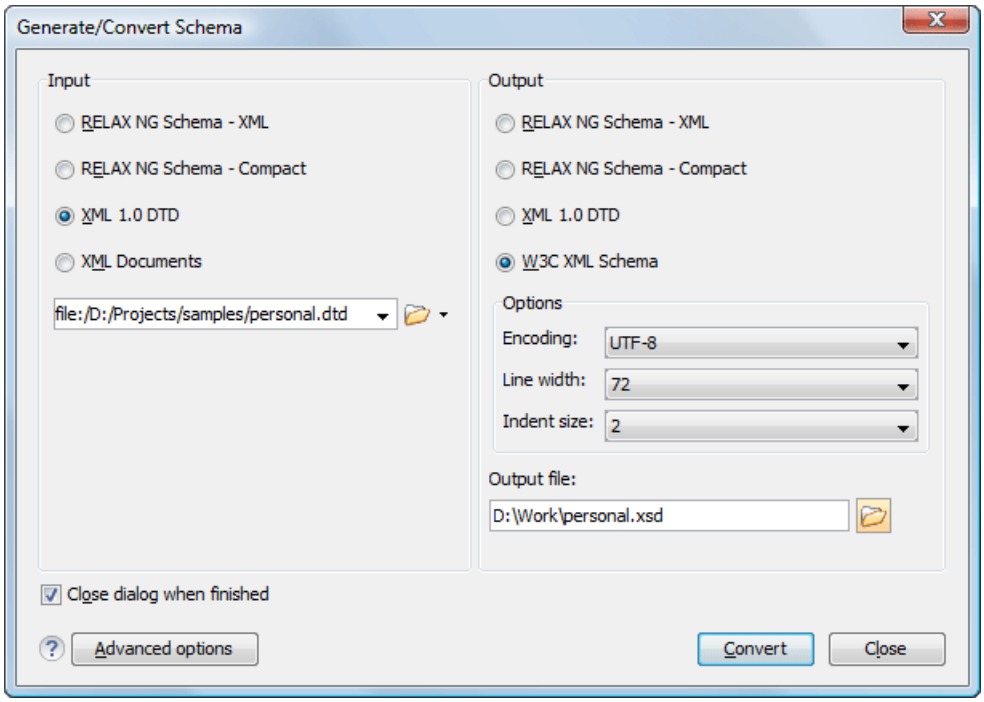

Figure 506: Generate/Convert Schema Dialog Box

The **Generate/Convert Schema** dialog box includes the following options:

Input section

Allows you to select the language of the source schema. If the conversion is based on a set of XML files, rather than just a single XML file, select the **XML Documents** option and use the file selector to add the XML files involved in the conversion.

Output section

Allows you to select the language of the target schema.

Options

You can choose the **Encoding**, the maximum **Line width**, and the **Indent size** (in number of spaces) for one level of indentation.

Output file

Specifies the path for the output file that will be generated.

Close dialog when finished

If you deselect this option, the dialog box will remain opened after the conversion so that you can easily continue to convert more files.

Advanced options

If you select **XML 1.0 DTD** for the input, you can click this button to access more advance options to further fine-tune the conversion. The following advanced options are available:

XML 1.0 DTD Input section

These options apply to the source DTD:

- **xmlns** - Specifies the default namespace, that is the namespace used for unqualified element names.
- **attlist-define** - Specifies how to construct the name of the definition representing an attribute list declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **colon-replacement** - Replaces colons in element names with the specified chars when constructing the names of definitions used to represent the element declarations and attribute list declarations in the DTD.

- **any-name** - Specifies the name of the definition generated for the content of elements declared in the DTD as having a content model of ANY.
- **element-define** - Specifies how to construct the name of the definition representing an element declaration from the name of the element. The specified value must contain exactly one percent character. This percent character is replaced by the name of element (after colon replacement) and the result is used as the name of the definition.
- **annotation-prefix** - Default values are represented using an annotation attribute `prefix:defaultValue` where prefix is the specified value and is bound to `http://relaxng.org/ns/compatibility/annotations/1.0` as defined by the RELAX NG DTD Compatibility Committee Specification. By default, the conversion engine will use a for prefix unless that conflicts with a prefix used in the DTD.
- **inline-attlist** - Instructs the application not to generate definitions for attribute list declarations, but instead move attributes declared in attribute list declarations into the definitions generated for element declarations. This is the default behavior when the output language is XSD.
- **strict-any** - Preserves the exact semantics of *ANY* content models by using an explicit choice of references to all declared elements. By default, the conversion engine uses a wildcard that allows any element
- **generate-start** - Specifies whether or not the conversion engine should generate a start element. DTD's do not indicate what elements are allowed as document elements. The conversion engine assumes that all elements that are defined but never referenced are allowed as document elements.
- **xmlns mappings** table - Each row specifies the prefix used for a namespace in the input schema.

W3C XML Schema Output section

This section is available if you select **W3C XML Schema** for the output.

- **disable-abstract-elements** - Disables the use of abstract elements and substitution groups in the generated XML Schema. This can also be controlled using an annotation attribute.
- **any-process-contents** - One of the values: strict, lax, skip. Specifies the value for the `processContents` attribute of any elements. The default is skip (corresponding to RELAX NG semantics) unless the input format is DTD, in which case the default is strict (corresponding to DTD semantics).
- **any-attribute-process-contents** - Specifies the value for the `processContents` attribute of `anyAttribute` elements. The default is skip (corresponding to RELAX NG semantics).

Converting Database to XML Schema

Oxygen XML Editor includes a tool that allows you to create an XML Schema from the structure of a database.

To convert a database structure to an XML Schema, use the following procedure:

1. Select the **Convert DB Structure to XML Schema** action from the **Tools** menu.

   Result: The **Convert DB Structure to XML Schema** dialog box is opened and your current database connections are displayed in the **Connections** section.
2. If the database source is not listed, click the **Configure Database Sources** button to open the ***Data Sources** preferences page* where you can configure data sources and connections.
3. In the **Format for generated schema** section, select one of the following formats:
   - **Flat schema** - A flat structure that resembles a tree-like view of the database without references to elements.
   - **Hierarchical schema** - Display the table dependencies visually, in a type of tree view where dependent tables are shown as indented child elements in the content model. Select this option if you want to configure the database columns of the tables to be converted.
4. Click **Connect**.

   Result: The database structure is listed in the **Select database tables** section according to the format you chose.
5. Select the database tables that you want to be included in the XML Schema.
6. If you selected **Hierarchical schema** for the format, you can configure the database columns.

   a. Select the database column you want to configure.

b. In the **Criterion** section you can choose to convert the selected database column as an **Element**, **Attribute**, or to be **Skipped** in the resulting XML Schema.
c. You can also change the name of the selected database column by changing it in the **Name** text field.

7. Click **Generate XML Schema**.

Result: The database structure is converted to an XML Schema and it is opened for viewing and editing.

Flatten an XML Schema

You can organize an XML schema linked by `xs:include` and `xs:import` statements on several levels. In some cases, working on such a schema as if it were a single file is more convenient than working on multiple files separately. The **Flatten Schema** operation allows you to flatten an entire hierarchy of XML schemas. Starting with the main XML schema, Oxygen XML Editor calculates its hierarchy by processing the `xs:include` and `xs:import` statements.

The **Flatten Schema** action is available from the **Tools** menu or the contextual menu in **Text** mode. The action opens the **Flatten Schema** dialog box that allows you to configure the operation.

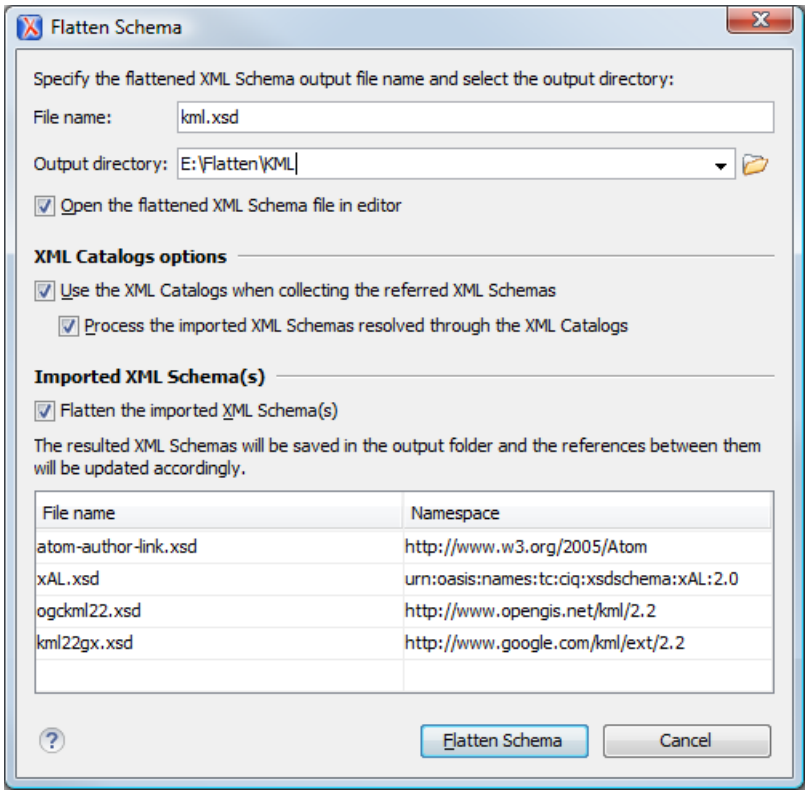

Figure 507: Flatten Schema Dialog Box

For the main schema file and for each imported schema, a new flattened schema is generated in the specified output folder. These schemas have the same name as the original ones.

Note: If necessary, the operation renames the resulted schemas to avoid duplicated file names.

A flattened XML schema is obtained by recursively adding the components of the included schemas into the main one. This means Oxygen XML Editor replaces the `xs:include`, `xs:redefine`, and `xs:override` elements with the ones coming from the included files.

Options in the Flatten Schema Dialog Box

The following options are available in the **Flatten Schema** dialog box:

File name

The name of the output file.

Output directory

The path of the output directory where the flattened schema file will be saved.

Open the flattened XML Schema file in editor

Opens the main flattened schema in the editing area after the operation completes.

Use the XML Catalogs when collecting the referenced XML Schemas

Enables the imported and included schemas to be resolved through the available *XML Catalogs*.

Note: Changing this option triggers the recalculation of the dependencies graph for the main schema.

Process the imported XML Schemas resolved through the XML Catalogs

Specifies whether or not the imported schemas that were resolved through an *XML Catalog* are also processed.

Flatten the imported XML Schema(s)

Specifies whether or not the imported schemas are flattened.

Note: For the schemas skipped by the flatten operation, no files are created in the output folder and the corresponding import statements remain unchanged.

Flatten Schema from the Command Line

The **Flatten Schema** tool can be also ran from command line by using the following command:

- `flattenSchema.bat` on Windows
- `sh flattenSchema.sh` on OS X and Linux

The command line accepts the following parameters:

- `-in:inputSchemaURL` - The input schema URL.
- `-outDir:outputDirectory` - The directory where the flattened schemas should be saved.
- `-flattenImports:<boolean_value>` - Controls whether or not the imported XML Schemas should be flattened. The default value `true`.
- `-useCatalogs:<boolean_value>` - Controls if the references to other XML Schemas should be resolved through the available *XML Catalogs*. The default value `false`.
- `-flattenCatalogResolvedImports:<boolean_value>` - Controls whether or not the imported schemas that were resolved through the *XML Catalogs* should be flattened. The default value is `true`.

  Note: This option is used only when `-useCatalogs` is set to `true`.
- `-verbose` - Provides information about the current flatten XML Schema operation.
- `--help | -help | --h | -h` - Prints the available parameters for the operation.

Example: Command Line Example for Windows

```
flattenSchema.bat -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
   -outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
      -flattenCatalogResolvedImports:true -verbose
```

Example: Command Line Example for OS X

```
sh flattenSchema.sh -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
    -outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
       -flattenCatalogResolvedImports:true -verbose
```

Example: Command Line Example for Unix/Linux

```
sh flattenSchema.sh -in:http://www.w3.org/MarkUp/SCHEMA/xhtml11.xsd
     -outDir:mySchemas/flattened/xhtml -flattenImports:true -useCatalogs:true
        -flattenCatalogResolvedImports:true -verbose
```

XML Schema Regular Expressions Builder

The XML Schema regular expressions builder allows you to test regular expressions on a fragment of text as they are applied to an XML instance document. Start the tool by selecting **XML Schema Regular Expressions Builder** from the **Tools** menu.

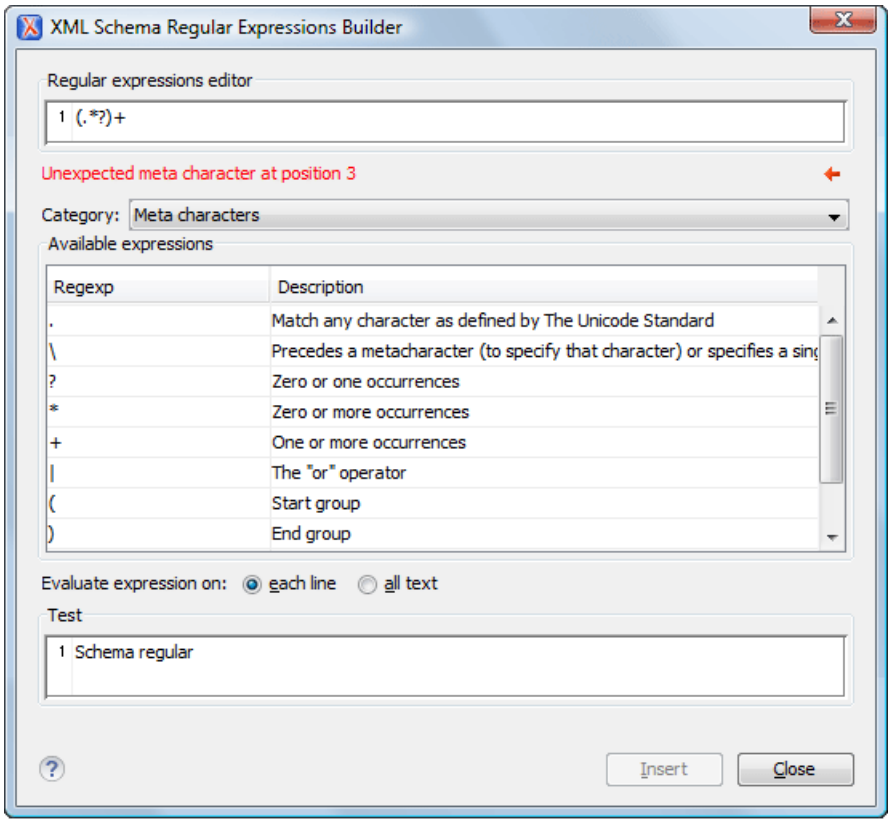

Figure 508: XML Schema Regular Expressions Builder Dialog Box

The dialog box contains the following:

Regular expressions editor

Allows you to edit the regular expression to be tested and used. Content completion is available and presents a list with all the predefined expressions. It is triggered by pressing **Ctrl + Space (Command + Space on OS X)**.

Error display area

If the edited regular expression is incorrect, an error message will be displayed here. The message contains the description and the exact location of the error. Also, clicking the quick navigation button (←) highlights the error inside the regular expression.

Category

You can choose from several categories of predefined expressions. The selected category influences the displayed expressions in the **Available expressions** table.

Available expressions

This table includes the available regular expressions and a short description for each of them. The set of expressions depends on the category selected in the previous **Category** combo box. You can add an expression in the **Regular expressions editor** by double-clicking the expression row in the table. You will notice that in the case of **Character categories** and **Block names**, the expressions are also listed in complementary format.

Evaluate expression on

You can choose between two options:

- **Evaluate expression on each line** - The edited expression will be applied on each line in the **Test** area.
- **Evaluate expression on all text** - The edited expression will be applied on the whole text.

Test

A text editor that allows you to enter a text sample for which the regular expression will be applied. All matches of the edited regular expression will be highlighted.

After editing and testing your regular expression you can insert it in the current editor. The **Insert** button will become active when an editor is opened in the background and there is an expression in the **Regular expressions editor**.

The regular expression builder cannot be used to insert regular expressions in the ***Grid*** *mode* or *schema* ***Design*** *mode*. Accordingly, the **Insert** button will be not available if the current document is edited in these modes.

Note: Some regular expressions may indefinitely block the Java Regular Expressions engine. If the execution of the regular expression does not end in about five seconds, the application displays a dialog box that allows you to interrupt the operation.

XML Schema 1.1

Oxygen XML Editor offers full support for XML Schema 1.1, including:

- XML Documents *Validation* and *Content Completion* based on XML Schema 1.1.
- XML Schema 1.1 *Validation* and *Content Completion*.
- Editing XML Schema 1.1 files in the *Schema* ***Design*** *mode*.
- The *Flatten Schema* action.
- *Resource Hierarchy/Dependencies* and *Refactoring Actions*.
- *Master files*.
- *Generating Documentation for XML Schema 1.1*.
- Support for generating XML instances based on XML Schema.
- Support for validating XML documents with an NVDL schema that contains an XML Schema 1.1 validation step.

  Note: To enable XML Schema 1.1 validation in NVDL, you need to pass the following option to the validation engine to specify the schema version: `http://www.thaiopensource.com/validate/xsd-version` (the possible values are `1.0` or `1.1`.

  Tip: To enable the full XPath expression in assertions and type alternatives, you need to set the `http://www.thaiopensource.com/validate/full-xpath` option.

XML Schema 1.1 is a superset of XML Schema 1.0, that offers lots of new powerful capabilities.

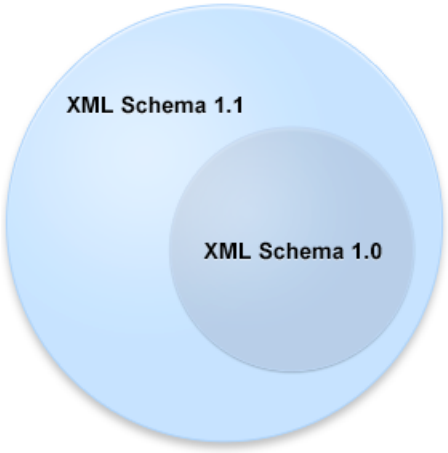

Figure 509: XML Schema 1.1

The significant new features in XSD 1.1 are:

- **Assertions** - Support to define assertions against the document content using XPath 2.0 expressions (an idea borrowed from Schematron).
- **Conditional type assignment** - The ability to select the type of schema an element is validated against, based on the values of the attribute of the element.
- **Open content** - Content models can use the `openContent` element to specify content models with *open content*. These content models allow elements not explicitly mentioned in the content model to appear in the document instance. It is as if wildcards were automatically inserted at appropriate points within the content model. A default may be set that causes all content models to be open unless specified otherwise.

To see the complete list with changes since version 1.0, go to *http://www.w3.org/TR/xmlschema11-1/#ch_specs*.

XML Schema 1.1 is intended to be mostly compatible with XML Schema 1.0 and to have approximately the same scope. It also addresses bug fixes and brings improvements that are consistent with the constraints on scope and compatibility.

Note: An XML document conforming to a 1.0 schema can be validated using a 1.1 validator, but an XML document conforming to a 1.1 schema may not validate using a 1.0 validator.

If you are constrained to use XML Schema 1.0 (for example, if you develop schemas for a server that uses an XML Schema 1.0 validator that cannot be updated), change the default XML Schema version to 1.0. If you keep the default XML Schema version set to 1.1, the *Content Completion Assistant* presents XML Schema 1.1 elements that you can insert accidentally in an 1.0 XML Schema. So even if you make a document invalid conforming with XML Schema 1.0, the validation process does not signal any issues.

To change the default XML Schema version, *open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **XML** > **XML Parser** > **XML Schema**.

For more information about the XML Schema 1.1 support, watch our video demonstration:

Related Information:
Setting the XML Schema Version on page 831

Setting the XML Schema Version

Oxygen XML Editor lets you set the version of the XML Schema you are editing either in the **XML Schema** preferences page, or through the versioning attributes. If you want to use the versioning attributes, set the *minVersion* and *maxVersion* attributes, from the *http://www.w3.org/2007/XMLSchema-versioning* namespace, on the *schema* root element.

Note: The versioning attributes take priority over the XML Schema version defined in the preferences page.

Table 68: Using the *minVersion* and *maxVersion* Attributes to Set the XML Schema Version

Versioning Attributes	XML Schema Version
minVersion = "1.0" **maxVersion** = "1.1"	1.0
minVersion = "1.1"	1.1
minVersion = "1.0" **maxVersion** = greater than "1.1"	The XML Schema version defined in the ***XML Schema*** *preferences page*
Not set in the XML Schema document	The XML Schema version defined in the ***XML Schema*** *preferences page*

To change the XML Schema version of the current document, use the **Change XML Schema version** action from the contextual menu. This is available both in the **Text** mode, and in the **Design** mode and opens the **Change XML Schema version** dialog box. The following options are available:

- **XML Schema 1.0** - Inserts the *minVersion* and *maxVersion* attributes on the *schema* element and gives them the values "1.0" and "1.1" respectively. Also, the namespace declaration (*xmlns:vc=http://www.w3.org/2007/XMLSchema-versioning*) is inserted automatically if it does not exist.
- **XML Schema 1.1** - Inserts the *minVersion* attribute on the *schema* element and gives it the value "1.1". Also, removes the *maxVersion* attribute if it exists and adds the versioning namespace (*xmlns:vc=http://www.w3.org/2007/XMLSchema-versioning*) if it is not declared.
- **Default XML Schema version** - Removes the *minVersion* and *maxVersion* attributes from the *schema* element. The default schema version, defined in the **XML Schema** preferences page, is used.

Note: The **Change XML Schema version** action is also available in the informative panel presented at the top of the edited XML Schema. If you close this panel, it will no longer appear until you restore Oxygen XML Editor to its default options.

Oxygen XML Editor automatically uses the version set through the versioning attributes, or the default version if the versioning attributes are not declared, when proposing content completion elements and validating an XML Schema. Also, the XML instance validation against an XML Schema is aware of the versioning attributes defined in the XML Schema.

When you generate sample XML files from an XML Schema, Oxygen XML Editor takes into account the *minVersion* and *maxVersion* attributes defined in the XML Schema.

XML Schema 1.1 on page 830

Editing XQuery Documents

XQuery is the query language for XML and is officially defined by *a W3C Recommendation document*. The many benefits of XQuery include:

- XQuery allows you to work in one common model no matter what type of data you are working with: relational, XML, or object data.
- XQuery is ideal for queries that must represent results as XML, to query XML stored inside or outside the database, and to span relational and XML sources.
- XQuery allows you to create many different types of XML representations of the same data.
- XQuery allows you to query both relational sources and XML sources, and create one XML result.

Related Information:

XQuery and Databases on page 1330

XQuery Validation

With Oxygen XML Editor, you can validate your documents before using them in your transformation scenarios. The validation uses the Saxon 9.7.0.19 PE, EE, or HE processor, or you can use some database engines (such as MarkLogic or eXist) if you installed them. Any other XQuery processor that offers an *XQJ API implementation* can also be used. This is in conformance with *the XQuery Working Draft*. The processor is used in two cases: validation of the expression and execution. Although the execution implies a validation, it is faster to check the expression syntactically, without executing it. The errors that occurred in the document are presented in the messages view at the bottom of editor window, with a full description message. As with all error messages, if you click an entry, the line where the error appeared is highlighted.

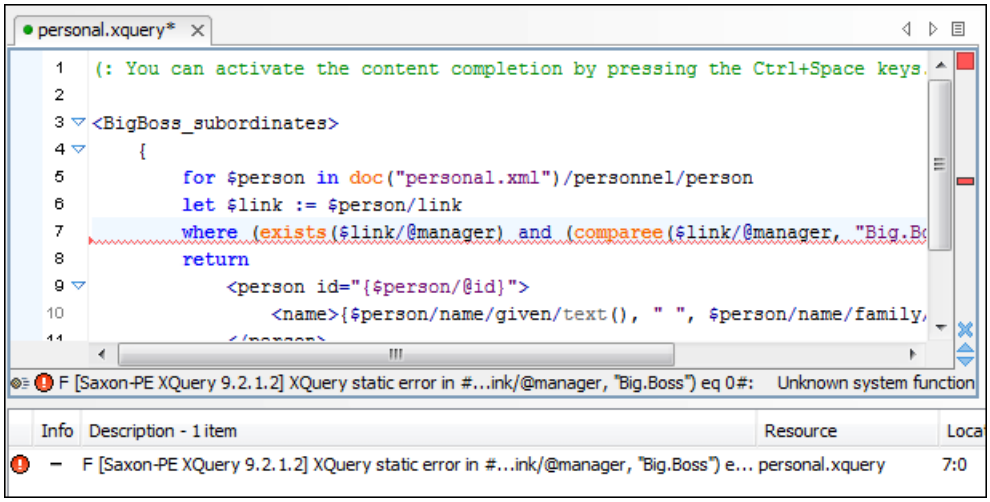

Figure 510: XQuery Validation

Note: If you choose a processor that does not support XQuery validation, Oxygen XML Editor displays a warning when trying to validate.

The **Validation options** button, available in the **Document** > **Validate** menu, allows quick access to the *XQuery options* in the Oxygen XML Editor preferences.

When you open an XQuery document from a connection that supports validation (for example, MarkLogic, or eXist), by default Oxygen XML Editor uses this connection for validation. If you open an XQuery file using a MarkLogic connection, the validation resolves imports better.

Content Completion in XQuery

Oxygen XML Editor provides content completion for keywords and all known XQuery functions and operators. The *Content Completion Assistant* can be manually activated with the **(Ctrl (Meta on Mac OS)+Space)** shortcut. The functions and operators are presented together with a description of the parameters and functionality, depending on the validation or transformation engine.

For some supported database engines such as MarkLogic, eXist, and Berkeley DB, the content completion list offers the specific XQuery functions implemented by that engine. This feature is available when the XQuery file has an associated transformation scenario that uses one of these database engines or the XQuery validation engine is set to one of them via a validation scenario or in the *XQuery Preferences* page. For more information about the support for working with XQuery with regards to databases, see *XQuery and Databases* on page 1330.

The extension functions included in the Saxon engine are available on content completion if one of the following conditions are true:

- The edited file has a transformation scenario associated that uses as transformation engine Saxon 9.7.0.19 PE or Saxon 9.7.0.19 EE.
- The edited file has a validation scenario associated that use as validation engine Saxon 9.7.0.19 PE or Saxon 9.7.0.19 EE.
- The validation engine specified in *Preferences* is Saxon 9.7.0.19 PE or Saxon 9.7.0.19 EE.

If the Saxon namespace (*http://saxon.sf.net*) is mapped to a prefix, the functions are presented using this prefix. Otherwise, the default prefix for the Saxon namespace (`saxon`) is used.

If you want to use a function from a namespace mapped to a prefix, just type that prefix and the content completion displays all the XQuery functions from that namespace. When the default namespace is mapped to a prefix, the XQuery functions from this namespace offered by content completion are also prefixed. Otherwise, only the function name being used.

The content completion pop-up window presents all the variables and functions from both the edited XQuery file and its imports.

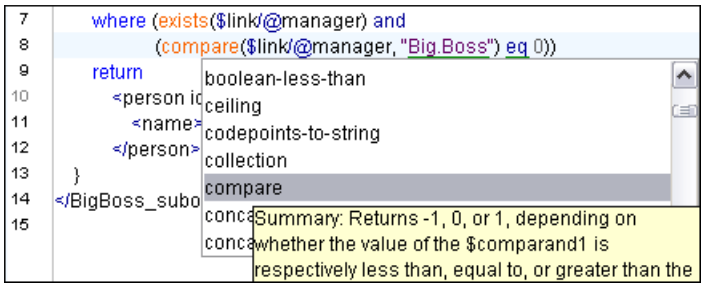

Figure 511: XQuery Content Completion

Syntax Highlighting in XQuery

Oxygen XML Editor supports syntax highlighting in XQuery documents to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for XQuery files, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **XQuery/XPath** section in the top pane.

4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Related Information:
Customize Syntax Highlight colors on page 105

Formatting and Indenting XQuery Documents

Editing XQuery documents may lead to large chunks of content that are not easily readable by human audience. Also, each developer may have a particular way of writing XQuery code. Oxygen XML Editor assists you in maintaining a consistent code writing style with the **Format and Indent** action that is available in the **Document** > **Source** menu and also on the toolbar..

The **Format and Indent** action achieves this by performing the following steps:

- Manages whitespaces, by collapsing or inserting space characters where needed.
- Formats complex expressions on multiple, more readable lines by properly indenting each of them. The amount of whitespaces that form an indent unit is controlled through one of the **Indent with tabs** and **Indent size** options from the ***Format Preferences*** *page*.

Note: These operations can be performed only if your XQuery document conforms with W3C XQuery 1.0, XQuery Update Facility 1.0, and XQuery 3.0 specifications. If the *Format and Indent* operation fails, the document is left unaltered and an error message is presented in the ***Results*** *view*.

Folding in XQuery Documents

In a large XQuery document, the instructions enclosed in the '{' and '}' characters can be collapsed so that only the needed instructions remain in focus. The same *folding features available for XML documents* are also available in XQuery documents.

Figure 512: Folding in XQuery Documents

There is available the action **Go to Matching Bracket** **Ctrl + Shift + G** on contextual menu of XQuery editor for going to matching character when cursor is located at '{' character or '}' character. It helps for finding quickly matching character of current *folding element*.

XQuery Outline View

The XQuery document structure is presented in the **Outline** view. The outline tree presents the list of all the components (namespaces, imports, variables, and functions) from both the edited XQuery file and its imports

and it allows quick access to components. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

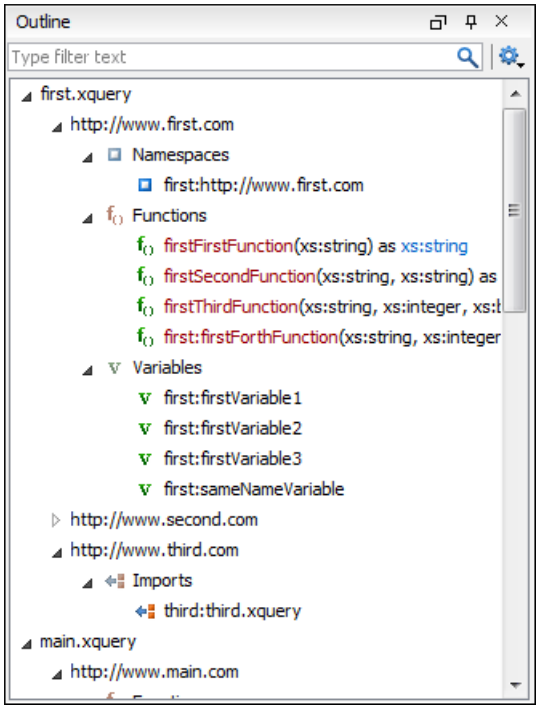

Figure 513: XQuery Outline View

The following actions are available in the **Settings** menu on the **Outline** view toolbar:

Selection update on cursor move

Controls the synchronization between **Outline** view and source document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes performed in the XQuery editor. Selecting one of the components from the **Outline** view also selects the corresponding item in the source document.

Sort

Allows you to alphabetically sort the XQuery components.

Show all components

Displays all collected components starting from the current file. This option is set by default.

Show only local components

Displays the components defined in the current file only.

Group by location/namespace/type

Allows you to group the components by location, namespace, and type. When grouping by namespace, the main XQuery module namespace is presented first in the **Outline** view.

If you know the component name, you can search it in the **Outline** view by typing its name in the filter text field from the top of the view or directly on the tree structure. When you type the component name in the filter text field you can switch to the tree structure using the arrow keys of the keyboard, **(Enter)**, **(Tab)**, **(Shift-Tab)**. To switch from tree structure to the filter text field, you can use **(Tab)**, **(Shift-Tab)**.

Tip: The search filter is case insensitive. The following wildcards are accepted:

- ***** - any string
- **?** - any character
- **,** - patterns separator

If no wildcards are specified, the string to search is used as a partial match.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (*, ?) and separate multiple patterns with commas.

XQuery Builder View

The **XPath/XQuery Builder** view allows you to compose complex XQuery expressions and execute them over the currently edited XML document. You can use the `doc( )` function to specify the source file for which the expressions are executed. When you connect to a database, the expressions are executed over that database. If you are using the **XPath/XQuery Builder** view and the current file is an XSLT document, Oxygen XML Editor executes the expressions over the XML document in the associated scenario.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

The upper part of the view contains the following actions:

XPath version chooser drop-down menu

A drop-down menu that allows you to select the type of the expression you want to execute. You can choose between:

- XPath 1.0 (Xerces-driven)
- XPath 2.0, XPath 2.0SA, XPath 3.0, XPath 3.0SA, XQuery 1.0, XQuery 3.0, Saxon-HE XQuery, Saxon-PE XQuery, or Saxon-EE XQuery (all of them are Saxon-driven)
- Custom connection to XML databases that can execute XQuery expressions

  Note: The results returned by XPath 2.0 SA and XPath 3.0 SA have a location limited to the line number of the start element (there are no column information and no end specified).

  Note: Oxygen XML Editor uses Saxon to execute XPath 3.0 expressions. Since Saxon implements a part of the 3.0 functions, when using a function that is not implemented, Oxygen XML Editor returns a compilation error.

Execute XPath button

Use this button to start the execution of the XPath or XQuery expression you are editing. The result of the execution is displayed in the ***Results*** *view*.

Favorites button

Allows you to save certain expressions that you can later reuse. To add an expression as a favorite, press the star button and enter a name for it. The star turns yellow to confirm that the expression was saved. Expand the drop-down menu next to the star button to see all your favorites. Oxygen XML Editor automatically groups favorites in folders named after the method of execution.

History drop-down menu

Keeps a list of the last 15 executed XPath or XQuery expressions. Use the **Clear history** action from the bottom of the list to remove them.

Settings drop-down menu

Contains the following three options:

- **Update on cursor move** - When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed.
- **Evaluate as you type** - When you select this option, the XPath expression you are composing is evaluated in real time.

  Note: The **Evaluate as you type** option and the automatic validation are disabled when you edit *huge documents* or when the scope is other than **Current file**.
- **Options** - Opens the Preferences page of the currently selected processing engine.

XPath scope menu

Oxygen XML Editor allows you to define a scope for which the XPath operation will be executed. You can choose where the XPath expression will be executed:

- **Current file** - Current selected file only.
- **Project** - All the files in the project.
- **Selected project resources** - The files selected in the project.
- **All opened files** - All files opened in the application.
- **Current DITA Map hierarchy** - All resources referenced in the currently selected *DITA map*, opened in the ***DITA Maps Manager*** *view*.
- **Opened archive** - Files open in the ***Archive Browser*** *view*.
- **Working sets** - The selected *working sets*.

At the bottom of the scope menu the following scope configuration actions are available:

- **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called *working sets*.
- **XPath file filter** - You can filter the files from the selected scope for which the XPath expression will be executed. By default, the XPath expression will be executed only on XML files, but you can also define a set of patterns that will filter out files from the current scope. If you select the **Include archive** option, the XPath expression will be also executed on the files in any archive (including EPUB and DocX) found at the current scope.

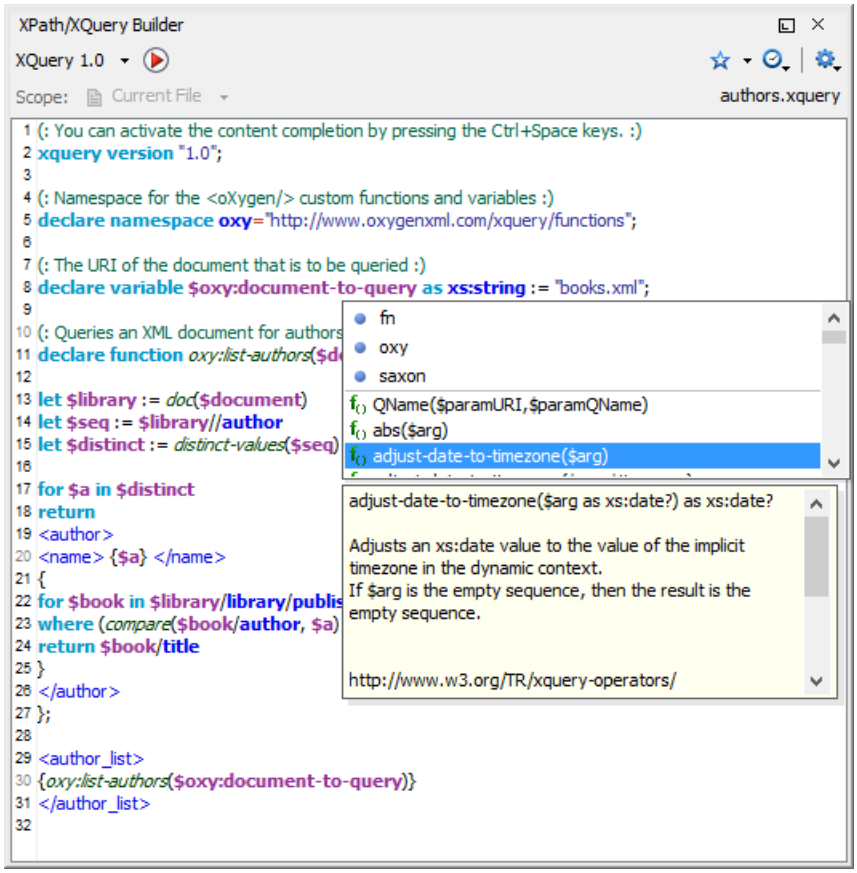

Figure 514: XPath/XQuery Builder View

While you edit an XPath or XQuery expression, Oxygen XML Editor assists you with the following features:

- *Content Completion Assistant* - It offers context-dependent proposals and takes into account the cursor position in the document you are editing. The set of functions proposed by the *Content Completion Assistant* also depends on the engine version. Select the engine version from the drop-down menu available in the toolbar.

- Syntax Highlighting - Allows you to identify the components of an expression. To customize the colors of the components of the expression, *open the **Preferences** dialog box **(Options** > **Preferences)*** and go to ***Editor** > **Syntax Highlight***.
- Automatic validation of the expression as you type.

  Note: When you type invalid syntax a red serrated line underlines the invalid fragments.
- Function signature and documentation balloon, when the cursor is located inside a function.

The usual edit actions (**Cut**, **Copy**, **Paste**, **Select All**, **Undo**, **Redo**) are available in the contextual menu of the top editable part of the view.

XSLT/XQuery Input View

The structure of the XML document associated to the edited XSLT stylesheet, or the structure of the source documents of the edited XQuery is displayed in a tree form in a view called the **XSLT/XQuery Input** view. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu. The tree nodes represent the elements of the documents.

XSLT

If you click a node in the **XSLT/XQuery Input** view, the corresponding template from the stylesheet is highlighted. A node can be dragged from this view and dropped in the editor area for quickly inserting `xsl:template`, `xsl:for-each`, or other XSLT elements that have the `match/select/test` attribute already completed. The value of the attribute is the correct XPath expression that refers to the dragged tree node. This value is based on the current editing context of the drop spot.

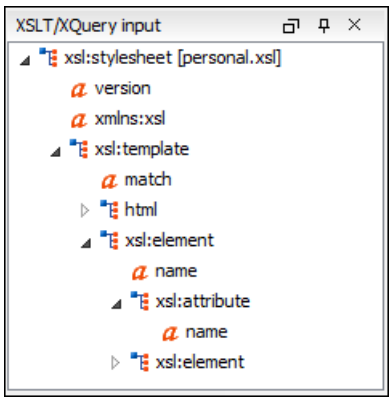

Figure 515: XSLT Input View

XSLT Example:

For the following XML document:

```
<personnel>
    <person id="Big.Boss">
        <name>
            <family>Boss</family>
            <given>Big</given>
        </name>
        <email>chief@oxygenxml.com</email>
        <link subordinates="one.worker"/>
    </person>
    <person id="one.worker">
        <name>
            <family>Worker</family>
            <given>One</given>
        </name>
        <email>one@oxygenxml.com</email>
        <link manager="Big.Boss"/>
    </person>
</personnel>
```

and the following XSLT stylesheet:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
        version="2.0">
```

```
    <xsl:template match="personnel">
        <xsl:for-each select="*">

        </xsl:for-each>
    </xsl:template>
</xsl:stylesheet>
```

if you drag the `given` element and drop it inside the `xsl:for-each` element, the following pop-up menu is displayed:

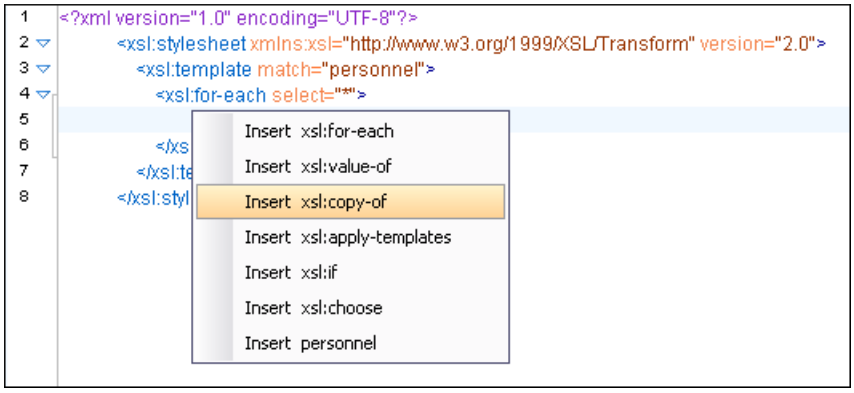

Figure 516: XSLT Input Drag and Drop Pop-up Menu

If you select **Insert xsl:copy-of** (for example), the resulting document will look like this:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="2.0">
    <xsl:template match="personnel">
        <xsl:for-each select="*">
            <xsl:copy-of select="name/given"/>
        </xsl:for-each>
    </xsl:template>
</xsl:stylesheet>
```

Figure 517: XSLT Input Drag and Drop Result

XQuery

You can also use the **XSLT/XQuery Input** view to drag and drop a node into the editing area to quickly insert XQuery expressions.

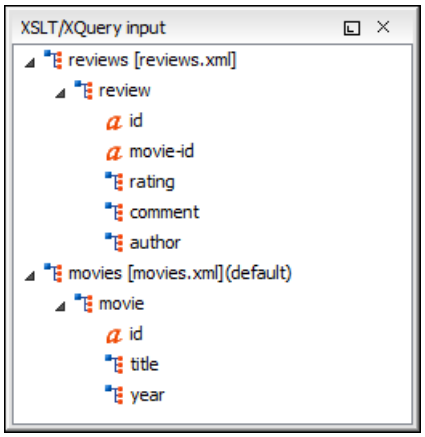

Figure 518: XQuery Input View

XQuery Example:

For the following XML documents:

```
                <movies>
                <movie id="1">
```

```
<title>The Green Mile</title>
<year>1999</year>
</movie>
<movie id="2">
<title>Taxi Driver</title>
<year>1976</year>
</movie>
</movies>
```

```
<reviews>
<review id="100" movie-id="1">
<rating>5</rating>
<comment>It is made after a great Stephen King book.
</comment>
<author>Paul</author>
</review>
<review id="101" movie-id="1">
<rating>3</rating>
<comment>Tom Hanks does a really nice acting.</comment>
<author>Beatrice</author>
</review>
<review id="104" movie-id="2">
<rating>4</rating>
<comment>Robert De Niro is my favorite actor.</comment>
<author>Maria</author>
</review>
</reviews>
```

and the following XQuery:

```
let $review := doc("reviews.xml")
for $movie in doc("movies.xml")/movies/movie
let $movie-id := $movie/@id
return
<movie id="{$movie/@id}">
{$movie/title}
{$movie/year}
<maxRating>
{

}
</maxRating>
</movie>
```

If you drag the **review** element and drop it between the braces, the following pop-up menu is displayed:

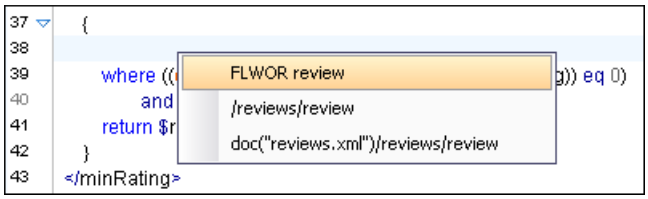

Figure 519: XQuery Input Drag and Drop Pop-up Menu

Select **FLWOR review**, the resulting document will look like this:

```
37      {
38          for $review in doc("reviews.xml")/reviews/review
39          return
40          where ((compare($rev/rating/text(), string($minRating)) eq 0)
41                  and ($rev/@movie-id = $movie/@id))
42          return $rev/author
43      }
```

Figure 520: XQuery Input Drag and Drop Result

Generating HTML Documentation for an XQuery Document

To generate HTML documentation for an XQuery document, use the **XQuery Documentation** dialog box. It is opened with the **XQuery Documentation** action that is available from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project*** *view*.

The dialog box allows you to configure a set of parameters for the process of generating the HTML documentation.

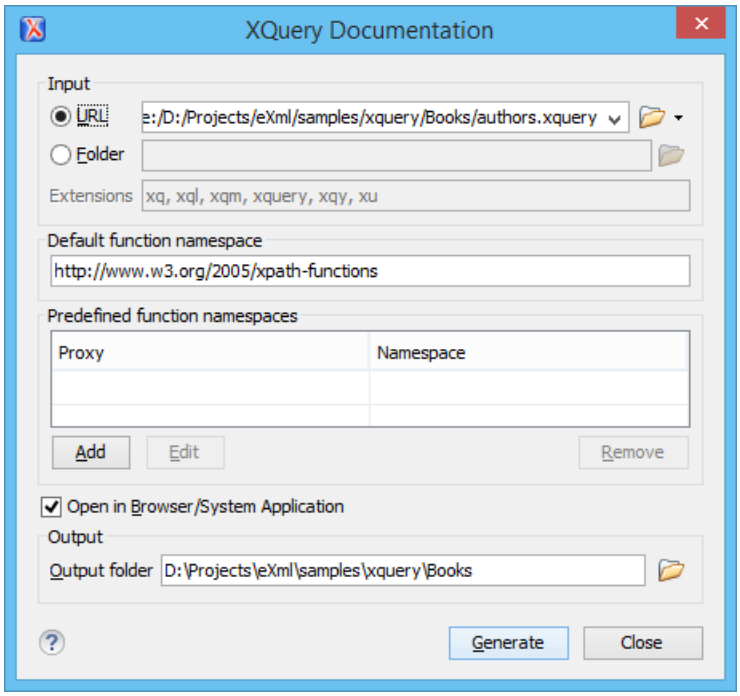

Figure 521: XQuery Documentation Dialog Box

The following options are available:

- **Input** - The full path to the XQuery file must be specified in one of the two fields in this section:
  - **URLFile** - The URL of the file in which you want to generate the documentation.
  - **Folder** - The directory that contains the files for which you want to generate the documentation. You can also specify the XQuery file extensions to be searched for in the specified directory.
- **Default function namespace** - Optional URI for the default namespace for the submitted XQuery.
- **Predefined function namespaces** - Optional, engine-dependent, predefined namespaces that the submitted XQuery refers to. They allow the conversion to generate annotation information to support the presentation component hypertext linking (only if the predefined modules have been loaded into the local xqDoc XML repository).
- **Open in Browser/System Application** - Select this option if you want the result to be opened in the system application associated with that file type.

  Note: To set the browser or system application that will be used, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.
- **Output** - Allows you to specify where the generated documentation is saved on disk.

Transforming XML Documents Using XQuery

XQuery is similar to XSL stylesheets, both being capable of transforming an XML input into another format. You specify the input URL when you *define the transformation scenario*. The result can be saved and opened in the associated application. You can even run a *FO processor* on the output of an XQuery. The transformation scenarios may be shared between many XQuery files, are *exported* together with the XSLT scenarios and can be managed in *the **Configure Transformation Scenario** dialog box* ,or in *the **Scenarios** view*. The transformation can be performed on the XML document specified in the **XML URL** field, or, if this field is empty, the documents referenced from the query expression. The parameters of XQuery transforms must be set in *the **Parameters** dialog box*. Parameters that are in a namespace must be specified using the qualified name (for example, a `param` parameter in the *http://www.oxygenxml.com/ns* namespace must be set with the name `{http://www.oxygenxml.com/ns}param`).

The transformation uses one of the Saxon 9.7.0.19 HE, Saxon 9.7.0.19 PE, Saxon 9.7.0.19 EE processors, a database connection (details can be found in the *Working with Databases* chapter - in the *XQuery transformation* section) or any XQuery processor that provides an XQJ API implementation.

The Saxon 9.7.0.19 EE processor also supports XQuery 3.0 transformations.

Related Information:

XQuery and Databases on page 1330

Display XQuery Result in Sequence View

The result of an XQuery executed on a database can be very large and sometimes only a part of the full result is needed. To avoid the long time necessary for fetching the full result, select the ***Present as a sequence*** *option* in the **Output** tab of the **Edit scenario** dialog box. This option fetches only the first chunk of the result. Clicking the **More results available** label that is displayed at the bottom of the **Sequence** view fetches the next chunk of results.

The size of a chunk can be set with the ***Size limit of Sequence view*** *option*. The **XQuery options** button from the **More results available** label provides a quick access to this option by opening the ***XQuery*** *preferences page* where the option can be modified.

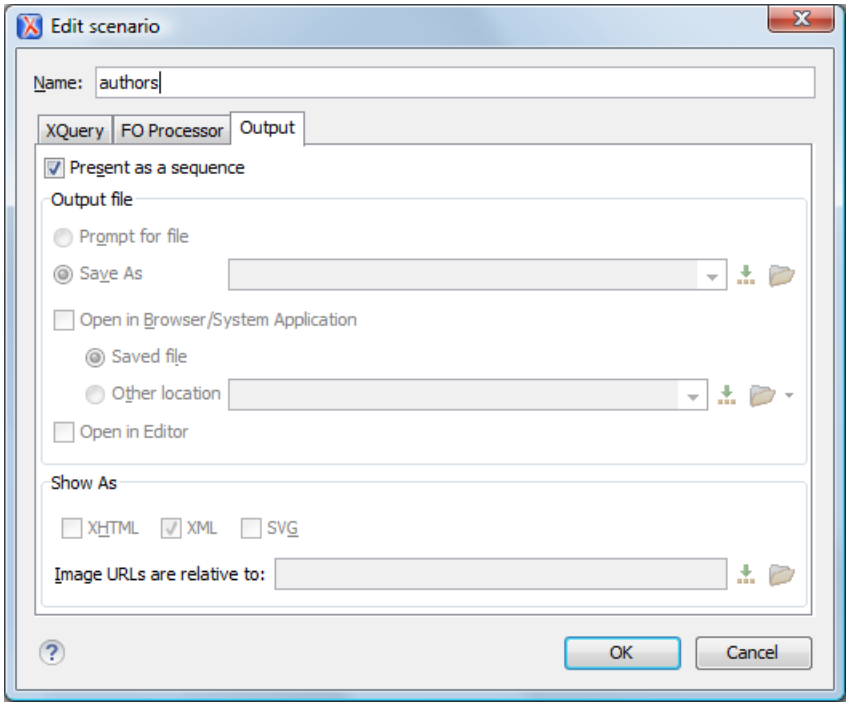

Figure 522: XQuery transformation result displayed in Sequence view

A chunk of the XQuery transformation result is displayed in the **Sequence** view.

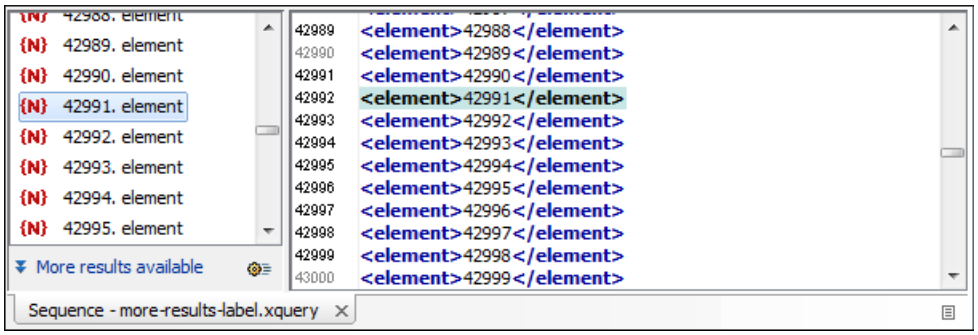

Figure 523: XQuery transformation result displayed in Sequence view

Advanced Saxon HE/PE/EE XQuery Transformation Options

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as

*those in the **Saxon HE/PE/EE** preferences page* but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the *global options* defined in the preferences page.

The advanced options for Saxon 9.7.0.19 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Recoverable errors ("-warnings")

Allows you to choose how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

Strip whitespaces ("-strip")

Allows you to choose how the *strip whitespaces* operation is handled. You can choose one of the following values:

- **All ("all")** - Strips *all* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document.
- **Ignore ("ignorable")** - Strips all *ignorable* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips *no* whitespace before further processing.

Optimization level ("-opt")

Allows you to set the optimization level. It is the value is an integer in the range of 0 (no optimization) to 10 (full optimization). This option allows optimization to be suppressed when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Use linked tree model ("-tree:linked")

This option activates the linked tree model.

XQuery version ("-qversion:(1.0|3.0|3.1)")

Allows you to select the XQuery version to be used by the Saxon XQuery processor for transformation and validation scenarios.

Initializer class

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the *net.sf.saxon.lib.Initializer* interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

The following advanced options are specific for Saxon 9.7.0.19 Professional Edition (PE) and Enterprise Edition (EE) only:

Use a configuration file ("-config")

Sets a Saxon 9.7.0.19 configuration file that is used for XQuery transformation and validation scenarios.

Allow calls on extension functions ("-ext")

If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

The advanced options that are specific for Saxon 9.7.0.19 Enterprise Edition (EE) are as follows:

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Generate bytecode ("--generateByteCode:(on|off)")

If you select this option, Saxon-EE attempts to generate Java bytecode for evaluation of parts of a query or stylesheet that are amenable to such an action. For further details regarding this option, go to *http://www.saxonica.com/documentation9.5/index.html#!javadoc*.

Enable XQuery update ("-update:(on|off)")

This option controls whether or not XQuery update syntax is accepted. The default value is off.

Backup files updated by XQuery ("-backup:(on|off)")

If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the **Enable XQuery update** option is selected.

Updating XML Documents using XQuery

Using the bundled Saxon 9.7.0.19 EE XQuery processor Oxygen XML Editor offers support for XQuery Update 1.0. The XQuery Update Facility provides expressions that can be used to make persistent changes to instances of the XQuery 1.0 and XPath 2.0 Data Model. Thus, besides querying XML documents, you can modify them using the various insert/delete/modify/create methods available in the *XQuery Update 1.0* standard.

Choose Saxon 9.7.0.19 EE as a transformer in the scenario associated with the XQuery files containing update statements and Oxygen XML Editor will notify you if the update was successful.

Example: Using XQuery Update to modify a tag name in an XML file

```
rename node doc("books.xml")//publisher[1]//book[1] as "firstBook"
```

Editing WSDL Documents

WSDL is an XML format for describing network services as a set of endpoints operating on messages containing either document-oriented or procedure-oriented information. The operations and messages are described abstractly, and then bound to a concrete network protocol and message format to define an endpoint. Related concrete endpoints are combined into abstract endpoints (services).

Oxygen XML Editor provides a special type of editor dedicated to WSDL documents. The WSDL editor offers support for validation, a specialized *Content Completion Assistant*, a component oriented ***Outline** view*, searching and refactoring operations, and support to generate documentation.

Both WSDL version 1.1 and 2.0 are supported and SOAP versions 1.1 and 1.2. That means that in the location where a SOAP extension can be inserted the *Content Completion Assistant* offers elements from both SOAP 1.1 and SOAP 1.2. Validation of SOAP requests is executed first against a SOAP 1.1 schema and then against a SOAP 1.2 schema. In addition to validation against the XSD schemas, Oxygen XML Editor also checks if the WSDL file conforms with the WSDL specification (available only for WSDL 1.1 and SOAP 1.1).

In the following example you can see how the errors are reported.

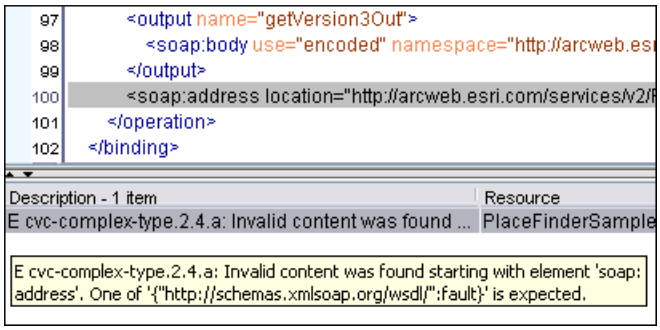

Figure 524: Validating a WSDL file

For more information about the WSDL editing support in Oxygen XML Editor, watch our video demonstration:

Related Information:
Editing XML Documents in Text Mode on page 492

Editing WSDL Documents in the Master Files Context

Smaller interrelated modules that define a complex WSDL structure cannot be correctly edited or validated individually, due to their interdependency with other modules. Oxygen XML Editor provides the support for defining the main module (or modules), allowing you to edit any of the imported/included files in the context of the larger WSDL structure.

You cat set a main WSDL document either using the *master files support from the **Project** view*, or using a validation scenario.

To set a *master file* using a validation scenario, add validation units that point to the main modules. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main WSDL document. In this case, it considers the current module as the main WSDL document.

The advantages of editing in the context of a *master file* include:

- Correct validation of a module in the context of a larger WSDL structure.
- *Content Completion Assistant* displays all components valid in the current context.
- The ***Outline** view* displays the components collected from the entire WSDL structure.

Note: When you edit an XML schema document that has a WSDL document set as master, the validation operation is performed over the master WSDL document.

For more information about editing WSDL documents in the *master files* context, watch our video demonstration:

Validating WSDL Documents

By default, WSDL files are validated as you type. To change this, *open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Editor** > **Document Checking**, and deselect the ***Enable automatic validation** option*.

To validate a WSDL document manually, select the **Validate** action from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Content Completion Assistance in WSDL Documents

The *Content Completion Assistant* is a powerful feature that enhances the editing of WSDL documents. It helps you define WSDL components by proposing context-sensitive element names. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

Another important capability of the *Content Completion Assistant* is to propose references to the defined components when you edit attribute values. For example, when you edit the `type` attribute of a `binding` element, the *Content Completion Assistant* proposes all the defined port types. Each proposal that the *Content Completion Assistant* offers is accompanied by a documentation hint.

Note: XML schema specific elements and attributes are offered when the current editing context is the internal XML schema of a WSDL document.

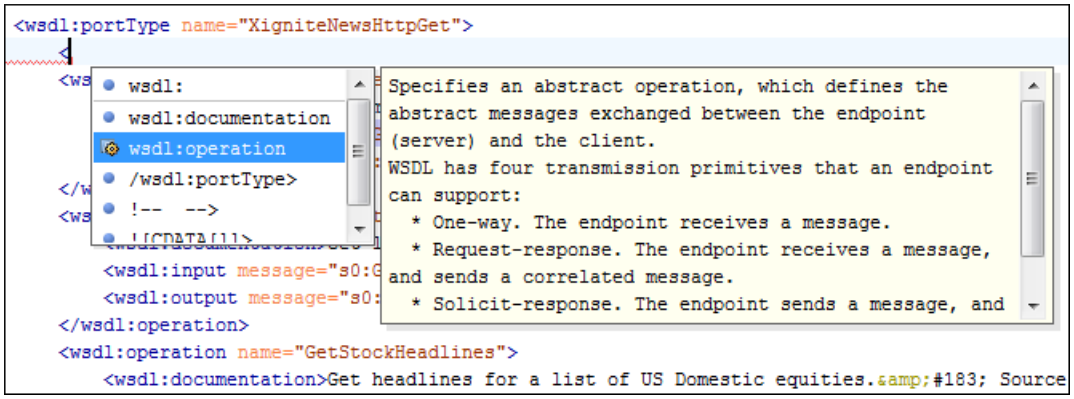

Figure 525: WSDL Content Completion Assistant

Note: If you are using the concept of *master files* to import/include modules, the *Content Completion Assistant* collects its components starting from the *master files*. The *master files* can be defined in the project or in the associated validation scenario. For more information about the *Master Files* support in Oxygen XML Editor, see *Defining Master Files at Project Level*.

Namespace prefixes in the scope of the current context are presented at the top of the content completion assistance window to speed up the insertion into the document of prefixed elements.

Figure 526: Namespace Prefixes in the Content Completion Assistant

For the common namespaces, such as XML Schema namespace (*http://www.w3.org/2001/XMLSchema*) or SOAP namespace (*http://schemas.xmlsoap.org/wsdl/soap/*), Oxygen XML Editor provides an easy mode to declare them by proposing a prefix for these namespaces.

WSDL Syntax Highlighting

Oxygen XML Editor supports syntax highlighting in WSDL documents to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for WSDL files, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XML** tab in the **Preview** pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the ***Editor > Syntax Highlight > Elements/ Attributes by Prefix*** *preferences page*.

Related Information:

Customize Syntax Highlight colors on page 105

WSDL Outline View

The **Outline** view for WSDL documents displays the list of all the components (services, bindings, port types and so on) of the currently open WSDL document along with the components of its imports.

If you use the ***Master Files** support*, the **Outline** view collects the components of a WSDL document starting from the *master files* of the current document.

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

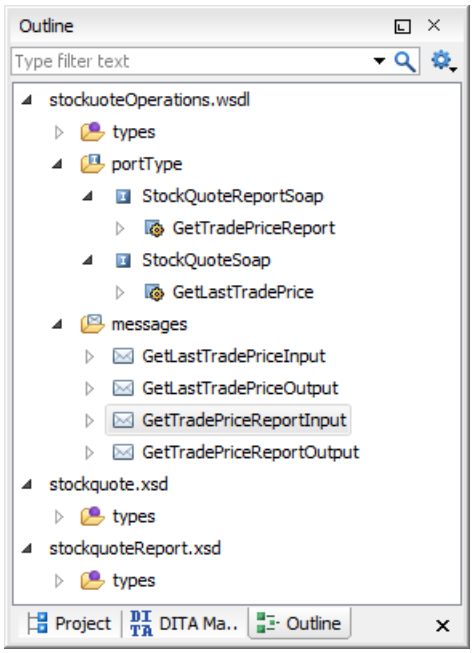

Figure 527: WSDL Outline View

The **Outline** view can display both the components of the current document and its XML structure, organized in a tree-like fashion. You can switch between the display modes by using the **Show XML structure** and **Show components** actions in the **Settings** menu on the **Outline** view toolbar. The following actions are available:

Filter returns exact matches

The text filter of the **Outline** view returns only exact matches.

Selection update on cursor move

Controls the synchronization between the **Outline** view and the current document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes in the WSDL editor. Selecting one of the components from the **Outline** view also selects the corresponding item in the current document.

When the **Show components** option is selected, the following actions are available:

Show XML structure

Displays the XML structure of the current document in a tree-like manner.

Sort

Sorts the components in the **Outline** view alphabetically.

Show all components

Displays all the components that were collected starting from current document or from the main document, if it is defined.

Show referable components
Displays all the components that you can reference from the current document.

Show only local components
Displays the components defined in the current file only.

Group by location
Groups the WSDL components by their location.

Group by type
Groups the WSDL components by their type.

Group by namespace
Groups the WSDL components by their namespace.

Note: By default, all the three grouping criteria are active.

When the **Show XML structure** option is selected, the following actions are available:

Show components
Switches the **Outline** view to the components display mode.

Flat presentation mode of the filtered results
When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions
Show/hide comments and processing instructions in the **Outline** view.

Show element name
Show/hide element name.

Show text
Show/hide additional text content for the displayed elements.

Show attributes
Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from *the Outline preferences panel*.

Configure displayed attributes
Displays the ***XML Structured Outline*** *preferences page*.

The following contextual menu actions are available in the **Outline** view when the **Show components** option is selected in the **Settings** menu:

Edit Attributes
Opens a dialog box that allows you to edit the attributes of the currently selected component.

Cut
Cuts the currently selected component.

Copy
Copies the currently selected component.

Delete
Deletes the currently selected component.

Search references
Searches for the references of the currently selected component.

Search references in
Searches for the references of the currently selected component in the context of a scope that you define.

Component dependencies

Opens the ***Component Dependencies*** *view* that displays the dependencies of the currently selected component.

Resource Hierarchy

Opens the ***Resource Hierarchy/Dependencies*** *view* that displays the hierarchy for the currently selected resource.

Resource Dependencies

Opens the ***Resource Hierarchy/Dependencies*** *view* that displays the dependencies of the currently selected resource.

Rename Component in

Renames the currently selected component in the context of a scope that you define.

The following contextual menu actions are available in the **Outline** view when the **Show XML structure** option is selected in the **Settings** menu:

Append Child

Displays a list of elements that you can insert as children of the current element.

Insert Before

Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After

Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes

Opens a dialog box that allows you to edit the attributes of the currently selected component.

Toggle Comment

Comments/uncomments the currently selected element.

Search references

Searches for the references of the currently selected component.

Search references in

Searches for the references of the currently selected component in the context of a scope that you define.

Component dependencies

Opens the ***Component Dependencies*** *view* that displays the dependencies of the currently selected component.

Rename Component in

Renames the currently selected component in the context of a scope that you define.

Cut

Cuts the currently selected component.

Copy

Copies the currently selected component.

Delete

Deletes the currently selected component.

Expand More

Expands the structure of a component in the **Outline** view.

Collapse All

Collapses the structure of all the component in the **Outline** view.

To switch from the tree structure to the text filter, use **Tab** and **Shift-Tab**.

Tip: The search filter is case insensitive. The following wildcards are accepted:

- ***** - any string
- **?** - any character
- **,** - patterns separator

If no wildcards are specified, the string to search is used as a partial match.

The content of the **Outline** view and the editing area are synchronized. When you select a component in the **Outline** view, its definition is highlighted in the editing area.

WSDL Resource Hierarchy/Dependencies View in WSDL Documents

The **Resource Hierarchy/Dependencies** view allows you to see the hierarchy/dependencies for a WSDL resource. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Note: The hierarchy of a WSDL resource includes the hierarchy of imported XML Schema resources. The dependencies of an XML Schema resource present the WSDL documents that import the schema.

To view the hierarchy of a WSDL document, select the document in the ***Project*** *view* and choose **Resource Hierarchy** from the contextual menu.

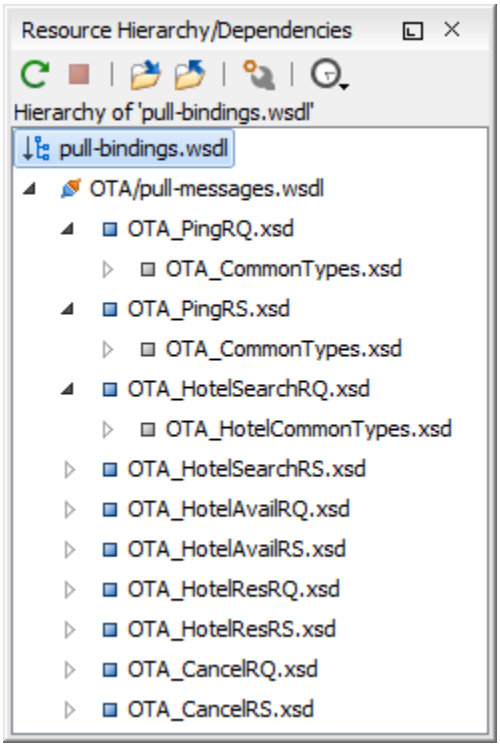

Figure 528: Resource Hierarchy/Dependencies View

If you want to see the dependencies of a WSDL document, select the document in the ***Project*** *view* and choose **Resource Dependencies** from the contextual menu.

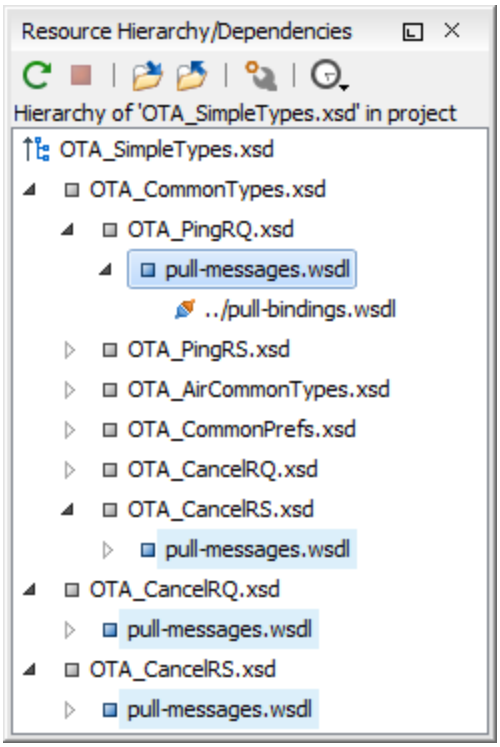

Figure 529: Resource Hierarchy/Dependencies View

The following actions are available in the **Resource Hierarchy/Dependencies** view:

Refresh

Refreshes the Hierarchy/Dependencies structure.

Stop

Stops the hierarchy/dependencies computing.

Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

Renames the selected resource.

Show Resource Hierarchy

Shows the hierarchy for the selected resource.

Show Resource Dependencies

Shows the dependencies for the selected resource.

 **Add to Master Files**

Adds the currently selected resource in *the **Master Files** directory*.

Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon .

Note: The **Move resource** or **Rename resource** actions give you the option to *update the references to the resource*.

Related Information:

Search and Refactor Operations Scope on page 691

Moving/Renaming WSDL Resources

You can move and rename a resource presented in the **Resource/Hierarchy Dependencies** view, using the **Rename resource** and **Move resource** refactoring actions from the contextual menu.

When you select the **Rename** action in the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Rename resource** dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references** - Select this option to update the references to the resource you are renaming.

When you select the **Move** action from the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Move resource** dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name.

If the **Update references of the moved resource(s)** option is selected, a **Preview** option (which opens the **Preview** dialog box) is available for both actions. The **Preview** dialog box presents a list with the resources that are updated.

WSDL Component Dependencies View

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

To see the dependencies of a WSDL component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

This action is available for all WSDL components (`messages`, `port types`, `operations`, `bindings`, and so on).

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon .

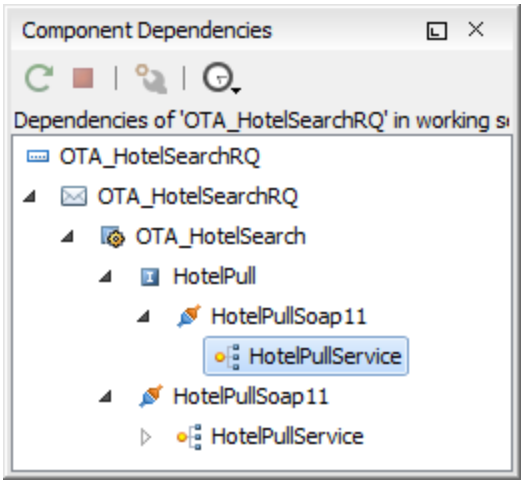

Figure 530: Component Dependencies View

The **Component Dependencies** view includes the following toolbar actions:

Refresh

Refreshes the dependencies structure.

Stop

Stops the dependency computation.

Configure

Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

Go to First Reference

Selects the first reference of the currently selected component in the dependencies tree.

Go to Component

Shows the definition of the currently selected component in the dependencies tree.

Related Information:

Searching and Refactoring Operations Scope in WSDL Documents on page 855

Highlight Component Occurrences in WSDL Documents

When you position your mouse cursor over a component in a WSDL document, Oxygen XML Editor searches for the component declaration and all its references and highlights them automatically.

Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected.

To change the default behavior of **Highlight Component Occurrences**, *open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Editor** > **Mark Occurrences**. You can also trigger a search using the **Search** > **Search Occurrences in File ()** action from contextual menu. Matches are displayed in separate tabs of the ***Results*** *view*.

Searching and Refactoring Operations in WSDL Documents

Search Actions

The following search actions are available from the **Search** submenu in the contextual menu of the current editor or from the **Document** > **References** menu:

- **Search References** - Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.
- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.
- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the **Document** > **Schema** menu:

- **Go to Definition** - Takes you to the location of the definition of the current item.

  Note: You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

Refactoring Actions

The following refactoring actions are available from the **Refactoring** submenu from the **Document** > **Refactoring** menu or in the contextual menu of the current editor:

- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.
- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

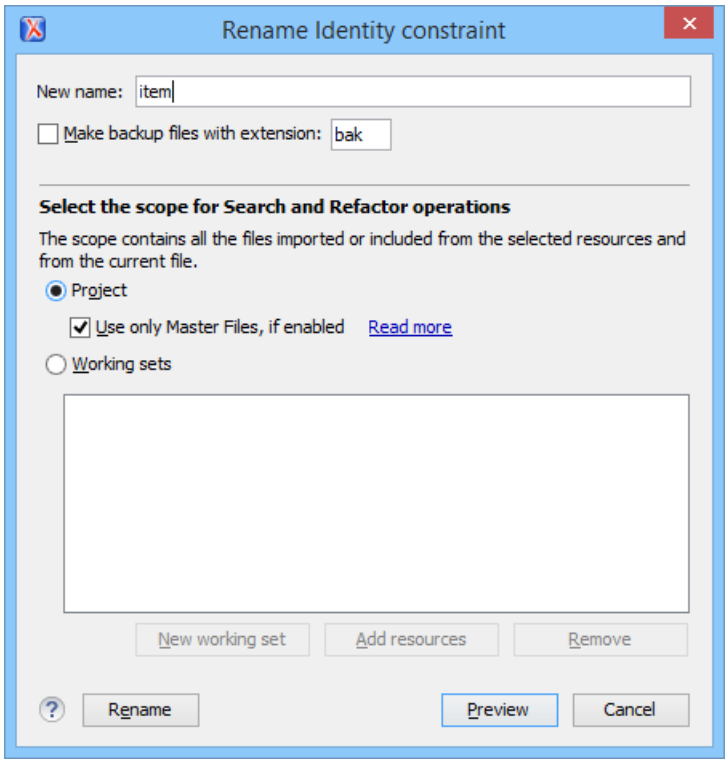

Figure 531: Rename Identity Constraint Dialog Box

Searching and Refactoring Operations Scope in WSDL Documents

The *scope* is a collection of documents that define the context of a search and refactor operation. To control it you can use the **Change scope** operation, available in the *Quick Assist* action set or on the **Resource Hierarchy/Dependency View** toolbar. You can restrict the scope to the current project or to one or multiple *working sets*. The **Use only Master Files, if enabled** checkbox allows you to restrict the scope of the search and refactor operations to the resources from the **Master Files** directory. Click **read more** for details about the *Master Files support*.

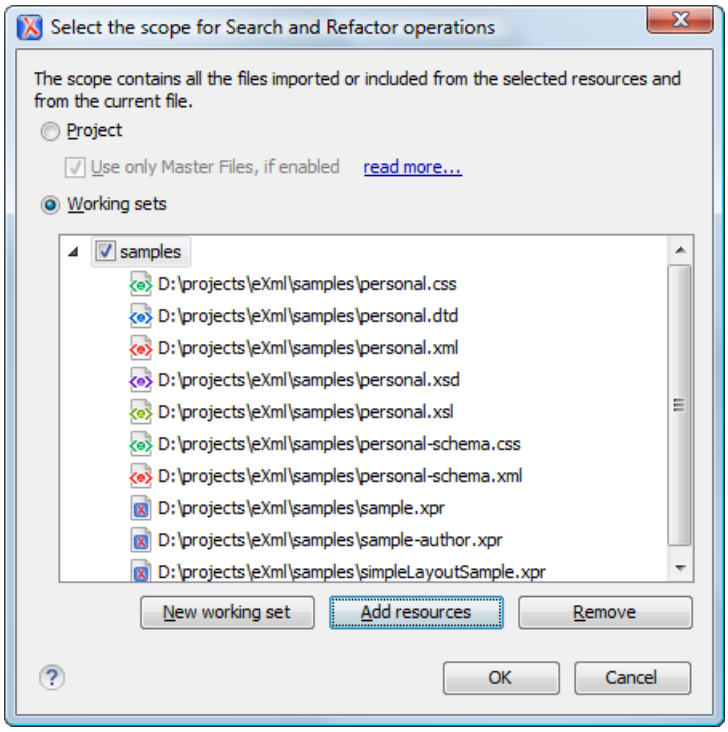

Figure 532: Change Scope Dialog Box

The scope you define is applied to all future search and refactor operations until you modify it. Contextual menu actions allow you to add or delete files, folders, and other resources to the *working set* structure.

Quick Assist Support in WSDL Documents

The *Quick Assist feature* is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon ( ) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the *quick assist* menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

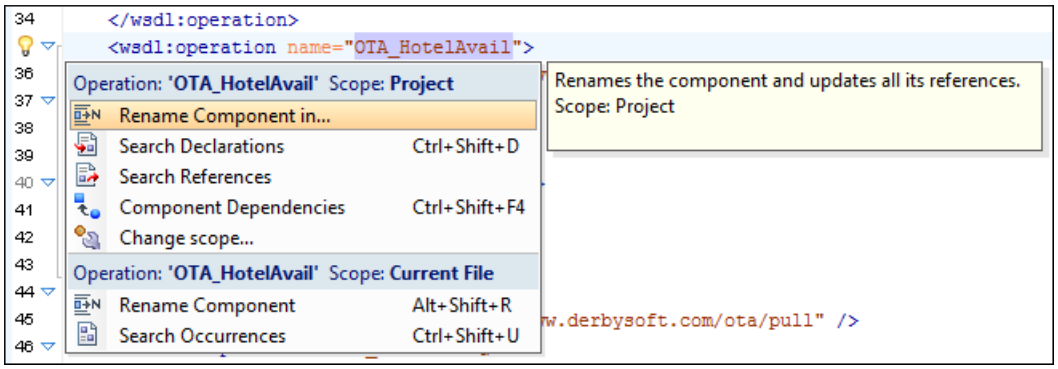

Figure 533: WSDL Quick Assist Support

The *Quick Assist* support offers direct access to the following actions:

Rename Component in

Renames the component and all its dependencies.

Search Declarations

Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

Search References

Searches all references of the component in a predefined scope.

Component Dependencies

Searches the component dependencies in a predefined scope.

Change Scope

Configures the scope that will be used for future search or refactor operations.

Rename Component

Allows you to rename the current component in-place.

Search Occurrences

Searches all occurrences of the component within the current file.

Generating Documentation for WSDL Documents

You can use Oxygen XML Editor to generate detailed documentation for the components of a WSDL document in HTML format. You can select the WSDL components to include in your output and the level of details to present for each of them. Also, the components are hyperlinked. You can also generate the documentation in a *custom output format* by using a custom stylesheet.

Note: The WSDL documentation includes the XML Schema components that belong to the internal or imported XML schemas.

To generate documentation for a WSDL document, select **WSDL Documentation** from the **Tools** > **Generate Documentation** menu or from the **Generate Documentation** submenu in the contextual menu of the ***Project*** *view*.

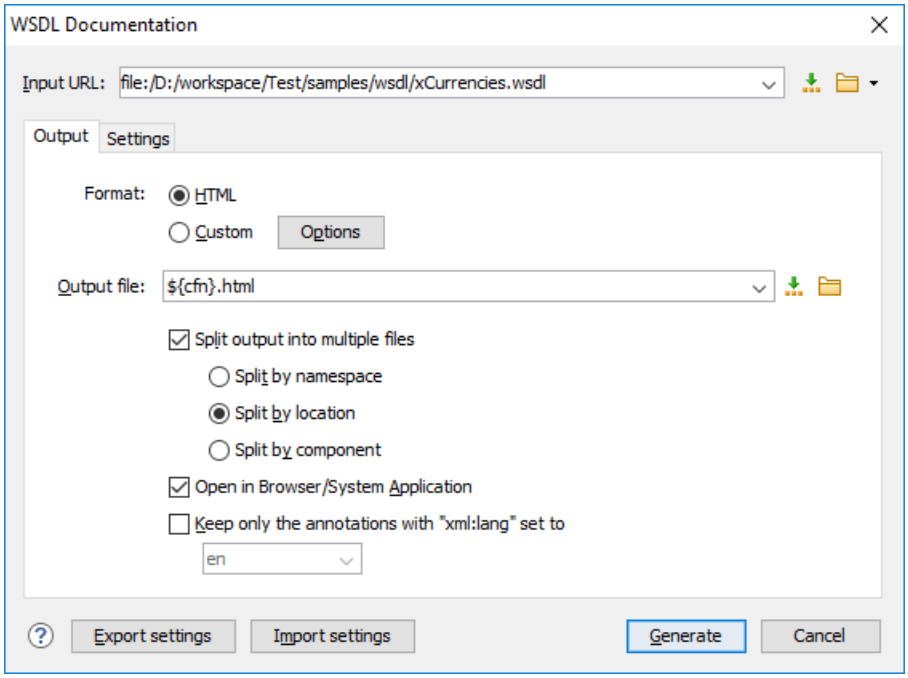

Figure 534: WSDL Documentation Dialog Box

The **Input URL** field of the dialog box must contain the full path to the WSDL document that you want to generate documentation for. The WSDL document may be a local or a remote file. You can specify the path to the WSDL file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.

Output Tab

The following options are available in the **Output** tab:

- **Format** - Allows you to choose between the following formats:
  - **HTML** - The documentation is generated in *HTML output format*.

- **Custom** - The documentation is generated in a *custom output format*, allowing you to control the output. Click the **Options** button to open a **Custom format options** dialog box where you can specify a custom stylesheet for creating the output. There is also an option to **Copy additional resources to the output folder** and you can select the path to the additional **Resources** that you want to copy. You can also choose to keep the intermediate XML files created during the documentation process by deselecting the **Delete intermediate XML file** option.

- **Output file** - You can specify the path of the output file by entering it in the text field, or by using the **Insert Editor Variables** button or the options in the **Browse** drop-down menu.
- **Split output into multiple files** - Instructs the application to split the output into multiple files. For large WSDL documents, choosing a different split criterion may generate smaller output files providing a faster documentation browsing. You can choose to split them by namespace, location, or component name.
- **Open in Browser/System Application** - Opens the result in the system application associated with the output file type.

  Note: To set the browser or system application that will be used, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.
- **Keep only the annotations with xml:lang set to** - The generated output will contain only the annotations with the `xml:lang` attribute set to the selected language. If you choose a primary language code (for example, **en** for English), this includes all its possible variations (**en-us**, **en-uk**, etc.).

Setting Tab

When you generate documentation for a WSDL document, you can choose what components to include in the output and the details to be included in the documentation.

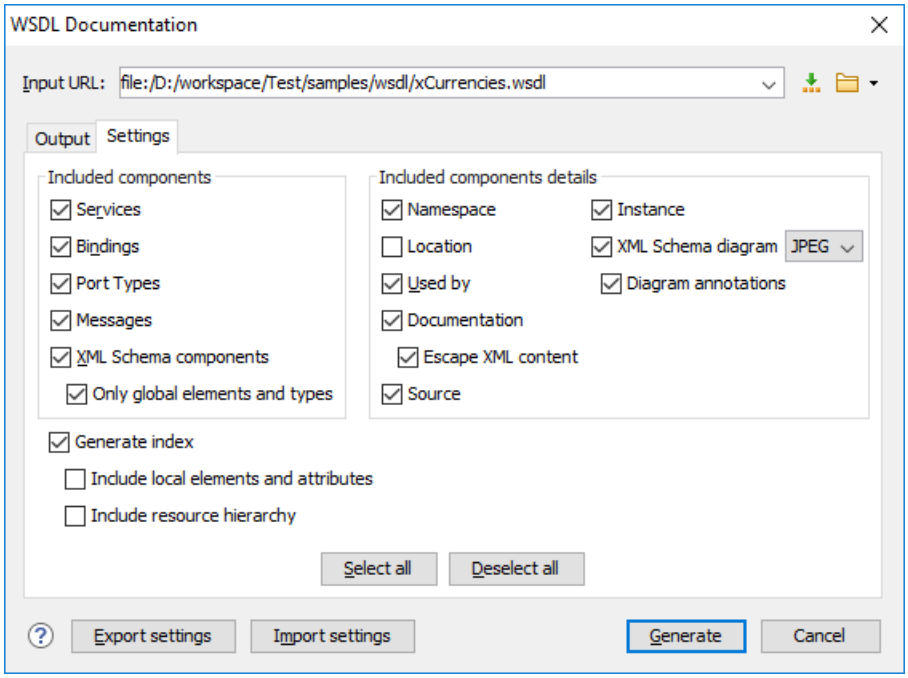

Figure 535: Settings Tab of the WSDL Documentation Dialog Box

The **Settings** tab allows you to choose whether or not to include the following:

- **Components**
  - **Services** - Specifies whether or not the generated documentation includes the WSDL services.
  - **Bindings** - Specifies whether or not the generated documentation includes the WSDL bindings.
  - **Port Types** - Specifies whether or not the generated documentation includes the WSDL port types.
  - **Messages** - Specifies whether or not the generated documentation includes the WSDL messages.

- **XML Schema Components** - Specifies whether or not the generated documentation includes the XML Schema components.
  - **Only global elements and types** - Specifies whether or not the generated documentation includes only global elements and types.
- **Component Details**
  - **Namespace** - Presents the namespace information for WSDL or XML Schema components.
  - **Location** - Presents the location information for each WSDL or XML Schema component.
  - **Used by** - Presents the list of components that reference the current one.
  - **Documentation** - Presents the component documentation. If you choose **Escape XML Content**, the XML tags are presented in the documentation.
  - **Source** - Presents the XML fragment that defines the current component.
  - **Instance** - Generates a sample XML instance for the current component.

    Note: This option applies to the XML Schema components only.
  - **XML Schema Diagram** - Displays the diagram for each XML Schema component. You can choose the image format (JPEG, PNG, GIF, SVG) to use for the diagram section.
    - **Diagram annotations** - Specifies whether or not the annotations of the components presented in the diagram sections are included.
- **Generate index** - Displays an index with the components included in the documentation.
  - **Include local elements and attributes** - If selected, local elements and attributes are included in the documentation index.
  - **Include resource hierarchy** - Specifies whether or not the resource hierarchy for an XML Schema documentation is generated. It is deselected by default.

Export settings - Save the current settings in a settings file for further use (for example, with the exported settings file you can generate the same *documentation from the command-line interface*.)

Import settings - Reloads the settings from the exported file.

Generate - Use this button to generate the WSDL documentation.

Generating WSDL Documentation in HTML Format

The WSDL documentation generated in HTML format is presented in a visual diagram style with various sections, hyperlinks, and options.

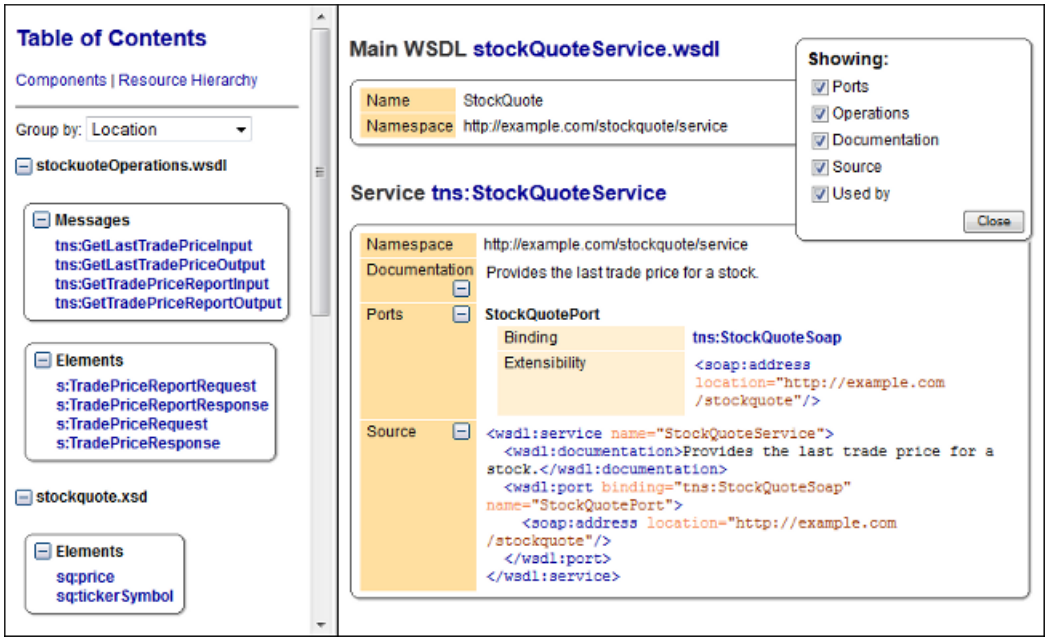

Figure 536: WSDL Documentation in HTML Format

The documentation of each component is presented in a separate section. The title of the section is composed of the component type and the component name. The component information (namespace, documentation, etc.) is presented in a tabular form.

If you choose to split the output into multiple files, the table of contents is displayed in the left frame and is divided in two tabs: **Components** and **Resource Hierarchy**.

The **Components** tab allows you to group the contents by namespace, location, or component type. The WSDL components from each group are sorted alphabetically. The **Resource Hierarchy** tab displays the dependencies between WSDL and XML Schema modules in a tree-like fashion. The root of the tree is the WSDL document that you generate documentation for.

After the documentation is generated, you can collapse or expand details for some WSDL components by using the **Showing** options or the **Collapse** or **Expand** buttons.

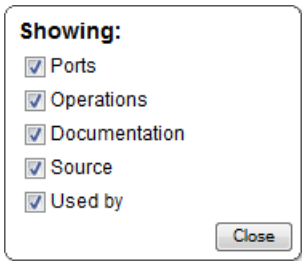

Figure 537: Showing Options

Generating WSDL Documentation in a Custom Format

To obtain the default HTML documentation output from a WSDL document, Oxygen XML Editor uses an intermediary XML document to which it applies an XSLT stylesheet. To create a custom output from your WSDL document, edit the `wsdlDocHtml.xsl` XSLT stylesheet or create your own.

Note: The `wsdlDocHtml.xsl` stylesheet that is used to obtain the HTML documentation is located in the *`[OXYGEN_INSTALL_DIR]`*`/frameworks/wsdl_documentation/xsl` folder.

Note: The intermediary XML document complies with the `wsdlDocSchema.xsd` XML Schema. This schema is located in the *`[OXYGEN_INSTALL_DIR]`*`/frameworks/wsdl_documentation` folder.

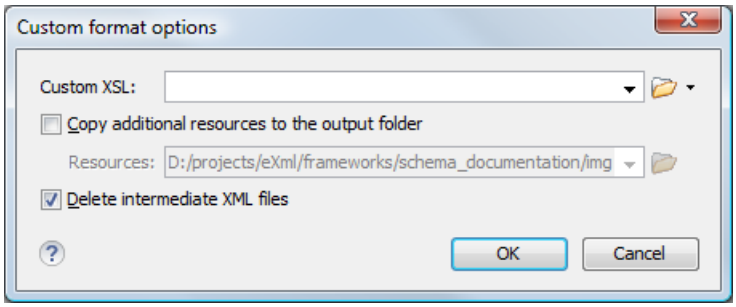

Figure 538: Custom Format Options Dialog Box

When using a custom format, you can also copy additional resources into the output folder or choose to keep the intermediate XML files created during the documentation process.

Generating WSDL Documentation from the Command-Line Interface

To generate documentation for a WSDL document from the command line, open the **WSDL Documentation** dialog box and click **Export settings**. Using the exported settings file you can generate the same documentation from the command line by running the following scripts:

- `wsdlDocumentation.bat` on Windows.
- `wsdlDocumentation.sh` on Mac OS X and Linux.

The scripts are located in the installation folder of Oxygen XML Editor. You can integrate the scripts in an external batch process launched from the command-line interface.

WSDL SOAP Analyzer

WSDL SOAP Analyzer is a tool that helps you test if the messages defined in a Web Service Descriptor (WSDL) are accepted by a Web Services server.

After you edit and validate your Web service descriptor against a mix of the XML Schemas for WSDL and SOAP, it is easy to check if the defined SOAP messages are accepted by the remote Web Services server by using the integrated **WSDL SOAP Analyzer** tool (available from the toolbar or **Tools** menu).

Oxygen XML Editor provides two ways of testing, one for the currently edited WSDL document and another for the remote WSDL documents that are published on a web server. To open the **WSDL SOAP Analyzer** tool for the currently edited WSDL document do one of the following:

- Click the **WSDL SOAP Analyzer** toolbar button.
- Use the **WSDL SOAP Analyzer** action from the **Tools** menu.
- Go to **Open with** > **WSDL SOAP Analyzer** in the contextual menu of the ***Project*** view.

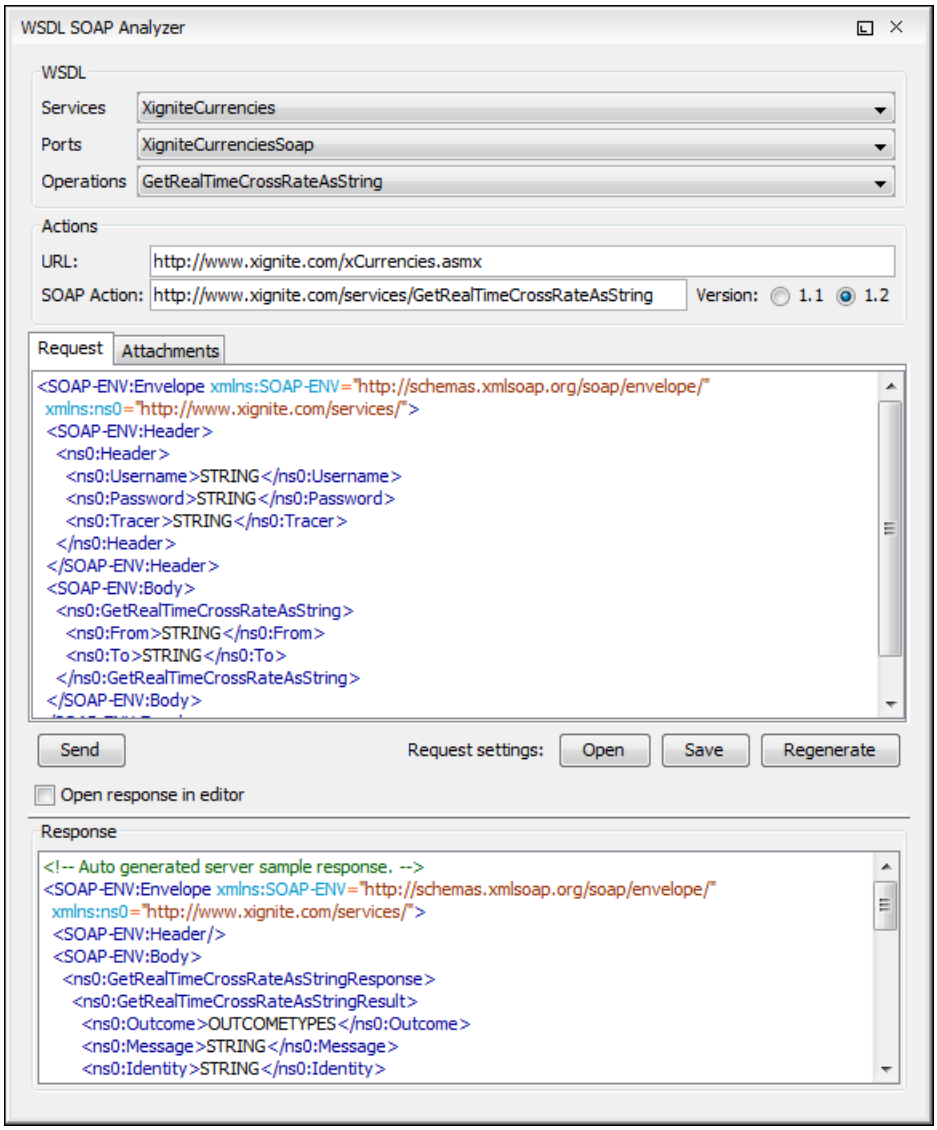

Figure 539: WSDL SOAP Analyzer Dialog Box

This tool contains a SOAP analyzer and sender for Web Services Description Language file types. The analyzer fields are as follows:

- **Services** - The list of services defined by the WSDL file.
- **Ports** - The ports for the selected service.

- **Operations** - The list of available operations for the selected service.
- **Action URL** - The script that serves the operation.
- **SOAP Action** - Identifies the action performed by the script.
- **Version** - Choose between 1.1 and 1.2. The SOAP version is selected automatically depending on the selected port.
- **Request Editor** - It allows you to compose the web service request. When an action is selected, Oxygen XML Editor tries to generate as much content as possible for the SOAP request. The envelope of the SOAP request has the correct namespace for the selected SOAP version, that is *http://schemas.xmlsoap.org/soap/envelope/* for SOAP 1.1 or *http://www.w3.org/2003/05/soap-envelope* for SOAP 1.2. Usually you just have to change a few values for the request to be valid. The *Content Completion Assistant* is available for this editor and is driven by the schema that defines the type of the current message. While selecting various operations, Oxygen XML Editor remembers the modified request for each one. You can press the **Regenerate** button to overwrite your modifications for the current request with the initial generated content.
- **Attachments List** - You can define a list of file URLs to be attached to the request.
- **Response Area** - Initially it displays an auto generated server sample response so you can have an idea about how the response looks like. After pressing the **Send** button, it presents the message received from the server in response to the Web Service request. It may show also error messages. If the response message contains attachments, Oxygen XML Editor prompts you to save them, then tries to open them with the associated system application.
- **Errors List** - There may be situations where the WSDL file is respecting the WSDL XML Schema, but it fails to be valid (for example, in the case of a message that is defined by means of an element that is not found in the types section of the WSDL). In such a case, the errors are listed here. This list is presented only when there are errors.
- **Send Button** - Executes the request. A status dialog box is displayed when Oxygen XML Editor is connecting to the server.

The testing of a WSDL file is straight-forward: click the WSDL analysis button, then select the service, the port, and the operation. The editor generates the skeleton for the SOAP request. You can edit the request, eventually attach files to it and send it to the server. Watch the server response in the response area. You can find more details in the *Testing Remote WSDL Files* section.

Note: SOAP requests and responses are automatically validated in the **WSDL SOAP Analyzer** using the XML Schemas specified in the WSDL file.

Once defined, a request derived from a Web Service descriptor can be saved with the **Save** button to a Web Service SOAP Call (WSSC) file for later reuse. In this way, you save time in configuring the URLs and parameters.

You can open the result of a Web Service call in an editor panel using the **Open** button.

Testing Remote WSDL Files

To open and test a remote WSDL file the steps are the following:

1. Go to **Tools** > **WSDL SOAP Analyzer** .
2. On the **WSDL File** tab enter the URL of the remote WSDL file.
   You enter the URL:
   - by typing
   - by browsing the local file system
   - by browsing a remote file system
   - by browsing *a UDDI Registry*
3. Press the **OK** button.
   This will open the ***WSDL SOAP Analyzer** tool*. In the **Saved SOAP Request** tab you can open directly a previously saved Web Service SOAP Call (WSSC) file, thus skipping the analysis phase.

UDDI Registry Browser

Pressing the button in the **WSDL File Opener** dialog box (menu **Tools** > **WSDL SOAP Analyzer**) opens the **UDDI Registry Browser** dialog box.

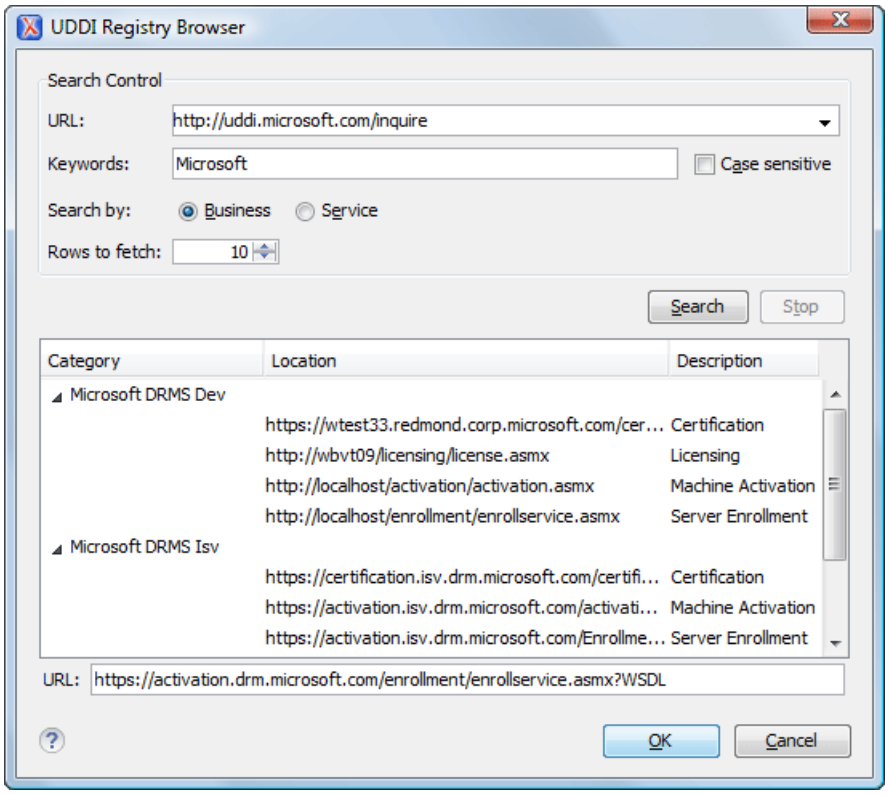

Figure 540: UDDI Registry Browser Dialog Box

The fields of the dialog box are as follows:

- **URL** - Type the URL of an UDDI registry or choose one from the default list.
- **Keywords** - Enter the string you want to be used when searching the selected UDDI registry for available Web services.
- **Rows to fetch** - The maximum number of rows to be displayed in the result list.
- **Search by** - You can choose to search either by company or by provided service.
- **Case sensitive** - When selected, the search takes into account the keyword case.
- **Search** - The WSDL files that matched the search criteria are added in the result list.

When you select a WSDL from the list and click the **OK** button, the **UDDI Registry Browser** dialog box is closed and you are returned to the **WSDL File Opener** dialog box.

Editing CSS Stylesheets

Oxygen XML Editor includes a built-in editor for CSS stylesheets. This section presents the features of the CSS editor and how these features should be used. The features of the CSS editor include:

- **Create new CSS files and templates** - You can use the built-in new file wizards to *create new CSS documents or templates*.
- **Open and Edit CSS files** - CSS files can be opened and edited in a source editing mode.
- **Validation** - Presents validation errors in CSS files.
- **Content completion** - Offers proposals for properties and the values that are available for each property.
- **Syntax highlighting** - The syntax highlighting in Oxygen XML Editor makes CSS files more readable.
- **Shortcut to open resources** - You can use **Ctrl + Single-Click (Command + Single-Click on OS X)** to open imported stylesheets or other resources (such as images) in the default system application for the particular type of resource.

Validating CSS Stylesheets

Oxygen XML Editor includes a built-in *CSS Validator*, integrated with general validation support. This makes the *usual validation features* for presenting errors also available for CSS stylesheets.

When you edit a CSS document, you can access the *CSS validator options* by selecting **Validation options** from the **Document** > **Validate** menu.

The CSS properties accepted by the validator are those included in the current CSS profile that is selected in *the CSS validation preferences*. The **CSS 3 with Oxygen extensions** profile includes all the CSS 3 standard properties plus the *CSS extensions specific for Oxygen* that can be used in *Author mode*. That means all Oxygen specific extensions are accepted in a CSS stylesheet by *the built-in CSS validator* when this profile is selected.

Specify Custom CSS Properties

To specify custom CSS properties, follow these steps:

1. Create a file named `CustomProperties.xml` that has the following structure:

```
<?xml version="1.0" encoding="UTF-8"?>
<css_keywords
      xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
      xsi:schemaLocation="http://www.oxygenxml.com/ns/css
 http://www.oxygenxml.com/ns/css/CssProperties.xsd"
      xmlns="http://www.oxygenxml.com/ns/css">
      <property name="custom">
      <summary>Description for custom property.</summary>
        <value name="customValue"/>
        <value name="anotherCustomValue"/>
      </property>
</css_keywords>
```

2. Go to your desktop and create the `builtin/css-validator/` folder structure.
3. Press and hold **Shift** and right-click anywhere on your desktop. From the contextual menu, select **Open Command Window Here**.
4. In the command line, run the `jar cvf custom_props.jar builtin/` command.
   The `custom_props.jar` file is created.
5. Go to *`[OXYGEN_INSTALL_DIR]`*`/lib` and create the `endorsed` folder. Copy the `custom_props.jar` file to *`[OXYGEN_INSTALL_DIR]`*`/lib/endorsed`.

Content Completion in CSS Stylesheets

A *Content Completion Assistant*, similar to *the one available for XML documents* offers the CSS properties and the values available for each property. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut and is context-sensitive when invoked for the value of a property. The *Content Completion Assistant* also includes *code templates that can be used to quickly insert code fragments* into CSS stylesheets. The code templates that are proposed include form controls, actions, and **Author** mode operations.

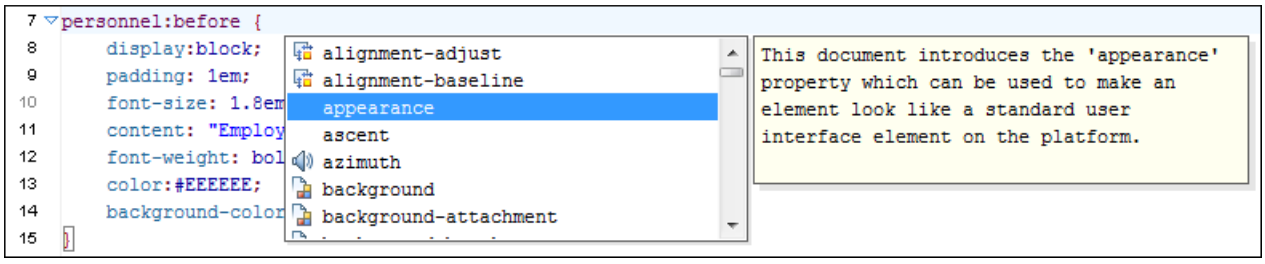

Figure 541: Content Completion in CSS Stylesheets

The properties and values available are dependent on the CSS Profile selected in the ***CSS*** *preferences*. The CSS 2.1 set of properties and property values is used for most of the profiles. However, with CSS 1 and CSS 3 specific proposal sets are used.

The profile *CSS 3 with Oxygen extensions* includes all the CSS 3 standard properties plus the *CSS extensions specific for Oxygen XML Editor* that can be used in ***Author*** *mode*.

Proposals for CSS Selectors - After inserting a *CSS selector*, the content completion assistance will propose a list of pseudo-elements and pseudo-classes that are available for the selected CSS profile.

Proposals for `@media` and `@import` Rules - After inserting `@media` or `@import <url>` rules, the content completion assistance will propose a list of supported media types.

Related Information:

Specify Custom CSS Properties on page 864

Syntax Highlighting in CSS Files

Oxygen XML Editor supports syntax highlighting in CSS files to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for CSS files, follow these steps:

1. *Open the **Preferences** dialog box **(Options** > **Preferences)***.
2. Go to ***Editor*** > ***Syntax Highlight***.
3. Select and expand the **CSS** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Related Information:

Syntax Highlight Preferences on page 105

CSS Outline View

The **Outline** view for CSS stylesheets presents the import declarations for other CSS stylesheet files and all the selectors defined in the current CSS document. The selector entries can be presented as follows:

- In the order they appear in the document.
- Sorted by the element name used in the selector.
- Sorted by the entire selector string representation.

You can synchronize the selection in the **Outline** view with the cursor moves or changes you make in the stylesheet document. When you select an entry from the **Outline** view, Oxygen XML Editor highlights the corresponding import or selector in the CSS editor.

By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

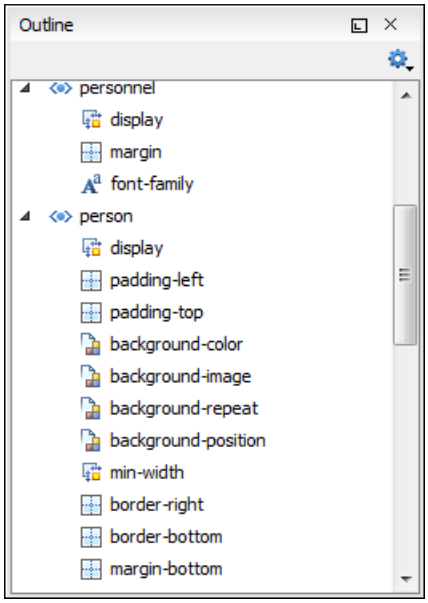

Figure 542: CSS Outline View

The selectors presented in this view can be found quickly using the key search field. When you press a sequence of character keys while the focus is in the view, the first selector that starts with that sequence is selected automatically.

Folding in CSS Stylesheets

In a large CSS stylesheet document, some styles can be collapsed so that only the styles that are needed remain in focus. The same *folding features available for XML documents* are also available in CSS stylesheets.

Note: To enhance your editing experience, you can select entire blocks (parts of text delimited by brackets) by double-clicking somewhere inside the brackets.

Formatting and Indenting CSS Stylesheets (Pretty Print)

If the edited CSS stylesheet becomes unreadable because of the bad alignment of the text lines, the *format and indent operation available for XML documents* is also available for CSS stylesheets. It works in the same way as for XML documents and is available as the same menu and toolbar action.

Minifying CSS Stylesheets

Minification (or *compression*) of a CSS document is the practice of removing unnecessary code without affecting the functionality of the stylesheet.

To minify a CSS, invoke the contextual menu anywhere in the edited document and choose the **Minify CSS** action. Oxygen XML Editor opens a dialog box that allows you to:

- Set the location of the resulting CSS.
- Place each style rule on a new line.

After pressing **OK**, Oxygen XML Editor performs the following actions:

- All spaces are normalized (all leading and trailing spaces are removed, while sequences of white spaces are replaced with single space characters).
- All comments are removed.

Note: The CSS minifier relies heavily upon the W3C CSS specification. If the content of the CSS file you are trying to minify does not conform with the specifications, an error dialog box will be displayed, listing all errors encountered during the processing.

The resulting CSS stylesheet gains a lot in terms of execution performance, but loses in terms of readability. The source CSS document is left unaffected.

Note: To restore the readability of a minified CSS, invoke the **Format and Indent** action from the **Document** > **Source** menu, the **Source** submenu from the contextual menu, or **Source** toolbar. However, this action will not recover any of the deleted comments.

Editing LESS Stylesheets

Oxygen XML Editor provides support for stylesheets coded with the LESS dynamic stylesheet language. LESS extends the CSS language by adding features that allow mechanisms such as *variables*, *nesting*, *mixins*, *operators*, and *functions*. Oxygen XML Editor offers additional LESS features that include:

- **Create new LESS files and templates** - You can use the built-in new file wizards to *create new LESS documents or templates*.
- **Open and Edit LESS files** - LESS files can be opened and edited in a source editing mode.
- **Validation** - Presents validation errors in LESS files.
- **Content completion** - Offers proposals for properties and the values that are available for each property.
- **Compile to CSS** - Options are available to compile LESS files to CSS.
- **Syntax highlighting** - Oxygen XML Editor supports syntax highlighting in LESS files, although there may be some limitations in supporting all the LESS constructs.

- **Shortcut to open resources** - While editing LESS files, you can use **Ctrl + Single-Click (Command + Single-Click on OS X)** to open imported stylesheets or other resources (such as images) in the default system application for the particular type of resource.

For more information about LESS go to *http://lesscss.org/*.

Validating LESS Stylesheets

Oxygen XML Editor includes a built-in *LESS CSS Validator*, integrated with general validation support. The *usual validation features* for presenting errors also available for LESS stylesheets.

Oxygen XML Editor provides three validation methods:

- Automatic validation as you type - marks validation errors in the document as you are editing.
- Validation upon request, by pressing the **Validate** button from the **Validation** toolbar drop-down menu. An error list is presented in the message panel at the bottom of the editor.
- Validation scenarios, by selecting **Configure Validation Scenario(s)** from the **Validation** toolbar drop-down menu. Errors are presented in the message panel at the bottom of the editor. This is useful when you need to validate the current file as part of a larger LESS import hierarchy (for instance, you may change the URL of the file to validate to the root of the hierarchy).

Content Completion in LESS Stylesheets

A *Content Completion Assistant* offers the LESS properties and the values available for each property. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut and is context-sensitive when invoked for the value of a property in a LESS file. The *Content Completion Assistant* also includes *code templates that can be used to quickly insert code fragments* into LESS stylesheets. The code templates that are proposed include form controls, actions, and **Author** mode operations.

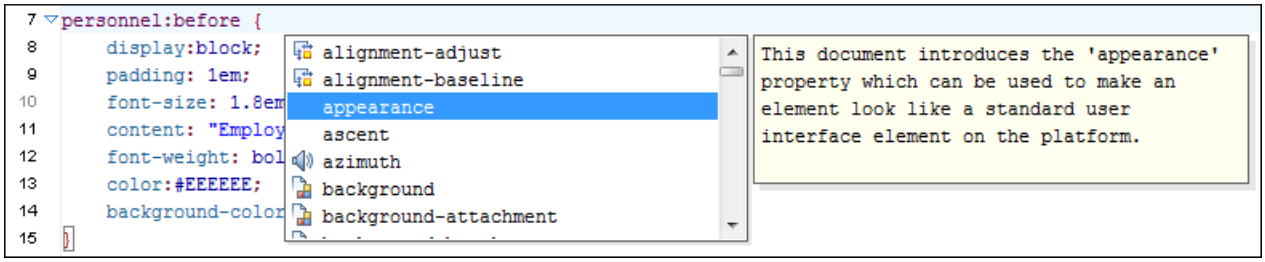

Figure 543: Content Completion in LESS Stylesheets

The properties and values available are dependent on the CSS Profile selected in the *CSS preferences* .

Syntax Highlighting in LESS Files

Oxygen XML Editor supports syntax highlighting in LESS files to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for LESS files, follow these steps:

1. *Open the **Preferences** dialog box (**Options** > **Preferences**)*.
2. Go to ***Editor** > **Syntax Highlight***.
3. Select and expand the **LESS** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Syntax Highlight Preferences on page 105

Compiling LESS Stylesheets to CSS

When editing LESS files, you can compile the files into CSS. Oxygen XML Editor provides both manual and automatic options to compile LESS stylesheets into CSS.

Important: The LESS processor works well only with files having the *UTF-8* encoding. Thus, it is highly recommended that you always use the `utf-8` encoding when working with LESS files or the files they import (other LESS or CSS files). You can use the following directive at the beginning of your files:

```
@charset "utf-8";
```

You have two options for compiling LESS files to CSS:

1. Use the contextual menu in a LESS file and select **Compile to CSS (Ctrl + Shift + C (Command + Shift + C on OS X))**.
2. Select the ***Automatically compile LESS to CSS when saving*** *option* in the settings (*open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to **Editor** > **Open/Save** > **Save Hooks**). If selected, when you save a LESS file it will automatically be compiled to CSS (this option is deselected by default).

   Important: If this option is selected, when you save a LESS file, the CSS file that has the same name as the LESS file is overwritten without warning. Make sure all your changes are made in the LESS file. Do not edit the CSS file directly, as your changes might be lost.

Editing Relax NG Schemas

An XML Schema describes the structure of an XML document and is used to validate XML document instances against it, to check that the XML instances conform to the specified requirements. If an XML instance conforms to the schema then it is said to be valid. Otherwise, it is invalid.

Oxygen XML Editor offers support for editing Relax NG schema files in the following editing modes:

- ***Text editing mode*** - Allows you to edit Relax NG schema files in a source editing mode, along with a schema design pane with two tabs that offer a ***Full Model View*** and ***Logical Model View***.
- ***Grid editing mode*** - Displays Relax NG schema files in a structured spreadsheet-like grid.
- ***Author editing mode*** - The visual **Author** mode is also available for Relax NG schema files, presenting the schema similar to the Relax NG compact syntax. It links to imported schemas and external references. Embedded Schematron is also supported in Relax NG schemas with XML syntax.

For information about applying and detecting schemas, see *Associating a Schema to XML Documents* on page 674.

Related Information:

Associating a Schema to XML Documents on page 674

Editing Relax NG Schema in the Master Files Context

Smaller interrelated modules that define a complex Relax NG Schema cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, an element defined in a main schema document is not visible when you edit an included module. Oxygen XML Editor provides the support for defining the main module (or modules), thus allowing you to edit any of the imported/included schema files in the context of the larger schema structure.

You cat set a main Relax NG document either using the *master files support from the* ***Project*** *view*, or using a validation scenario.

To set a *master file* using a validation scenario, add validation units that point to the main schemas. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main schema. In this case, it considers the current module as the main schema.

The advantages of editing in the context of *master file* include:

- Correct validation of a module in the context of a larger schema structure.

- *Content Completion Assistant* displays all the referable components valid in the current context. This include components defined in modules other than the currently edited one.
- The ***Outline** view* displays the components collected from the entire schema structure.

Related Information:

Creating a New Validation Scenario on page 663
XML Schema Outline View on page 396

Relax NG Schema Diagram Editor

This section explains how to use the graphical diagram editor for Relax NG schemas.

Introduction to Relax NG Schema Diagram Editor

Oxygen XML Editor provides a simple, expressive, and easy-to-read schema diagram editor for Relax NG schemas.

With this new feature you can easily develop complex schemas, print them on multiple pages or save them as JPEG, PNG, or BMP images. It helps both schema authors in developing the schema and content authors who are using the schema to understand it.

Oxygen XML Editor is the only XML editor to provide a side by side source and diagram presentation and have them real-time synchronized:

- The changes you make in the Editor are immediately visible in the Diagram (no background parsing).
- Changing the selected element in the diagram selects the underlying code in the source editor.

Full Model View

When you create a new schema document or open an existing one, the editor panel is divided in two sections: one containing the schema diagram and the second the source code. The schema diagram editor has two tabs that offer a **Full Model View** and ***Logical Model View***.

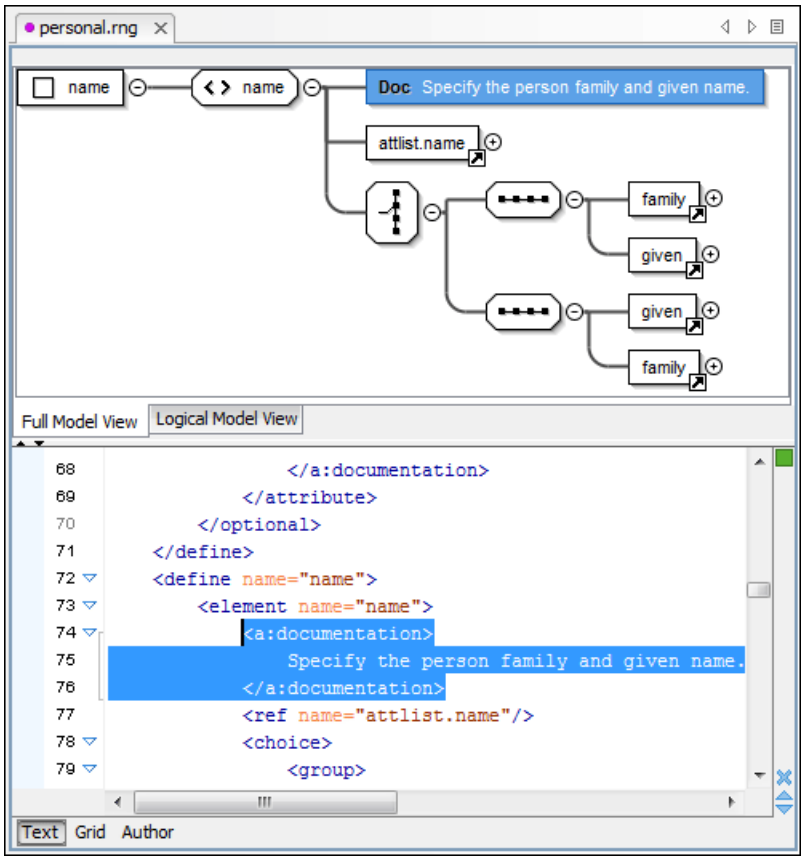

Figure 544: Relax NG Schema Editor - Full Model View

The following references can be expanded in place: patterns, includes, and external references. This expansion mechanism, coupled with the synchronization support, makes the schema navigation easy.

All the element and attribute names are editable by double-clicking the names.

Logical Model View

The **Logical Model View** presents the compiled schema in the form of a single pattern. The patterns that form the element content are defined as top level patterns with generated names. These names are generated depending of the elements name class.

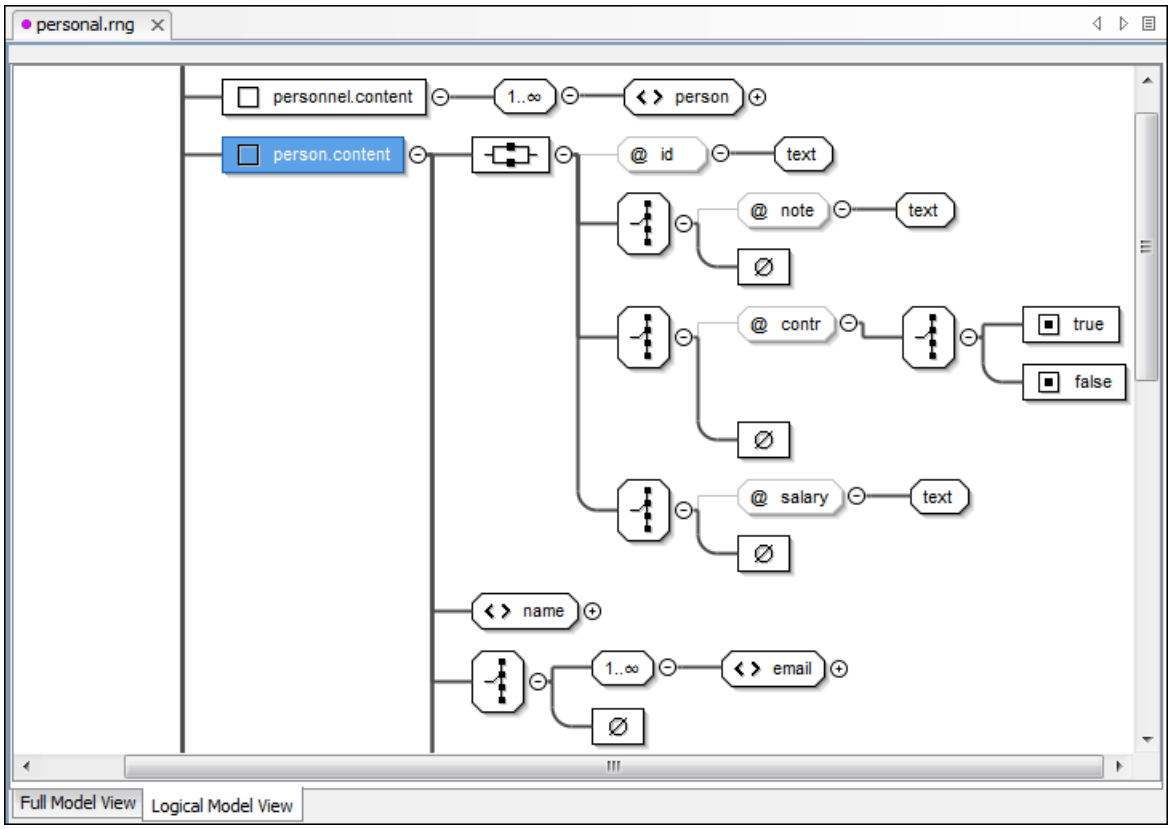

Figure 545: Logical Model View for a Relax NG Schema

Symbols Used in the Schema Diagram

The views in the schema diagram editor renders all the Relax NG schema patterns with the following intuitive symbols:

- 

- `define` pattern with the `name` attribute set to the value shown inside the rectangle (in this example `name`).
- 

- `define` pattern with the `combine` attribute set to `interleave` and the `name` attribute set to the value shown inside the rectangle (in this example `attlist.person`).
- 

- `define` pattern with the `combine` attribute set to `choice` and the `name` attribute set to the value shown inside the rectangle (in this example `attlist.person`).
- 

- `element` pattern with the `name` attribute set to the value shown inside the rectangle (in this example `name`).
- 

- `attribute` pattern with the `name` attribute set to the value shown inside de rectangle (in this case `note`).

- 

- `ref` pattern with the `name` attribute set to the value shown inside the rectangle (in this case `family`).
- 

- `oneOrMore` pattern.
- 

- `zeroOrMore` pattern.
- 

- `optional` pattern.
- 
- `choice` pattern.
- 

- `value` pattern (for example, used inside a `choice` pattern).
- 
- `group` pattern.
- 

- A pattern from the Relax NG Annotations namespace (http://relaxng.org/ns/compatibility/annotations/1.0) that is treated as a documentation element in a Relax NG schema.
- 

- `text` pattern.
- 

- `empty` pattern.

Actions Available in the Schema Diagram Editor

When editing Relax NG schemas in ***Full Model View***, the contextual menu offers the following actions:

Append child

Appends a child to the selected component.

Insert Before

Inserts a component before the selected component.

Insert After

Inserts a component after the selected component.

Edit attributes

Edits the attributes of the selected component.

Remove

Removes the selected component.

Show only the selected component

Depending on its state (selected/not selected), either the selected component or all the diagram components are shown.

Show Annotations

Depending on its state (selected/not selected), the documentation nodes are shown or hidden.

Auto expand to references

This option controls how the schema diagram is automatically expanded. If you select it and then edit a top-level element or you make a refresh, the diagram is expanded until it reaches referenced components. If this option is left unchecked, only the first level of the diagram is expanded, showing the top-level elements. For large schemas, the editor disables this option automatically.

Collapse Children

Collapses the children of the selected view.

Expand Children

Expands the children of the selected view.

Print Selection

Prints the selected view.

Save as Image

Saves the current selection as JPEG, BMP, SVG or PNG image.

Refresh

Refreshes the schema diagram according to the changes in your code. They represent changes in your imported documents or changes that are not reflected automatically in the compiled schema).

If the schema is not valid, you see only an error message in the ***Logical Model View*** instead of the diagram.

Validating Relax NG Schema Documents

By default, Relax NG schema files are validated as you type. To change this, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Document Checking**, and deselect the ***Enable automatic validation** option*.

To validate a Relax NG schema document manually, select the **Validate** action from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu. When Oxygen XML Editor validates a Relax NG schema file, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Related Information:

Presenting Validation Errors in Text Mode on page 227

Content Completion in Relax NG Schemas

The intelligent *Content Completion Assistant* allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.

The *Content Completion Assistant* is enabled by default. To disable it, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Content Completion**, and deselect the ***Enable content completion** option*.

When active, the *Content Completion Assistant* displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut. You can navigate through the list of proposals by using the **Up** and **Down** keys on your keyboard. For each selected item in the list, the *Content Completion Assistant* displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected content in **Text** mode, do one of the following:

- Press **Enter** or **Tab** to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.
- Press **Ctrl + Enter (Command + Enter on OS X)** to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

If you are using the concept of *master files* to import/include modules, the *Content Completion Assistant* collects its components starting from the *master files*. The *master files* can be defined in the project or in the associated validation scenario. For more information about the *Master Files* support in Oxygen XML Editor, see *Defining Master Files at Project Level*.

The *Content Completion Assistant* also offers additional information for the element and attribute proposals in the form of schema annotations that is displayed in a tooltip.

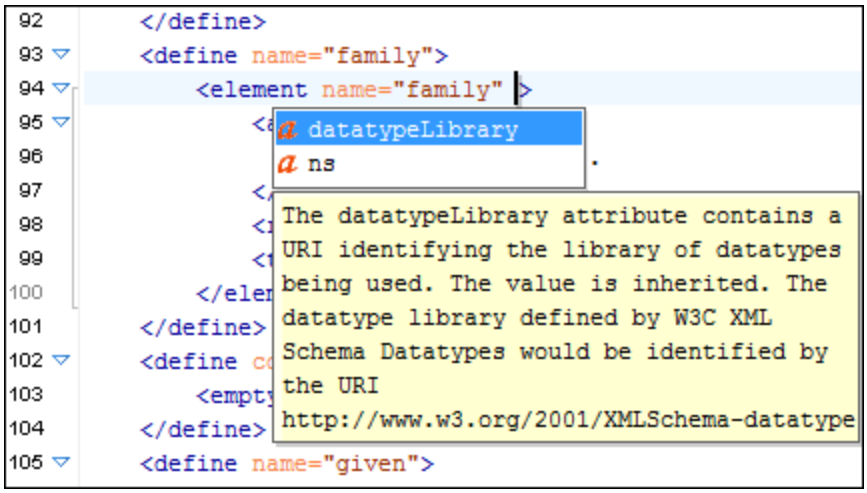

Figure 546: Relax NG Content Completion Assistant

Syntax Highlighting in Relax NG Schemas

Oxygen XML Editor supports syntax highlighting in Relax NG schemas to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for Relax NG schemas, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **XML** section in the top pane (for RELAX NG Compact Syntax schemas, select and expand the **RNC** section).
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XML** tab in the **Preview** pane to see the effects of your changes (for RELAX NG Compact Syntax schemas, the tab is **RNC**).

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the ***Editor > Syntax Highlight > Elements/ Attributes by Prefix** preferences page*.

Related Information:

Syntax Highlight Preferences on page 105

Quick Fixes for DTD, XSD, and Relax NG Errors

Oxygen XML Editor offers *Quick Fixes* for common errors that appear in XML documents that are validated against DTD, XSD, or Relax NG schemas.

Note: For XML documents validated against XSD schemas, the *Quick Fixes* are only available if you use the default Xerces validation engine.

Quick Fixes are available in **Text** mode and **Author** mode.

Oxygen XML Editor provides *Quick Fixes* for numerous types of problems, including the following:

Problem Type	Available Quick Fixes
A specific element is required in the current context	Insert the required element
An element is invalid in the current context	Remove the invalid element
The content of the element should be empty	Remove the element content

Problem Type	Available Quick Fixes
An element is not allowed to have child elements	Remove all child elements
Text is not allowed in the current element	Remove the text content
A required attribute is missing	Insert the required attribute
An attribute is not allowed to be set for the current element	Remove the attribute
The attribute value is invalid	Propose the correct attribute values
ID value is already defined	Generate a unique ID value
References to an invalid ID	Change the reference to an already defined ID

Related Information:

Schematron Quick Fixes (SQF) on page 674

Relax NG Outline View

The **Outline** view for Relax NG schemas presents a list with the patterns that appear in the diagram in both the ***Full Model View*** and ***Logical Model View*** cases and it allows for quick access to a component by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Figure 547: Relax NG Outline View

This view has two modes, with the tree showing either the XML structure or the defined pattern (components) collected from the current document. By default, the **Outline** view presents the components.

When the **Show components** option is selected in the **Settings** menu on the **Outline** view toolbar, the following option is available:

Show XML structure

Shows the XML structure of the current document in a tree-like manner.

The following actions are available in the **Settings** menu on the **Outline** view toolbar when the **Show XML structure** option is selected:

Filter returns exact matches

The text filter of the **Outline** view returns only exact matches.

Selection update on cursor move

Allows a synchronization between **Outline** view and schema diagram. The selected view from the diagram will be also selected in the **Outline** view.

Show components

Shows the defined pattern collected from the current document.

Flat presentation mode of the filtered results

When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions

Show/hide comments and processing instructions in the **Outline** view.

Show element name

Show/hide element name.

Show text

Show/hide additional text content for the displayed elements.

Show attributes

Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from *the Outline preferences panel*.

Configure displayed attributes

Displays the ***XML Structured Outline** preferences page*.

The following contextual menu actions are also available in the **Outline** view when the **Show XML structure** option is selected in the **Settings** menu:

Append Child

Displays a list of elements that you can insert as children of the current element.

Insert Before

Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After

Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes

Opens a dialog box that allows you to edit the attributes of the currently selected component.

Toggle Comment

Comments/uncomments the currently selected element.

Search references

Searches for the references of the currently selected component.

Search references in

Searches for the references of the currently selected component in the context of a scope that you define.

Component dependencies

Opens the ***Component Dependencies*** *view* that displays the dependencies of the currently selected component.

Rename Component in

Renames the currently selected component in the context of a scope that you define.

Cut

Cuts the currently selected component.

Copy

Copies the currently selected component.

Delete

Deletes the currently selected component.

Expand More

Expands the structure of a component in the **Outline** view.

Collapse All

Collapses the structure of all the component in the **Outline** view.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (*, ?) and separate multiple patterns with commas.

RNG Resource Hierarchy/Dependencies View

The **Resource Hierarchy/Dependencies** view allows you to see the hierarchy/dependencies for a schema. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

If you want to see the hierarchy of a schema, select the desired schema in the ***Project*** *view* and choose **Resource Hierarchy** from the contextual menu.

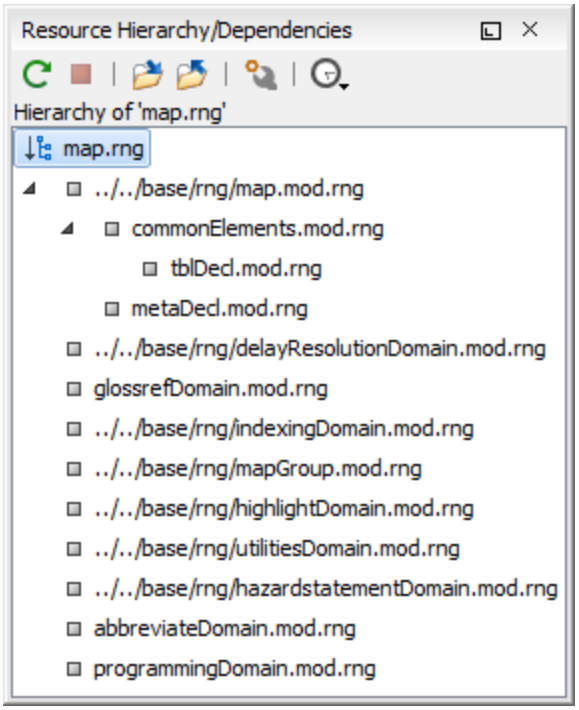

Figure 548: Resource Hierarchy/Dependencies View - hierarchy for `map.rng`

If you want to see the dependencies of a schema, select the desired schema in the **Project** view and choose **Resource Dependencies** from the contextual menu.

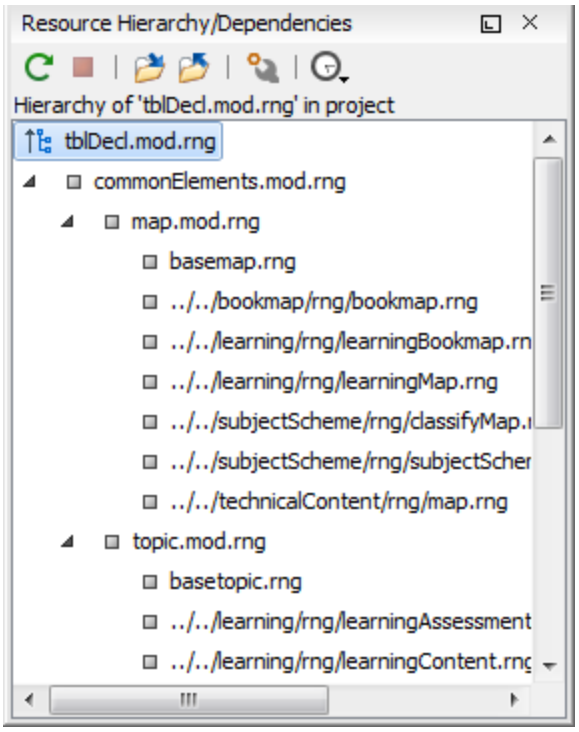

Figure 549: Resource Hierarchy/Dependencies View - Dependencies for `tblDecl.mod.rng`

The following actions are available in the **Resource Hierarchy/Dependencies** view:

Refresh

Refreshes the Hierarchy/Dependencies structure.

Stop

Stops the hierarchy/dependencies computing.

Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

Renames the selected resource.

Show Resource Hierarchy

Shows the hierarchy for the selected resource.

Show Resource Dependencies

Shows the dependencies for the selected resource.

 **Add to Master Files**

Adds the currently selected resource in *the **Master Files** directory*.

Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon .

Note: The **Move resource** or **Rename resource** actions give you the option to *update the references to the resource*.

Related Information:

Working with Modular XML Files in the Master Files Context on page 692

Search and Refactor Operations Scope on page 691

Moving/Renaming RNG Resources

You can move and rename a resource presented in the **Resource/Hierarchy Dependencies** view, using the **Rename resource** and **Move resource** refactoring actions from the contextual menu.

When you select the **Rename** action in the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Rename resource** dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references** - Select this option to update the references to the resource you are renaming.

When you select the **Move** action from the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Move resource** dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name.

If the **Update references of the moved resource(s)** option is selected, a **Preview** option (which opens the **Preview** dialog box) is available for both actions. The **Preview** dialog box presents a list with the resources that are updated.

Note: Updating the references of a resource that is resolved through a catalog is not supported. Also, the update references operation is not supported if the path to the renamed or moved resource contains entities.

Relax NG Schema Component Dependencies View

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

To see the dependencies of a RelaxNG component:

1. Right-click the desired component in the editor or **Outline** view.
2. Select the **Component Dependencies** action from the contextual menu.

The action is available for all named defines.

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon .

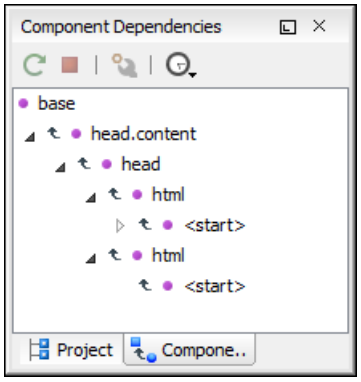

Figure 550: Component Dependencies View - Hierarchy for `base.rng`

The **Component Dependencies** view includes the following toolbar actions:

Refresh

Refreshes the dependencies structure.

Stop

Stops the dependency computation.

Configure

Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History

Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

Go to First Reference

Selects the first reference of the currently selected component in the dependencies tree.

Go to Component

Shows the definition of the currently selected component in the dependencies tree.

Related Information:

Search and Refactor Operations Scope on page 691

Searching and Refactoring Actions in RNG Schemas

Search Actions

The following search actions can be applied on named *defines* and are available from the **Search** submenu in the contextual menu of the current editor or from the **Document** > **References** menu:

- **Search References** - Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.
- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the **Document** > **Schema** menu:

- **Go to Definition** - Moves the cursor to the definition of the current element in the Relax NG (full syntax) schema.

  Note: You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

Refactoring Actions

The following refactoring actions can be applied on named *defines* and are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document** > **Refactoring** menu:

- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.
- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

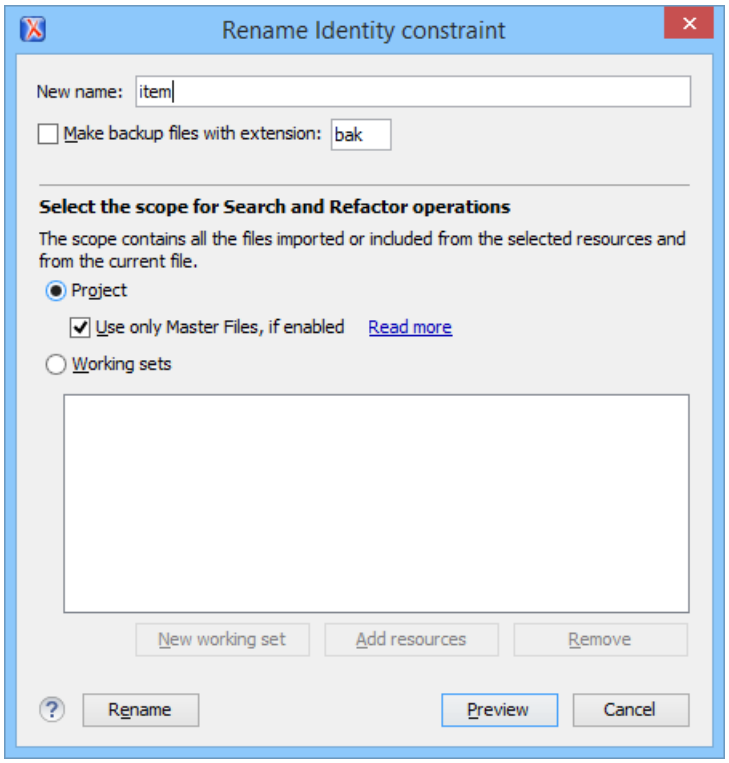

Figure 551: Rename Identity Constraint Dialog Box

RNG Quick Assist Support

The *Quick Assist support* improves the development work flow, offering fast access to the most commonly used actions when you edit schema documents.

The *Quick Assist feature* is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon ( ) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the *quick assist* menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

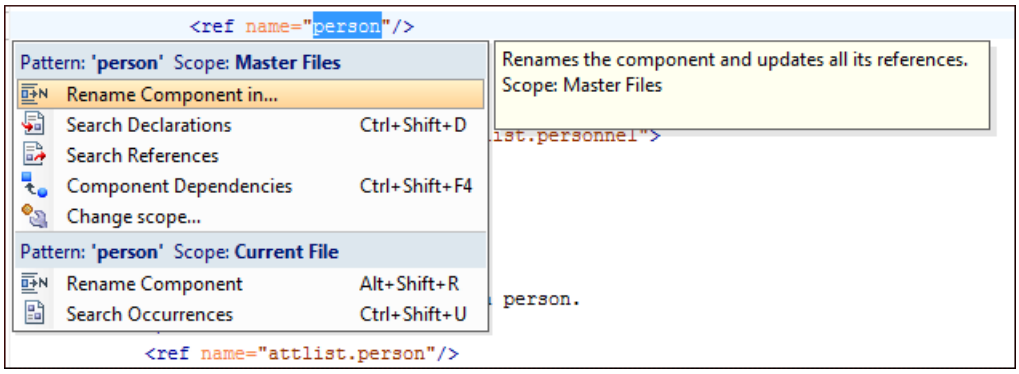

Figure 552: RNG Quick Assist Support

The *Quick Assist* support offers direct access to the following actions:

Rename Component in

Renames the component and all its dependencies.

Search Declarations

Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

Search References

Searches all references of the component in a predefined scope.

Component Dependencies

Searches the component dependencies in a predefined scope.

Change Scope

Configures the scope that will be used for future search or refactor operations.

Rename Component

Allows you to rename the current component in-place.

Search Occurrences

Searches all occurrences of the component within the current file.

Configuring a Custom Datatype Library for a RELAX NG Schema

A RELAX NG schema can declare a custom datatype library for the values of elements found in XML document instances. The datatype library must be developed in Java and it must implement the interface *specified on the www.thaiopensource.com website.*

The *JAR* file containing the custom library and any other dependent *JAR* file must be added to the classpath of the application, that is the *JAR* files must be added to the folder *[OXYGEN_INSTALL_DIR]*`/lib` .

To load the custom library, restart Oxygen XML Editor.

Editing NVDL Schemas

Some complex XML documents are composed by combining elements and attributes from namespaces. Furthermore, the schemas that define these namespaces are not even developed in the same schema language. In such cases, it is difficult to specify in the document all the schemas that must be taken into account for validation of the XML document or for content completion. An NVDL (Namespace Validation Definition Language) schema can be used. This schema allows the application to combine and interleave multiple schemas of different types (W3C XML Schema, RELAX NG schema, Schematron schema) in the same XML document.

Oxygen XML Editor offers support for editing NVDL schema files in the following editing modes:

- ***Text editing mode*** - Allows you to edit NVDL schema files in a source editing mode, along with a schema design pane with two tabs that offer a ***Full Model View*** and ***Logical Model View***.
- ***Grid editing mode*** - Displays NVDL schema files in a structured spreadsheet-like grid.
- **Author editing mode** - The visual **Author** mode is also available for Relax NG schema files, presenting them in a compact and easy to understand representation.

For information about applying and detecting schemas, see *Associating a Schema to XML Documents* on page 674.

Related Information:

Associating a Schema to XML Documents on page 674

NVDL Schema Diagram

This section explains how to use the graphical diagram of a NVDL schema.

Introduction to NVDL Schema Diagram Editor

Oxygen XML Editor provides a simple, expressive, and easy-to-read schema diagram editor for NVDL schemas.

With this new feature you can easily develop complex schemas, print them on multiple pages or save them as JPEG, PNG, and BMP images. It helps both schema authors in developing the schema and content authors that are using the schema to understand it.

Oxygen XML Editor is the only XML Editor to provide a side by side source and diagram presentation and have them real-time synchronized:

- The changes you make in the Editor are immediately visible in the Diagram (no background parsing).
- Changing the selected element in the diagram, selects the underlying code in the source editor.

Full Model View

When you create a schema document or open an existing one, the editor panel is divided in two sections: one containing the schema diagram and the second the source code. The diagram view has two tabbed panes offering a **Full Model View** and a ***Logical Model View***.

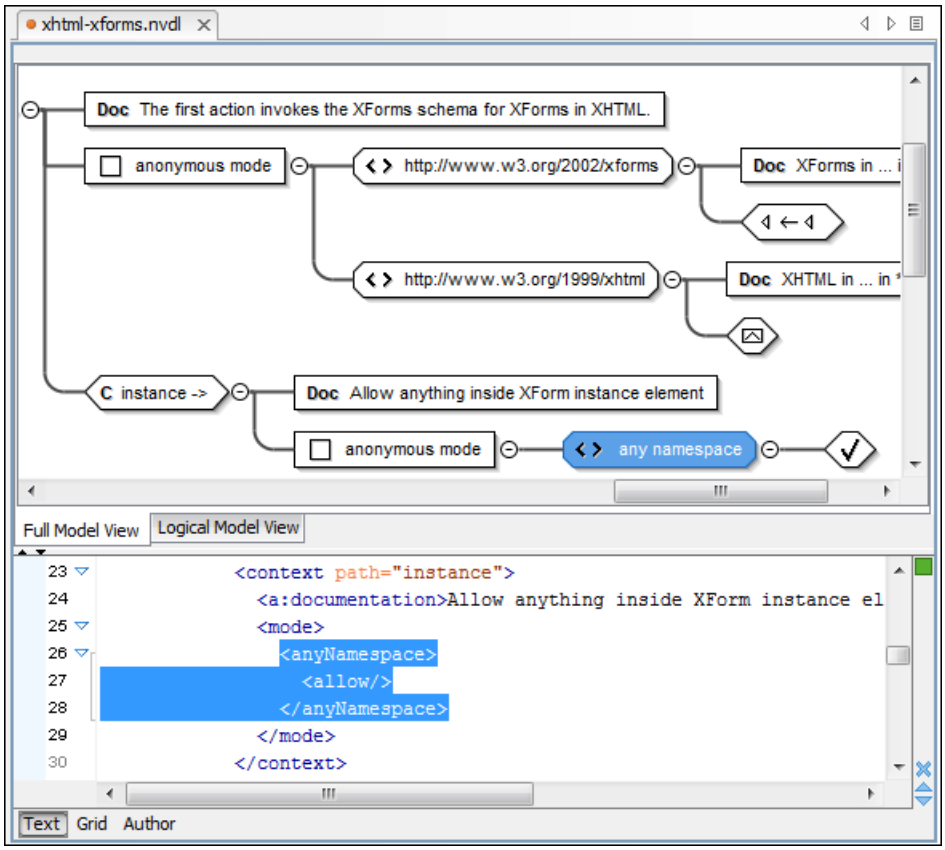

Figure 553: NVDL Schema Editor - Full Model View

The **Full Model View** renders all the NVDL elements with intuitive icons. This representation coupled with the synchronization support makes the schema navigation easy.

Double-click any diagram component to edit its properties.

Logical Model View

The **Logical Model View** presents the compiled schema in the form of a single pattern. The patterns that form the element content are defined as top level patterns with generated names. These names are generated depending of the elements name class.

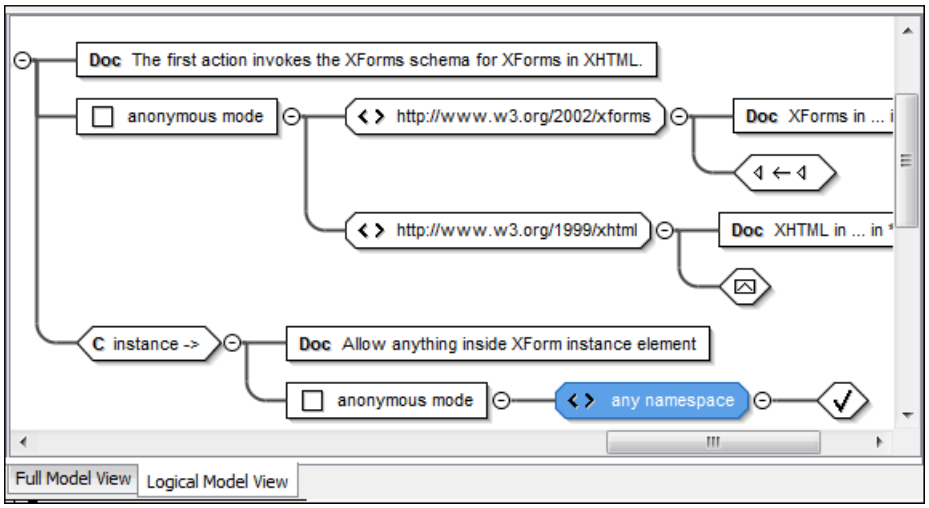

Figure 554: Logical Model View for an NVDL Schema

Actions Available in the Diagram Editor

The contextual menu offers the following actions:

Show only the selected component

Depending on its state (selected/not selected), either the selected component or all the diagram components are shown.

Show Annotations

Depending on its state (selected/not selected), the documentation nodes are shown or hidden.

Auto expand to references

This option controls how the schema diagram is automatically expanded. For instance, if you select it and then edit a top-level element or you trigger a diagram refresh, the diagram will be expanded until it reaches the referenced components. If this option is left unchecked, only the first level of the diagram is expanded, showing the top-level elements. For large schemas, the editor disables this option automatically.

Collapse Children

Collapses the children of the selected view.

Expand Children

Expands the children of the selected view.

Print Selection

Prints the selected view.

Save as Image

Saves the current selection as image, in JPEG, BMP, SVG or PNG format.

Refresh

Refreshes the schema diagram according to the changes in your code (changes in your imported documents or those that are not reflected automatically in the compiled schema).

If the schema is not valid, you see only an error message in the ***Logical Model View*** instead of the diagram.

Validating NVDL Schema Documents

By default, NVDL schema files are validated as you type. To change this, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Document Checking**, and deselect the ***Enable automatic validation** option*.

To validate an NVDL schema document manually, select the **Validate** action from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu. When Oxygen XML Editor validates an NVDL schema file, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Related Information:

Validating XML Documents Against a Schema on page 656

Content Completion in NVDL Schemas

The intelligent *Content Completion Assistant* allows you to quickly identify and insert elements, attributes, and attribute values that are valid in the current editing context. All available proposals are listed in a pop-up menu displayed at the current cursor position.

The *Content Completion Assistant* is enabled by default. To disable it, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Content Completion**, and deselect the ***Enable content completion** option*.

When active, the *Content Completion Assistant* displays a list of context-sensitive proposals valid at the current cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut. You can navigate through the list of proposals by using the **Up** and **Down** keys on your keyboard. For each selected item in the list, the *Content Completion Assistant* displays a documentation window. You can customize the size of the documentation window by dragging its top, right, and bottom borders.

To insert the selected content in **Text** mode, do one of the following:

- Press **Enter** or **Tab** to insert both the start and end tags and position the cursor inside the start tag in a position suitable for inserting attributes.
- Press **Ctrl + Enter (Command + Enter on OS X)** to insert both the start and end tags and positions the cursor between the tags in a position where you can start typing content.

If you are using the concept of *master files* to import/include modules, the *Content Completion Assistant* collects its components starting from the *master files*. The *master files* can be defined in the project or in the associated validation scenario. For more information about the *Master Files* support in Oxygen XML Editor, see *Defining Master Files at Project Level*.

The *Content Completion Assistant* also offers additional information for the element and attribute proposals in the form of schema annotations that is displayed in a tooltip.

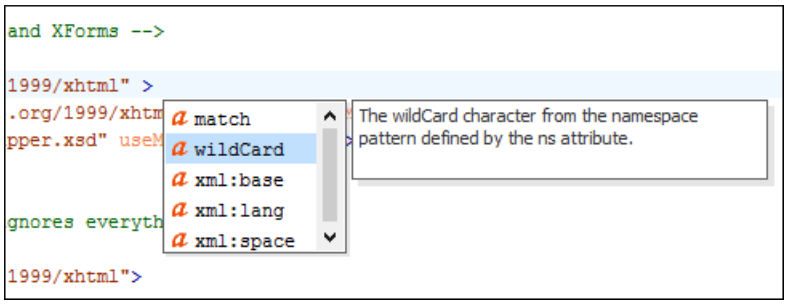

Figure 555: NVDL Content Completion Assistant

Syntax Highlighting in NVDL Schemas

Oxygen XML Editor supports syntax highlighting in NVDL schemas to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for NVDL schemas, follow these steps:

1. *Open the **Preferences** dialog box **(Options** > **Preferences)***.
2. Go to ***Editor** > **Syntax Highlight***.
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XML** tab in the **Preview** pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the ***Editor** > **Syntax Highlight** > **Elements/Attributes by Prefix** preferences page*.

Related Information:

Syntax Highlight Preferences on page 105

NVDL Outline View

The **Outline** view for NVDL schemas presents a list with the named or anonymous rules that appear in the diagram and it allows for quick access to a rule by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

NVDL Schema Component Dependencies View

The **Component Dependencies** view allows you to see the dependencies for a selected component. This is helpful if you want to see where components are used in the entire hierarchy. For example, if you want to find all the references where a given component is used.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

To see the dependencies of an NVDL component:

1. Right-click the desired component in the editor or **Outline** view.

2. Select the **Component Dependencies** action from the contextual menu.

The action is available for all named modes.

If a component contains multiple references, a small table is displayed at the bottom of the view that contains all the references. When a recursive reference is encountered, it is marked with a special icon .

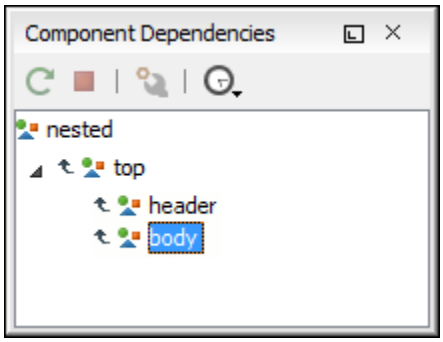

Figure 556: Component Dependencies View - Hierarchy for `test.nvdl`

The **Component Dependencies** view includes the following toolbar actions:

Refresh
Refreshes the dependencies structure.

Stop
Stops the dependency computation.

Configure
Allows you to choose the search scope for computing the dependencies structure. This is helpful for making sure all imported/included resources are computed.

History
Allows you to select from a list of the most recently used dependency computations.

In addition, the following actions are available in the contextual menu:

Go to First Reference
Selects the first reference of the currently selected component in the dependencies tree.

Go to Component
Shows the definition of the currently selected component in the dependencies tree.

Searching and Refactoring Actions in NVDL Schemas

Search Actions

The following search actions can be applied on `name`, `useMode`, and `startMode` attributes and are available from the **Search** submenu in the contextual menu of the current editor or from the **Document** > **References** menu:

- **Search References** - Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.

- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.
- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

The following action is available from the contextual menu and the **Document** > **Schema** menu:

- **Go to Definition** - Moves the cursor to its definition in the schema used by the NVDL to validate it.

  Note: You can also use the **Ctrl + Single-Click (Command + Single-Click on OS X)** shortcut on a reference to display its definition.

Refactoring Actions

The following refactoring actions can be applied on `name`, `useMode`, and `startMode` attributes and are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document** > **Refactoring** menu:

- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.
- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

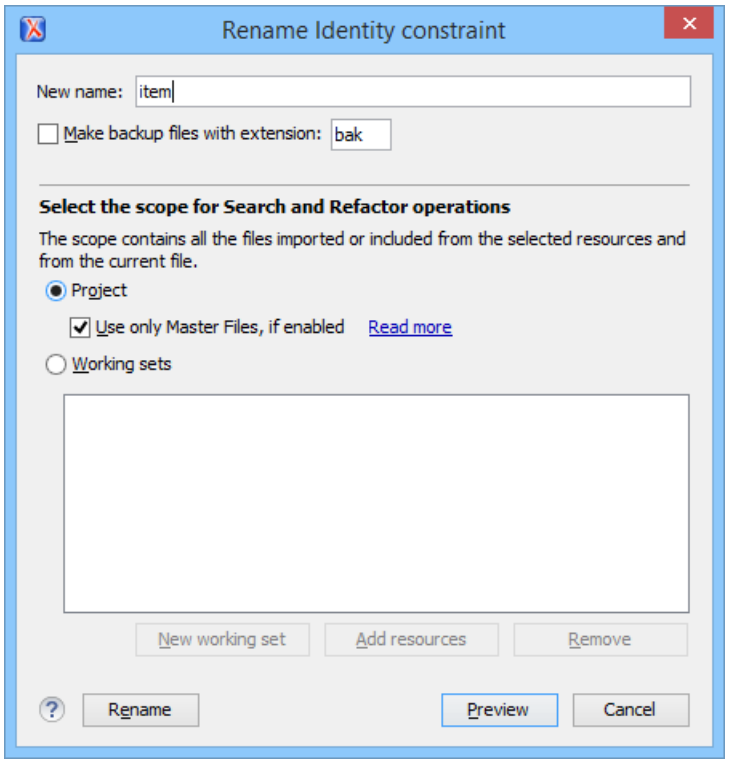

Figure 557: Rename Identity Constraint Dialog Box

Editing JSON Documents

This section explains the features of the Oxygen XML Editor JSON Editor and how to use them.

Editing JSON Documents in Text Mode

When editing JSON documents in the **Text** editing mode, the *usual text editing actions* are available, along with other editor specific actions, including:

- *Find / Replace*
- *Drag and Drop*
- *Validation*
- *Format and Indent (Pretty Print)*

Note: You can run XPath expressions on opened JSON documents, but in **Text** mode the XPath results cannot be mapped in the document. However, they can be mapped in the **Grid** editing mode. You can use the **Grid** button at the bottom of the editor panel to switch to that editing mode.

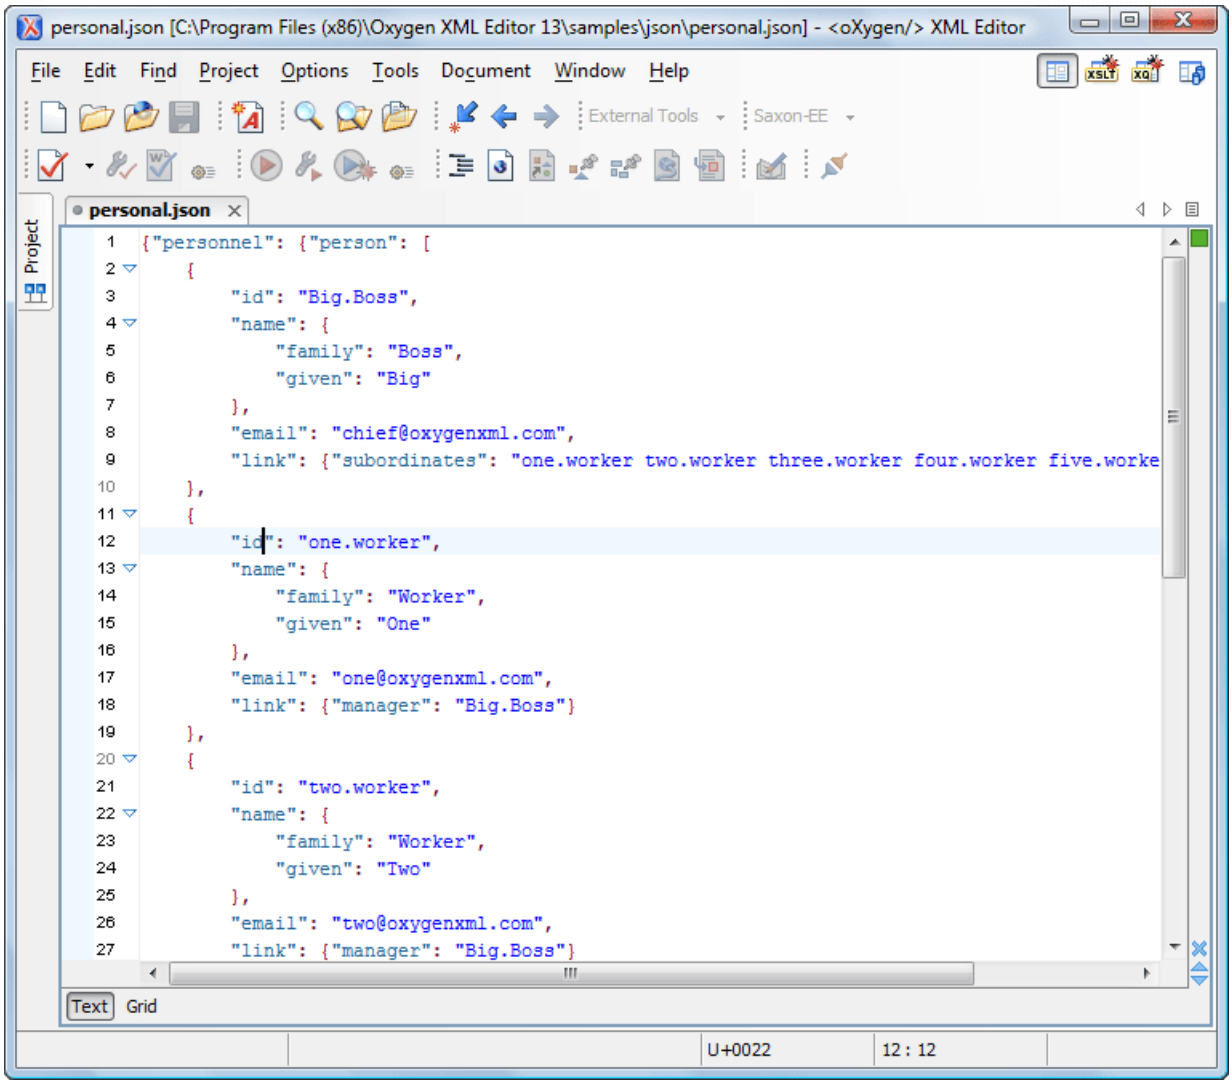

Figure 558: JSON Editor Text Mode

Related Information:

Text Preferences on page 79

Editing JSON Documents in Grid Mode on page 889

Editing JSON Documents in Grid Mode

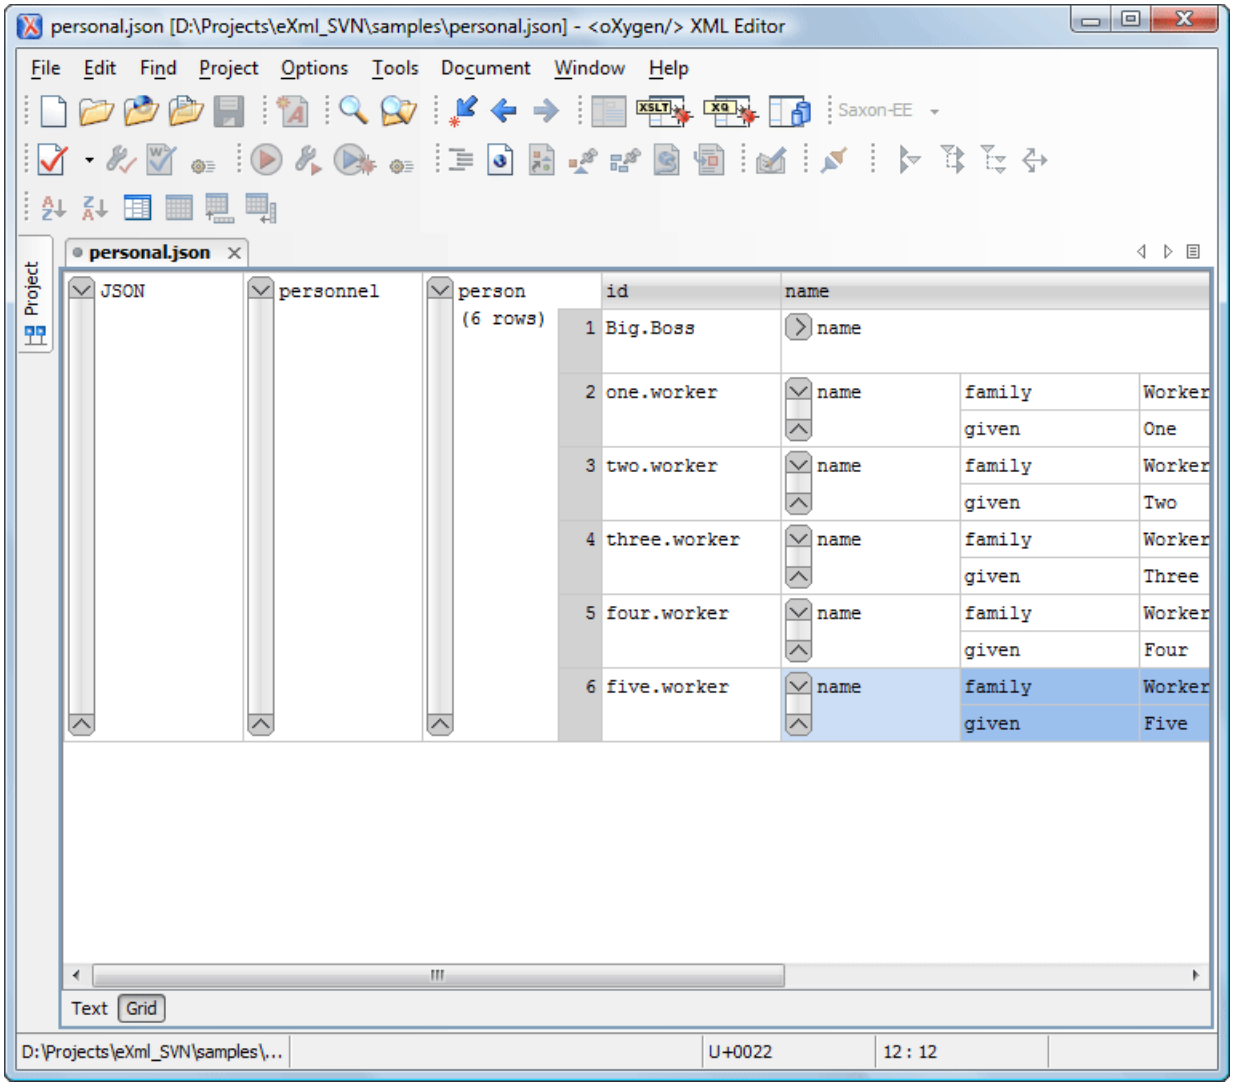

Figure 559: JSON Editor Grid Mode

Oxygen XML Editor allows you to view and edit the JSON documents in the ***Grid*** *mode*. The JSON is represented in **Grid** mode as a compound layout of nested tables in which the JSON data and structure can be easily manipulated with table-specific operations or drag and drop operations on the grid components. You can also use the following JSON-specific contextual actions:

Array

Useful when you want to convert a JSON *value* to *array*.

Insert value before

Inserts a value before the currently selected one.

Insert value after

Inserts a value after the currently selected one.

Append value as child

Appends a value as a child of the currently selected value.

You can *customize the JSON grid appearance* according to your needs. For instance, you can change the font, the cell background, foreground, or even the colors from the table header gradients. The default width of the columns can also be changed.

Related Information:

Grid Editing Mode on page 245

Grid Preferences on page 80

Validating JSON Documents

Oxygen XML Editor includes a built-in JSON validator (based on the free JAVA source code available on www.json.org), integrated with the general validation support.

Related Information:

Presenting Validation Errors in Text Mode on page 227

Document Checking Preferences on page 96

Syntax Highlighting in JSON Documents

Oxygen XML Editor supports syntax highlighting in JSON files to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for JSON files, follow these steps:

1. *Open the **Preferences** dialog box **(Options** > **Preferences)***.
2. Go to ***Editor** > **Syntax Highlight***.
3. Select and expand the **JSON** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Related Information:

Syntax Highlight Preferences on page 105

Folding in JSON

In a large JSON document, the data enclosed in the '{' and '}' characters can be collapsed so that only the needed data remain in focus. The *folding features available for XML documents* are available in JSON documents.

JSON Outline View

The **Outline** view for JSON documents displays the list of all the components of the JSON document you are editing. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

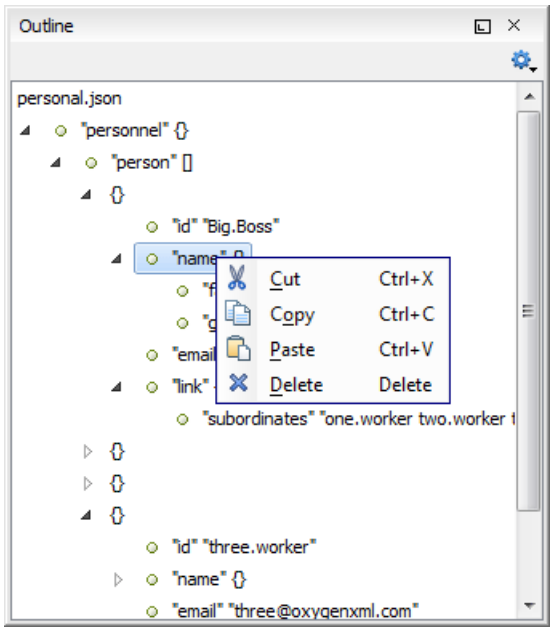

Figure 560: JSON Outline View

The following actions are available in the contextual menu of the JSON **Outline** view:

- **Cut**
- **Copy**
- **Paste**
- **Delete**

The **Settings** menu on the JSON **Outline** view toolbar includes a **Selection update on cursor move** option that allows you to control the synchronization between the **Outline** view and source the document. Oxygen XML Editor synchronizes the selection in the **Outline** view with the cursor moves or the changes you make in the JSON editor. Selecting one of the components from the **Outline** view also selects the corresponding item in the source document.

JSON to XML Converter

Oxygen XML Editor includes a useful and simple tool for converting JSON files to XML. It can be found in the **Tools** menu.

To convert a JSON document to XML, follow these steps:

1. Select the **JSON to XML** action from the **Tools** menu.
   The **JSON to XML** dialog box is displayed:

   Figure 561: JSON to XML Dialog Box
2. Choose or enter the **Input URL** of the JSON document.
3. Choose the path of the **Output file** that will contain the resulting XML document.
4. Select the **Open in Editor** option to open the resulting XML document in the main editing pane.
5. Click the **Convert** button.

The original JSON document is now converted to an XML document.

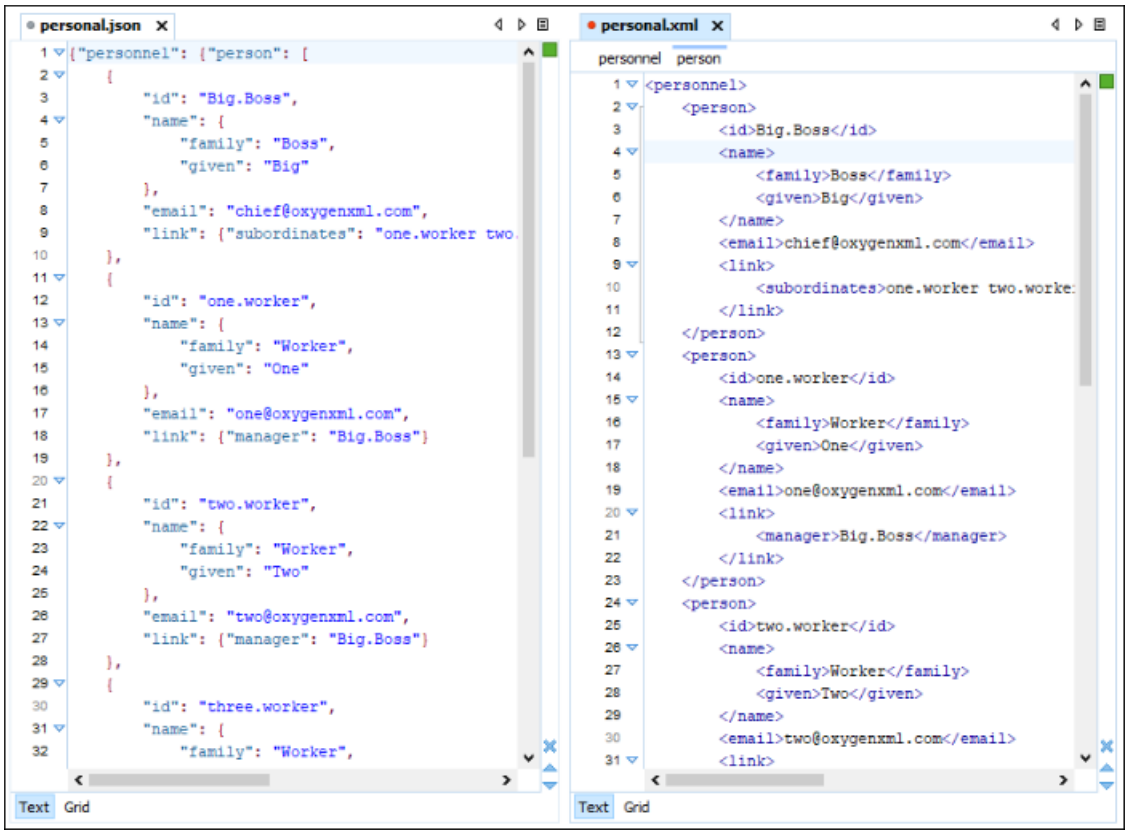

Figure 562: Example: XML to JSON Operation Result

XML to JSON Converter

Oxygen XML Editor includes a useful and simple tool for converting XML files to JSON. It can be found in the **Tools** menu.

To convert an XML document to JSON, follow these steps:

1. Select the **XML to JSON** action from the **Tools** menu.

   The **XML to JSON** dialog box is displayed:

   Figure 563: XML to JSON Dialog Box
2. Choose or enter the **Input URL** of the XML document.
3. Choose the path of the **Output file** that will contain the resulting JSON document.
4. Select the **Open in Editor** option to open the resulting JSON document in the main editing pane.
5. Click the **Convert** button.

The original XML document is now converted to a JSON document.

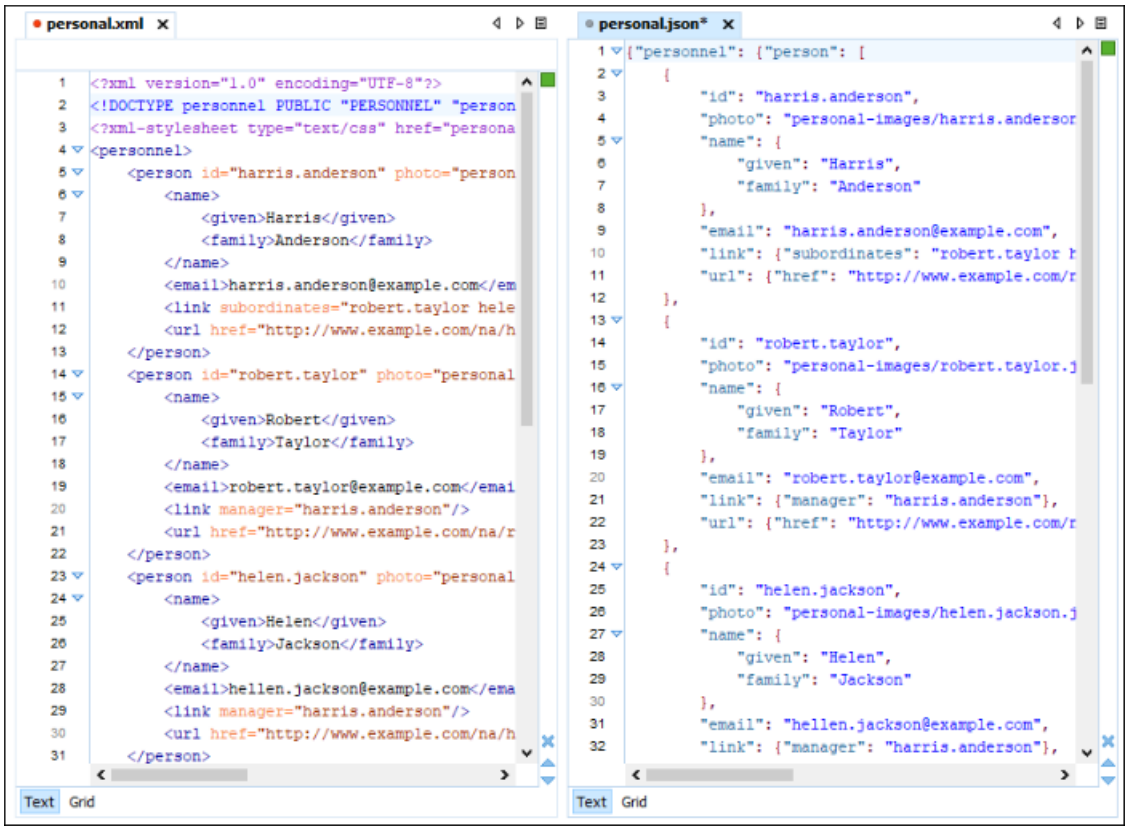

Figure 564: Example: XML to JSON Operation Result

Editing StratML Documents

Strategy Markup Language (StratML) is an XML vocabulary and schema for strategic plans. Oxygen XML Editor supports StratML Part 1 (Strategic Plan) and StratML Part 2 (Performance Plans and Reports) and provides templates for the following documents:

- **Strategic Plan** (StratML Part 1)
- **Performance Plan** (StratML Part 2)
- **Performance Report** - (StratML Part 2)
- **Strategic Plan** - (StratML Part 2)

You can view the components of a StratML document in the ***Outline*** *view*. Oxygen XML Editor implements a default XML with XSLT transformation scenario for this document type, called StratML to HTML.

Editing XLIFF Documents

XLIFF (*XML Localization Interchange File Format*) is an XML-based format that was designed to standardize the way multilingual data is passed between tools during a localization process. Oxygen XML Editor provides the following support for editing XLIFF documents:

XLIFF Version 1.2 and 2.0 Support:

- New file templates for XLIFF documents.
- A default CSS file (`xliff.css`) used for rendering XLIFF content in **Author** mode is stored in *`[OXYGEN_INSTALL_DIR]`*`/frameworks/xliff/css/`.
- Validation and content completion support using local catalogs. The default catalog (`catalog.xml`) for version 1.2 is stored in *`[OXYGEN_INSTALL_DIR]`*`/frameworks/xliff/xsd/1.2`, and for version 2.0 in *`[OXYGEN_INSTALL_DIR]`*`/frameworks/xliff/xsd/2.0`.

XLIFF Version 2.0 Enhanced Support:

- Support for validating XLIFF 2.0 documents using modules. The default modules are stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/xliff/xsd/2.0/modules`.

Editing JavaScript Documents

This section explains the features of the Oxygen XML Editor JavaScript Editor and how you can use them.

JavaScript Editing Actions

Oxygen XML Editor allows you to create and edit JavaScript files and assists you with useful features such as syntax highlight, content completion, and outline view. To enhance your editing experience, you can select entire blocks (parts of text delimited by brackets) by double-clicking somewhere inside the brackets.

```
90    function change_sides(front) {
91      switch ($('#version-switch').text()) {
92        case 'Original':
93          $('#holder').html($('div .original[id]').html());
94          make_clickable();
95          $('#version-switch').text('Translation 1');
96          break;
97        case 'Translation 1':
98          $('#holder').html($('div .translation[id]').filter(':first').html());
99          $('#version-switch').text('Translation 2');
100         break;
101       case 'Translation 2':
102         $('#holder').html($('div .translation[id]').filter(':last').html());
103         $('#version-switch').text('Original');
104         break;
105       }
106     }
```

Figure 565: JavaScript Editor Text Mode

The contextual menu of the **JavaScript** editor offers the following actions:

Cut

Allows you to cut fragments of text from the editing area.

Copy

Allows you to copy fragments of text from the editing area.

Paste

Allows you to paste fragments of text in the editing area.

Toggle Comment

Allows you to comment a line or a fragment of the JavaScript document you are editing. This option inserts a single comment for the entire fragment you want to comment.

Toggle Line Comment

Allows you to comment a line or a fragment of the JavaScript document you are editing. This option inserts a comment for each line of the fragment you want to comment.

Go to Matching Bracket

Use this option to find the closing, or opening bracket, matching the bracket at the cursor position. When you select this option, Oxygen XML Editor moves the cursor to the matching bracket, highlights its row, and decorates the initial bracket with a rectangle.

Note: A rectangle decorates the opening or closing bracket that matches the current one, at all times.

Source

Allows you to select one of the following actions:

To Lower Case

Converts the selection content to lower case characters.

To Upper Case

Converts the selection content to upper case characters.

Capitalize Lines

Converts to upper case the first character of every selected line.

Join and Normalize Lines

Joins all the rows you select to one row and normalizes the content.

Insert new line after

Inserts a new line after the line at the cursor position.

Modify all matches

Use this option to modify (in-place) all the occurrences of the selected content. When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Open

Allows you to select one of the following actions:

- **Open File at Cursor** - select this action to open the source of the file located at the cursor position
- **Open File at Cursor in System Application** - select this action to open the source of the file located at the cursor position with the application that the system associates with the file

Compare

Select this option to open the **Compare Files** tool to compare the file you are editing with a file you choose in the dialog box.

Folding

When you invoke the contextual menu from the *folding* triangles in the stripe on the left side of the editor, the following actions are available:

Collapse Other Folds (Ctrl + NumPad/ (Command + NumPad/ on OS X))

Folds all the elements except the current element.

Collapse Child Folds (Ctrl + NumPad. (Command + NumPad. on OS X))

Folds the elements indented with one level inside the current element.

Expand Child Folds

Unfolds all child elements of the currently selected element.

Expand All (Ctrl + NumPad* (Command + NumPad* on OS X))

Unfolds all elements in the current document.

Validating JavaScript Files

You have the possibility to validate the JavaScript document you are editing. Oxygen XML Editor uses the Mozilla Rhino library for validation. For more information about this library, go to *http://www.mozilla.org/rhino/doc.html*. The JavaScript validation process checks for errors in the syntax. Calling a function that is not defined is not treated as an error by the validation process. The interpreter discovers this error when executing the faulted line. Oxygen XML Editor can validate a JavaScript document both on-request and automatically.

Content Completion in JavaScript Documents

When you edit a JavaScript document, the *Content Completion Assistant* presents you a list of the elements you can insert at the cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

For an enhanced assistance, JQuery methods are also presented. The following icons decorate the elements in the content completion list of proposals depending on their type:

- f() - function
- V - variable
- ▢ - object
- ● - property
- f() - method

Note: These icons decorate both the elements from the content completion list of proposals and from the ***Outline*** *view*.

Figure 566: JavaScript Content Completion Assistant

The *Content Completion Assistant* collects:

- Method names from the current file and from the library files.
- Functions and variables defined in the current file.

If you edit the content of a function, the content completion list of proposals contains all the local variables defined in the current function, or in the functions that contain the current one.

Syntax Highlighting in JavaScript Documents

Oxygen XML Editor supports syntax highlighting in JavaScript files to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for JavaScript files, follow these steps:

1. *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **JavaScript** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Related Information:

Syntax Highlight Preferences on page 105

JavaScript Outline View

Oxygen XML Editor present a list of all the components of the JavaScript document you are editing in the **Outline** view. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

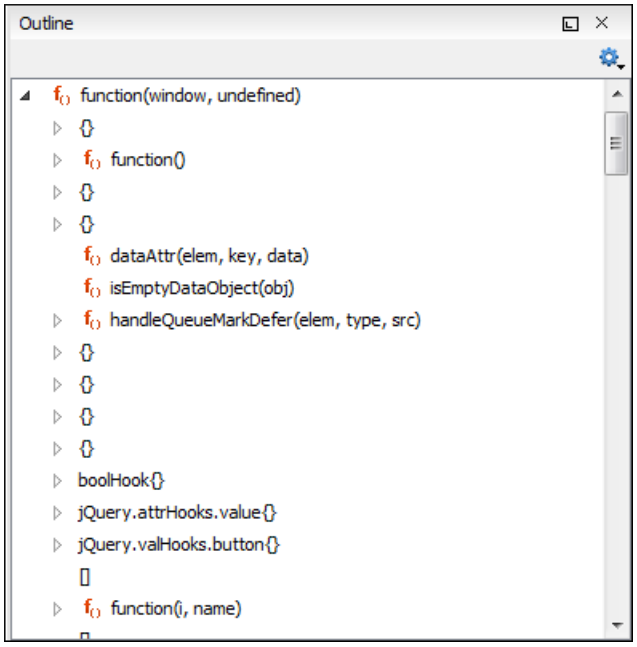

Figure 567: JavaScript Outline View

The following icons decorate the elements in the **Outline** view depending on their type:

- - function
- - variable
- - object
- - property
- - method

The contextual menu of the JavaScript **Outline** view contains the usual **Cut**, **Copy**, **Paste**, and **Delete** actions. From the **Settings** menu, you can select the **Update selection on cursor move** option to synchronize the **Outline** view with the editing area.

Editing XProc Scripts

An XProc script is edited as an XML document that is validated against a RELAX NG schema. If the script has an associated transformation scenario, then the XProc engine from the scenario is invoked as validating engine. The default engine for XProc scenarios is the Calabash engine that comes bundled with Oxygen XML Editor version 19.1.

XProc Content Completion

Oxygen XML Editor helps you edit a XProc scripts through the *Content Completion Assistant*, offering proposals that are valid at the cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

The content completion inside the element `input/inline` from the XProc namespace *http://www.w3.org/ns/xproc* offers elements from the following schemas depending both on the `port` attribute and the parent of the `input` element. When invoking the content completion inside the XProc element `inline`, the list of content completion proposals is populated as follows:

- If the value of the `port` attribute is `stylesheet` and the `xslt` element is the parent of the `input` elements, the *Content Completion Assistant* offers XSLT elements.
- If the value of the `port` attribute is `schema` and the `validate-with-relax-ng` element is the parent of the `input` element, the *Content Completion Assistant* offers RELAX NG schema elements.
- If the value of the `port` attribute is `schema` and the `validate-with-xml-schema` element is the parent of the `input` element, the *Content Completion Assistant* offers XML Schema schema elements.
- If the value of the `port` attribute is `schema` and the `validate-with-schematron` element is the parent of the `input` element , the *Content Completion Assistant* offers either ISO Schematron elements or Schematron 1.5 schema elements.
- If the above cases do not apply, then the *Content Completion Assistant* offers elements from all the schemas from the above cases.

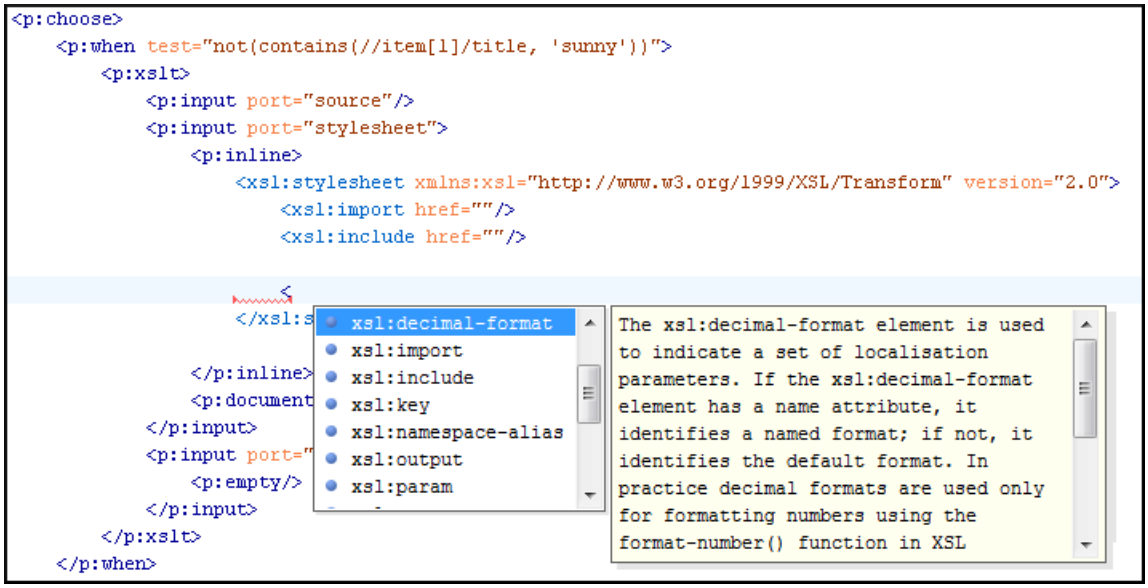

Figure 568: XProc Content Completion

XProc Syntax Highlighting

The XProc editor assists you in writing XPath expressions by offering dedicated coloring schemes for syntax highlighting.

To customize the colors or styles used for the syntax highlighting colors for XProc, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.
5. Select the **XML** tab in the **Preview** pane to see the effects of your changes.

Editing Schematron Schemas

Schematron is a simple and powerful Structural Schema Language for making assertions about patterns found in XML documents. It relies almost entirely on XPath query patterns for defining rules and checks. Schematron validation rules allow you to specify a meaningful error message. This error message is provided to you if an error is encountered during the validation stage.

Oxygen XML Editor assists you in editing Schematron documents with schema-based content completion, syntax highlight, search and refactor actions, and dedicated icons for the ***Outline** view*. You can create a new Schematron schema using one of the Schematron templates available in the ***New** document wizard*.

For information about applying and detecting Schematron schemas, see *Associating a Schema to XML Documents* on page 674.

Validating XML Documents Against Schematron

The Skeleton XSLT processor is used for validation and conforms with ISO Schematron or Schematron 1.5. It allows you to *validate XML documents against Schematron schemas* or against combined RELAX NG / W3C XML Schema and Schematron.

How to Specify the Query Language Binding

You can specify the query language binding to be used in the Schematron schema by doing the following:

- For embedded ISO schematron, *open the **Preferences** dialog box **(Options > Preferences)***, go to **XML** > **XML Parser** > **Schematron**, and select it in the ***Embedded rules query language binding** option*.
- For standalone ISO Schematron, specify the version by setting the query language to be used in a `queryBinding` attribute on the schema root element. For more information, see the *Query Language Binding section of the Schematron specifications*.
- For Schematron 1.5 (standalone and embedded), *open the **Preferences** dialog box **(Options > Preferences)***, go to **XML** > **XML Parser** > **Schematron**, and select the version in the ***XPath Version** option*.

Multi-Lingual Support in Schematron Messages

You can specify the desired language for the validation messages in *the **Schematron Preferences** page*. The Schematron validation messages can be presented in multiple languages by defining the language for each message using the Schematron `diagnostics`. For more information, see the *Use of Schematron for Multi-Lingual Schemas* specification.

How to Customize Color Schemes in Schematron

The Schematron editor renders the XPath expressions with dedicated coloring schemes . To customize the coloring schemes, *open the **Preferences** dialog box **(Options > Preferences)*** and go to **Editor** > **Syntax Highlight**.

Schematron Transformation Scenario

When you create a Schematron document, Oxygen XML Editor provides a built-in transformation scenario. You can use this scenario to obtain the XSLT style-sheet corresponding to the Schematron schema. You can apply this XSLT stylesheet to XML documents to obtain the Schematron validation results.

For more information about the Schematron support in Oxygen XML Editor, watch our video demonstrations:

Related Information:

Editing XML Documents in Text Mode on page 492
Associating a Schema to XML Documents on page 674

Editing Schematron Schema in the Master Files Context

Smaller interrelated modules that define a complex Schematron cannot be correctly edited or validated individually, due to their interdependency with other modules. For example, a diagnostic defined in a main schema document is not visible when you edit an included module. Oxygen XML Editor provides the support for defining the main module (or modules), thus allowing you to edit any of the imported/included schema files in the context of the larger schema structure.

You cat set a main Schematron document either using the *master files support from the **Project** view*, or using a validation scenario.

To set a main file using a validation scenario, add validation units that point to the main schemas. Oxygen XML Editor warns you if the current module is not part of the dependencies graph computed for the main schema. In this case, it considers the current module as the main schema.

The advantages of editing in the context of main file include:

- Correct validation of a module in the context of a larger schema structure.
- *Content Completion Assistant* displays all the referable components valid in the current context. This include components defined in modules other than the currently edited one.

Validating Schematron Documents

By default, a Schematron schema is validated as you type. To change this, *open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Editor** > **Document Checking**, and deselect the ***Enable automatic validation*** *option*.

To validate a Schematron document manually, select the **Validate** action from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu. When Oxygen XML Editor validates a Schematron schema, it expands all the included modules so the entire schema hierarchy is validated. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Oxygen XML Editor offers an error management mechanism capable of pinpointing errors in XPath expressions and in the included schema modules.

Related Information:

Presenting Schematron Validation Issues

Presenting Schematron Validation Issues

The possible issues that might occur during the validation process when validating XML documents against Schematron are presented with colored underlines in the editing pane, colored markers in the right vertical stripe, and details about the issues are presented in the **Errors** panel at the bottom area of the Oxygen XML Editor window. Each error is flagged with a severity level that can be: *warning*, *error*, *fatal* or *info*.

To set a severity level, Oxygen XML Editor looks for the following information:

- The **role** attribute, which can have one of the following values:
  - **warn** or **warning** - Sets the severity level to *warning*. By default, underlined with a yellow squiggly line in the editing pane and a yellow marker in the right vertical stripe.
  - **error** - Sets the severity level to *error*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - **fatal** - Sets the severity level to *fatal*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - **info** or **information** - Sets the severity level to *info*. By default, underlined with a blue squiggly line in the editing pane and a blue marker in the right vertical stripe.
- The start of the message, after trimming leading white-spaces. Oxygen XML Editor looks to match the following exact string of characters (case sensitive):
  - **Warning:** - Sets the severity level to *warning*. By default, underlined with a yellow squiggly line in the editing pane and a yellow marker in the right vertical stripe.
  - **Error:** - Sets the severity level to *error*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - **Fatal:** - Sets the severity level to *fatal*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.
  - **Info:** - Sets the severity level to *info*. By default, underlined with a blue squiggly line in the editing pane and a blue marker in the right vertical stripe.
- If none of the previous rules match, Oxygen XML Editor sets the severity level to *error*. By default, underlined with a red squiggly line in the editing pane and a red marker in the right vertical stripe.

Tip: You can configure the color for each type in the ***Document Checking*** *preferences page*.

Presenting Validation Errors in Text Mode on page 227

Content Completion in Schematron Documents

Oxygen XML Editor helps you edit a Schematron schema through the *Content Completion Assistant*, offering proposals that are valid at the cursor position. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

When you edit the value of an attribute that refers a component, the proposed components are collected from the entire schema hierarchy. For example, if the editing context is `phase/active/@pattern`, the *Content Completion Assistant* proposes all the defined patterns.

Note: For Schematron resources, the *Content Completion Assistant* collects its components starting from the *master files*. The *master files* can be defined in the project or in the associated validation scenario. For further details about the *Master Files* support go to *Defining Master Files at Project Level*.

If the editing context is an attribute value that is an XPath expression (such as `assert/@test` or `report/@test`), the *Content Completion Assistant* offers the names of XPath functions, the XPath axes, and user-defined variables.

The *Content Completion Assistant* displays XSLT 1.0 functions and optionally XSLT 2.0 / 3.0 functions in the attributes *path*, *select*, *context*, *subject*, *test* depending on *the Schematron options* that are set in Preferences pages. If the Saxon 6.5.5 namespace (`xmlns:saxon="http://icl.com/saxon"`) or the Saxon 9.7.0.19 namespace is declared in the Schematron schema (`xmlns:saxon="http://saxon.sf.net/"`) the content completion also displays the XSLT Saxon extension functions as in the following figure:

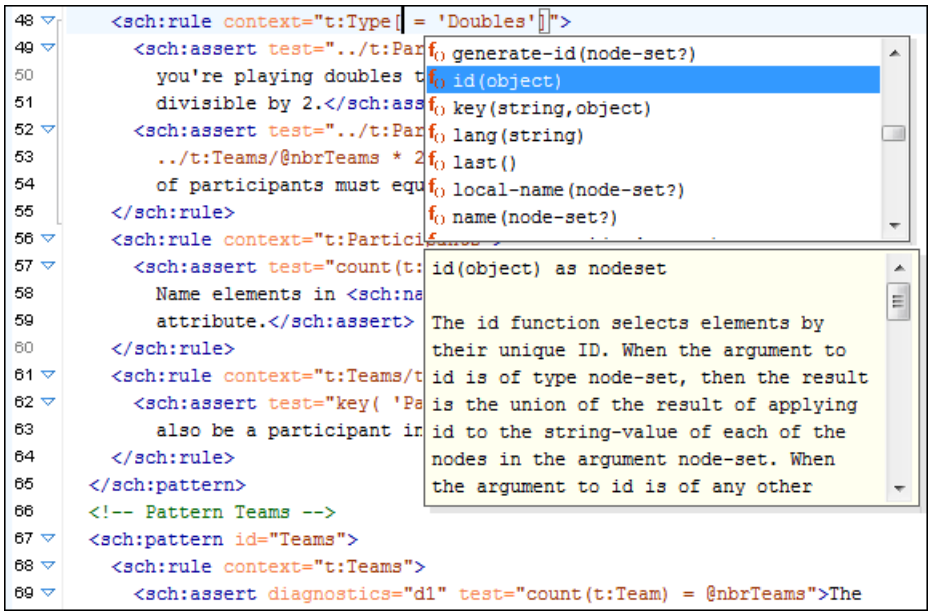

Figure 569: XSLT Extension Functions in Schematron Schema Content Completion

The *Content Completion Assistant* also includes *code templates that can be used to quickly insert code fragments* into Schematron documents.

Syntax Highlighting in Schematron

Oxygen XML Editor supports syntax highlighting in Schematron schemas to improve the readability of the content and reduce the time it takes to internalize the semantics of the structured content.

To customize the colors or styles used for the syntax highlighting colors for Schematron schemas, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor > Syntax Highlight***.
3. Select and expand the **XML** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

5. Select the **XML** tab in the **Preview** pane to see the effects of your changes.

Tip: Oxygen XML Editor also allows you to specify syntax highlighting colors for specific XML elements and attributes with specific namespace prefixes. This can be done in the ***Editor*** > ***Syntax Highlight*** > ***Elements/ Attributes by Prefix*** *preferences page*.

Related Information:

Syntax Highlight Preferences on page 105

XML Schema or RELAX NG with Embedded Schematron Rules

Schematron rules can be embedded into an XML Schema through annotations (using the `appinfo` element), or in any element on any level of a RELAX NG Schema (taking into account that the RELAX NG validator ignores all elements that are not in the RELAX NG namespace).

Oxygen XML Editor accepts such documents as Schematron validation schemas and it is able to extract and use the embedded rules.

Validating XML Documents with XML Schema and Embedded Schematron

To validate an XML document with XML Schema and its embedded Schematron, you can associate the document like this:

```
<?xml-model href="percent.xsd" type="application/xml"
            schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

Validating XML Documents with Relax NG and Embedded Schematron

To validate an XML document with RELAX NG schema and its embedded Schematron rules, you need to associate the document with both schemas like this:

```
<?xml-model href="percent.rng" type="application/xml"
            schematypens="http://relaxng.org/ns/structure/1.0"?>
<?xml-model href="percent.rng" type="application/xml"
            schematypens="http://purl.oclc.org/dsdl/schematron"?>
```

The second association validates your document with Schematron rules extracted from the RELAX NG Schema.

Note: When you work with XML Schema or Relax NG documents that have embedded Schematron rules Oxygen XML Editor provides two built-in validation scenarios: **Validate XML Schema with embedded Schematron** for XML schema , and **Validate Relax NG with embedded Schematron** for Relax NG. You can use one of these scenarios to validate the embedded Schematron rules.

Example: Embedded Schematron in XML Schema

```
<xsd:appinfo>
  <sch:pattern>
    <sch:rule context="...">
 <sch:assert test="...">Message.</sch:assert>
    </sch:rule>
  </sch:pattern>
</xsd:appinfo>
```

Example: Embedded Schematron in Relax NG Schema

```
<grammar
    xmlns="http://relaxng.org/ns/structure/1.0"
    xmlns:sch="http://purl.oclc.org/dsdl/schematron" >
    <sch:pattern>
      <sch:rule context="...">
        <sch:assert test="...">Message.</sch:assert>
      </sch:rule>
    </sch:pattern>
    <start>
     ..............
    </start>
</grammar>
```

Embed Schematron Quick Fixes in Relax NG or XML Schema on page 916

Schematron Outline View

The **Outline** view for Schematron schemas presents a list of components in a tree-like structure and it allows for quick access to a component by name. By default, it is displayed on the left side of the editor. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

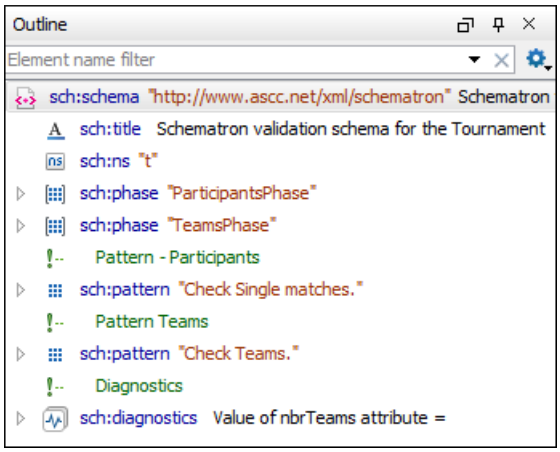

Figure 570: Schematron Outline View

The following actions are available in the **Settings** menu on the **Outline** view toolbar:

Filter returns exact matches

The text filter of the **Outline** view returns only exact matches.

Selection update on cursor move

Controls the synchronization between **Outline** view and source document. The selection in the **Outline** view can be synchronized with the cursor moves or the changes in the editor. Selecting one of the components from the **Outline** view also selects the corresponding item in the source document.

Flat presentation mode of the filtered results

When active, the application flattens the filtered result elements to a single level.

Show comments and processing instructions

Show/hide comments and processing instructions in the **Outline** view.

Show element name

Show/hide element name.

Show text

Show/hide additional text content for the displayed elements.

Show attributes

Show/hide attribute values for the displayed elements. The displayed attribute values can be changed from *the Outline preferences panel*.

Configure displayed attributes

Displays the *XML Structured Outline preferences page*.

The following contextual menu actions are also available in the **Outline** view:

Append Child

Displays a list of elements that you can insert as children of the current element.

Insert Before

Displays a list of elements that you can insert as siblings of the current element, before the current element.

Insert After

Displays a list of elements that you can insert as siblings of the current element, after the current element.

Edit Attributes

Opens a dialog box that allows you to edit the attributes of the currently selected component.

Toggle Comment

Comments/uncomments the currently selected element.

Cut

Cuts the currently selected component.

Copy

Copies the currently selected component.

Delete

Deletes the currently selected component.

Expand More

Expands the structure of a component in the **Outline** view.

Collapse All

Collapses the structure of all the component in the **Outline** view.

The upper part of the **Outline** view contains a filter box that allows you to focus on the relevant components. Type a text fragment in the filter box and only the components that match it are presented. For advanced usage you can use wildcard characters (*, ?) and separate multiple patterns with commas.

Schematron Resource Hierarchy/Dependencies View

The **Resource Hierarchy/Dependencies** view allows you to see the hierarchy/dependencies for a Schematron schema. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

If you want to see the hierarchy of a schema, select the desired schema in the ***Project*** *view* and choose **Resource Hierarchy** from the contextual menu.

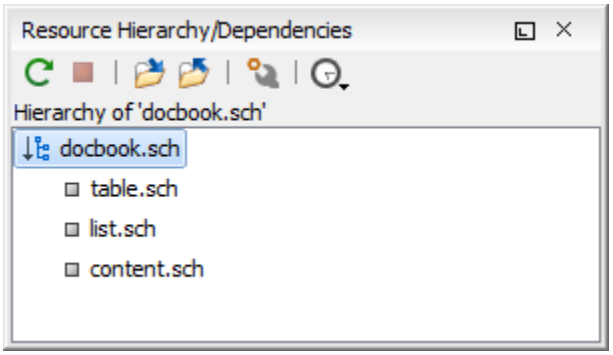

Figure 571: Resource Hierarchy/Dependencies View

If you want to see the dependencies of a schema, select the desired schema in the ***Project*** *view* and choose **Resource Dependencies** from the contextual menu.

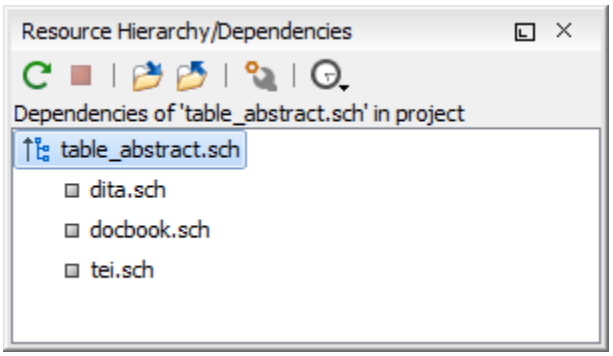

Figure 572: Resource Hierarchy/Dependencies View - Dependencies for `table_abstract.sch`

The following actions are available in the **Resource Hierarchy/Dependencies** view:

Refresh

Refreshes the Hierarchy/Dependencies structure.

Stop

Stops the hierarchy/dependencies computing.

Show Hierarchy

Allows you to choose a resource to compute the hierarchy structure.

Show Dependencies

Allows you to choose a resource to compute the dependencies structure.

Configure

Allows you to configure a scope to compute the dependencies structure. There is also an option for automatically using the defined scope for future operations.

History

Provides access to the list of previously computed dependencies. Use the **Clear history** button to remove all items from this list.

The contextual menu contains the following actions:

Open

Opens the resource. You can also double-click a resource in the Hierarchy/Dependencies structure to open it.

Copy location

Copies the location of the resource.

Move resource

Moves the selected resource.

Rename resource

Renames the selected resource.

Show Resource Hierarchy

Shows the hierarchy for the selected resource.

Show Resource Dependencies

Shows the dependencies for the selected resource.

Add to Master Files

Adds the currently selected resource in *the **Master Files** directory*.

Expand All

Expands all the children of the selected resource from the Hierarchy/Dependencies structure.

Collapse All

Collapses all children of the selected resource from the Hierarchy/Dependencies structure.

Tip: When a recursive reference is encountered in the Hierarchy view, the reference is marked with a special icon .

Note: The **Move resource** or **Rename resource** actions give you the option to *update the references to the resource*.

Moving/Renaming Schematron Resources

You can move and rename a resource presented in the **Resource/Hierarchy Dependencies** view, using the **Rename resource** and **Move resource** refactoring actions from the contextual menu.

When you select the **Rename** action in the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Rename resource** dialog box is displayed. The following fields are available:

- **New name** - Presents the current name of the edited resource and allows you to modify it.
- **Update references** - Select this option to update the references to the resource you are renaming.

When you select the **Move** action from the contextual menu of the **Resource/Hierarchy Dependencies** view, the **Move resource** dialog box is displayed. The following fields are available:

- **Destination** - Presents the path to the current location of the resource you want to move and gives you the option to introduce a new location.
- **New name** - Presents the current name of the moved resource and gives you the option to change it.
- **Update references of the moved resource(s)** - Select this option to update the references to the resource you are moving, in accordance with the new location and name.

If the **Update references of the moved resource(s)** option is selected, a **Preview** option (which opens the **Preview** dialog box) is available for both actions. The **Preview** dialog box presents a list with the resources that are updated.

Highlight Component Occurrences in Schematron Documents

When you position your mouse cursor over a component in a Schematron document, Oxygen XML Editor searches for the component declaration and all its references and highlights them automatically.

Customizable colors are used: one for the component definition and another one for component references. Occurrences are displayed until another component is selected.

To change the default behavior of **Highlight Component Occurrences**, *open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Editor** > **Mark Occurrences**. You can also trigger a search using the **Search** > **Search Occurrences in File** **Ctrl + Shift + U (Command + Shift + U on OS X)** action from contextual menu. Matches are displayed in separate tabs of the ***Results*** *view*.

Searching and Refactoring Operations in Schematron Documents

Search Actions

The following search actions can be applied on `pattern`, `phase`, or `diagnostic` types and are available from the **Search** submenu in the contextual menu of the current editor or from the **Document** > **References** menu:

- **Search References** - Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.
- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.

- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

Refactoring Actions

The following refactoring actions can be applied on `pattern`, `phase`, or `diagnostic` types and are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document** > **Refactoring** menu:

- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.
- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

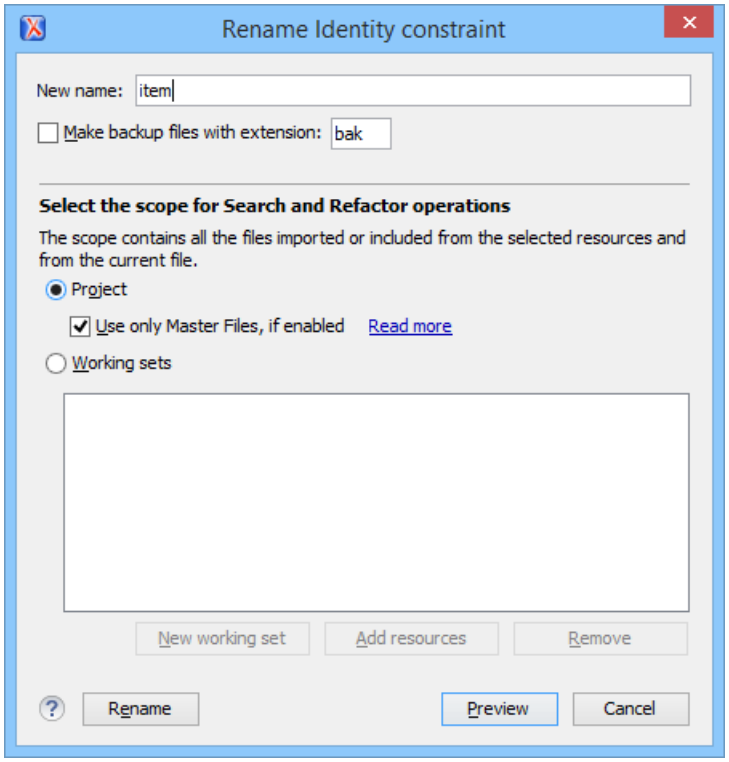

Figure 573: Rename Identity Constraint Dialog Box

Searching and Refactoring Operations Scope in Schematron Documents

The *scope* is a collection of documents that define the context of a search and refactor operation. To control it you can use the **Change scope** operation, available in the *Quick Assist* action set or on the **Resource Hierarchy/Dependency View** toolbar. You can restrict the scope to the current project or to one or multiple *working sets*. The **Use only Master Files, if enabled** checkbox allows you to restrict the scope of the search and refactor operations to the resources from the **Master Files** directory. Click **read more** for details about the *Master Files support*.

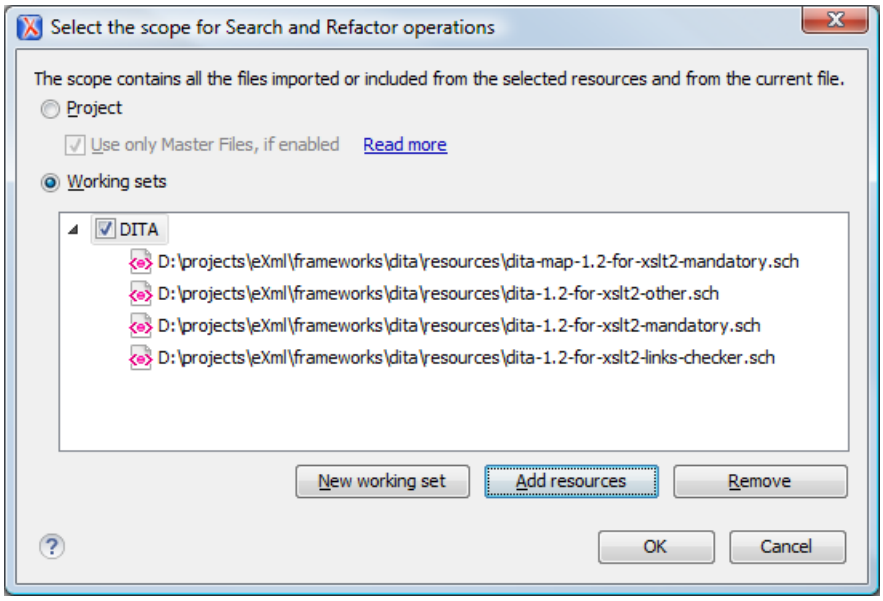

Figure 574: Change Scope Dialog Box

The scope you define is applied to all future search and refactor operations until you modify it. Contextual menu actions allow you to add or delete files, folders, and other resources to the *working set* structure.

Quick Assist Support in Schematron Documents

The *Quick Assist support* improves the development work flow, offering fast access to the most commonly used actions when you edit schema documents.

The *Quick Assist feature* is activated automatically when the cursor is positioned over the name of a component. It is accessible via a yellow bulb icon ( ) placed at the current line in the stripe on the left side of the editor. Also, you can invoke the *quick assist* menu by using the **Alt + 1** (**Meta + Alt + 1** on Mac OS X) keyboard shortcuts.

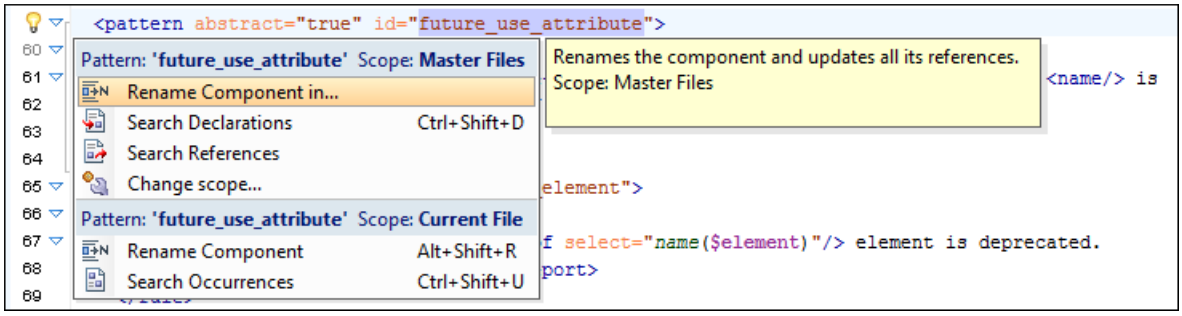

Figure 575: Schematron Quick Assist Support

The *Quick Assist* support offers direct access to the following actions:

Rename Component in

Renames the component and all its dependencies.

Search Declarations

Searches the declaration of the component in a predefined scope. It is available only when the context represents a component name reference.

Search References

Searches all references of the component in a predefined scope.

Component Dependencies

Searches the component dependencies in a predefined scope.

Change Scope

Configures the scope that will be used for future search or refactor operations.

Rename Component

Allows you to rename the current component in-place.

Search Occurrences

Searches all occurrences of the component within the current file.

Editing Schematron Quick Fixes

Oxygen XML Editor provides support for editing the *Schematron Quick Fixes*. You can define a library of *Quick Fixes* by editing them directly in the current Schematron file or in a separate file. Oxygen XML Editor assists you in editing Schematron *Quick Fixes* with schema-based content completion, syntax highlighting, and validation as you type.

For information about applying and detecting the Schematron schemas that include SQF, see *Associating a Schema to XML Documents* on page 674.

Related Information:

Oxygen XML Blog: Schematron Checks to Help Technical Writing

Schematron Quick Fixes (SQF)

Oxygen XML Editor provides support for Schematron *Quick Fixes* (SQF). They help you resolve issues that appear in XML documents that are validated against Schematron schemas by offering you solution proposals. The Schematron *Quick Fixes* are an extension of the Schematron language and they allow you to define fixes for Schematron validation messages. Specifically, they are associated with *assert* or *report* messages.

A typical use case is using Schematron *Quick Fixes* to assist content authors with common editing tasks. For example, you can use Schematron rules to automatically report certain validation warnings (or errors) when performing regular editing tasks, such as inserting specific elements or changing IDs to match specific naming conventions. For more details and examples, please see the following blog post: *http://blog.oxygenxml.com/2015/05/schematron-checks-to-help-technical.html*.

Displaying the Schematron Quick Fix Proposals

The defined Schematron *Quick Fixes* are displayed on validation errors in **Text** mode and **Author** mode.

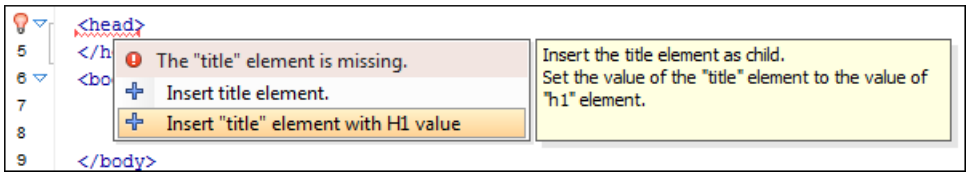

Figure 576: Example of a Schematron Quick Fix

Schematron Quick Fix Specifications

Presenting Schematron Validation Issues

Defining Schematron Quick Fixes

You can define and customize Schematron *Quick Fixes* directly in the current Schematron file or in a separate Schematron file. The Schematron *Quick Fixes* are an extension of the Schematron language and they allow you to define fixes for Schematron error messages. You can refer the *Quick Fixes* from the `assert` or `report` elements in the values of the `sqf:fix` attributes.

Defining a Schematron Quick Fix

The basics of a Schematron *Quick Fix* is defined by an ID, name, description, and the operations to be executed.

- **ID** - Defined by the `id` attribute from the `fix` element and must be unique in the current context. It is used to refer the *Quick Fix* from a `report` or `assert` element.
- **Name** - The name of the *Quick Fix* is defined by the `title` element.
- **Description** - Defined by the text in the paragraphs (p) of the `description` element.
- **Operations** - The following basic types of *operations (elements)* are supported:
  - `<sqf:add>` Element - To add a new node or fragment in the document.
  - `<sqf:delete>` Element - To remove a node from the document.
  - `<sqf:replace>` Element - To replace a node with another node or fragment.
  - `<sqf:stringReplace>` Element - To replace text content with other text or a fragment.

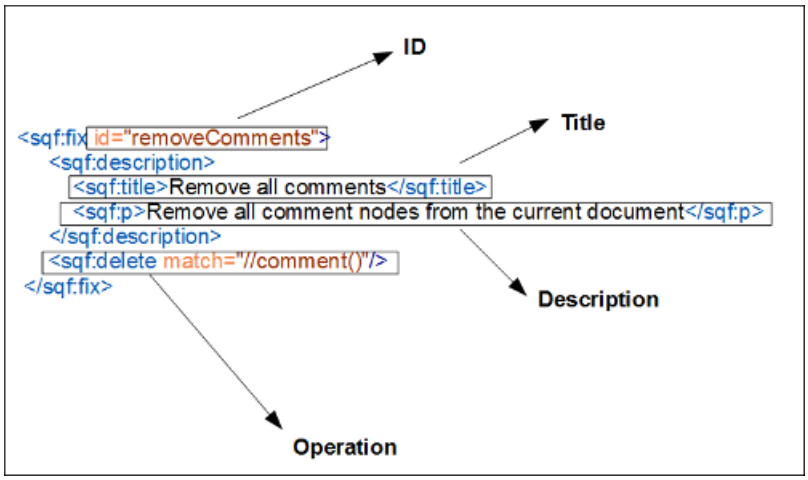

Figure 577: Schematron Quick Fix Components

The assertion message that generates the *Quick Fix* is added as the `description` of the problem to be fixed. The `title` is presented as the name of the *Quick Fix*. The content of the paragraphs (p) within the `description` element are presented in the tooltip message when the *Quick Fix* is selected.

Additional Elements Supported in the Schematron Quick Fixes

`<sqf:user-entry>`

This element defines a value that must be set manually by the user. For more information, see *User Entry SQF Operation* on page 913.

`<sqf:call-fix>`

This element calls another *Quick Fix* within a *Quick Fix*. The called *Quick Fix* must be defined globally or in the same Schematron rule as the calling *Quick Fix*. A calling *Quick Fix* adopts the activity elements of the called *Quick Fix* and should not include other activity elements. You can also specify which parameters are sent by using the `<sqf:with-param>` child element.

`<sqf:group>`

Allows you to group multiple *Quick Fixes* and refer them from an `assert` or `report` element.

`<sqf:fixes>`

Is defined globally and contains global fixes and groups of fixes.

`<sqf:keep>`

Used to copy the selected nodes that are specified by the `select` attribute.

Note: In Oxygen XML Editor the copied nodes cannot be manipulated by the current or other activity elements.

<sqf:param>

Defines a parameter for a *Quick Fix*. If the parameter is defined as `abstract` then the `type` and default value should not be specified and the fix can be called from an abstract pattern that defines this parameter.

Other SQF Notes

Note: The `sqf:default-fix` attribute is ignored in Oxygen XML Editor.

For more details on editing Schematron *Quick Fixes*, go to: *Schematron Quick Fix Specifications*

Basic Schematron Quick Fix Operations

There are four basic operations that can be executed in a Schematron *Quick Fix*: **Add**, **Delete**, **Replace**, and **String Replace**.

Add

The `<sqf:add>` element allows you to add a node to the instance. An *anchor* node is required to select the position for the new node. The *anchor* node can be selected by the `match` attribute. Otherwise, it is selected by the `context` attribute of the rule.

The `target` attribute defines the name of the node to be added. It is required if the value of the `node-type` attribute is set to anything other than "comment".

The `<sqf:add>` element has a `position` attribute and it determines the position relative to the *anchor* node. The new node could be specified as the first child of the *anchor* node, the last child of the *anchor* node, before the *anchor* node, or after the *anchor* node (`first-child` is the default value). If you want to add an attribute to the *anchor* node, do not use the `position` attribute.

Note: If you insert an element and its content is empty, Oxygen XML Editor will insert the required element content.

An Example of the <sqf:add> Element:

```
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
   xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
 queryBinding="xslt2">
   <pattern>
     <rule context="head">
        <assert test="title" sqf:fix="addTitle">title element missing.</assert>
        <sqf:fix id="addTitle">
            <sqf:description>
                <sqf:title>Insert title element.</sqf:title>
            </sqf:description>
           <sqf:add target="title" node-type="element">Title text</sqf:add>
        </sqf:fix>
     </rule>
   </pattern>
</schema>
```

Specific Add Operations:

- **Insert Element** - To insert an element, use the `<sqf:add>` element, set the value of the `node-type` to "element", and specify the element *QName* with the `target` attribute. If the element has a prefix, it must be defined in the Schematron using a namespace declaration (`<ns uri="namespace" prefix="prefix"/>`).
- **Insert Attribute** - To insert an attribute, use the `<sqf:add>` element, set the value of the `node-type` to "attribute", and specify the attribute *QName* with the `target` attribute. If the attribute has a prefix, it must be defined in the Schematron using a namespace declaration (`<ns uri="namespace" prefix="prefix"/>`).
- **Insert Fragment** - If the `node-type` is not specified, the `<sqf:add>` element will insert an XML fragment. The XML fragment must be well formed. You can specify the fragment in the `add` element or by using the `select` attribute.
- **Insert Comment** - To insert a comment, use the `<sqf:add>` element and set the value of the `node-type` to "comment".
- **Insert Processing Instruction** - To insert a processing instruction, use the `<sqf:add>` element, set the value of the `node-type` to "pi" or "processing-instruction", and specify the name of the processing instruction in the `target` attribute.

Delete

The `<sqf:delete>` element allows you to remove any type of node (such as elements, attributes, text, comments, or processing instructions). To specify nodes for deletion the `<sqf:delete>` element can include a `match` attribute that is an XPath expression (the default value is `.`). If the `match` attribute is not included, it deletes the context node of the Schematron rule.

An Example of the `<sqf:delete>` Element:

```
<schema xmlns="http://purl.oclc.org/dsdl/schematron" queryBinding="xslt2"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process">
    <pattern>
        <rule context="*[@xml:lang]">
            <report test="@xml:lang" sqf:fix="remove_lang">
                The attribute "xml:lang" is forbidden.</report>
            <sqf:fix id="remove_lang">
                <sqf:description>
                    <sqf:title>Remove "xml:lang" attribute</sqf:title>
                </sqf:description>
                <sqf:delete match="@xml:lang"/>
            </sqf:fix>
        </rule>
    </pattern>
</schema>
```

Replace

The `<sqf:replace>` element allows you to replace nodes. Similar to the `<sqf:delete>` element, it can include a `match` attribute. Otherwise, it replaces the context node of the rule. The `<sqf:replace>` element has three tasks. It identifies the nodes to be replaced, defines the replacing nodes, and defines their content.

An Example of the `<sqf:replace>` Element:

```
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
 queryBinding="xslt2">
    <pattern>
        <rule context="title">
            <report test="exists(ph)" sqf:fix="resolvePh" role="warn">
                ph element is not allowed in title.</report>
            <sqf:fix id="resolvePh">
                <sqf:description>
                    <sqf:title>Change the ph element into text</sqf:title>
                </sqf:description>
                <sqf:replace match="ph">
                    <value-of select="."/>
                </sqf:replace>
            </sqf:fix>
        </rule>
    </pattern>
</schema>
```

Other Attributes for Replace Operations:

- **`node-type`** - Determines the type of the replacing node. The permitted values include:
  - `keep` - Keeps the node type of the node to be replaced.
  - `element` - Replaces the node with an element.
  - `attribute` - Replaces the node with an attribute.
  - `pi` - Replaces the node with a processing instruction.
  - `comment` - Replaces the node with a comment.
- **`target`** - By using a *QName* it gives the replacing node a name. This is necessary when the value of the `node-type` attribute is anything other than "comment".
- **`select`** - Allows you to choose the content of the replacing nodes. You can use XPath expressions with the `select` attribute. If the `select` attribute is not specified then the content of the `<sqf:replace>` element is used instead.

String Replace

The `<sqf:stringReplace>` element is different from the others. It can be used to find a sub-string of text content and replace it with nodes or other strings.

Attributes for the String Replace Operation:

- **`match`** - Allows you to select text nodes that contain the sub-strings you want to replace.

- **`select`** - Allows you to select the replacing fragment, in case you do not want to set it in the content of the `stringReplace` element.
- **`regex`** - Matches the sub-strings using a regular expression.

  Note: Consider the following information about using regular expressions in the `stringReplace` element:

  - The regular expressions from this operation are compiled as Java regular expressions. For more information, see *https://docs.oracle.com/javase/7/docs/api/java/util/regex/Pattern.html*.
  - The ***j flag*** allows you to use the standard Java regular expression engine, which allows native Java regular expression syntax. This allows, for example, the use of **`\b`** in a regular expression to match word boundaries. For more information, see *http://www.saxonica.com/html/documentation/functions/fn/matches.html*.
  - Regular expressions in the `<sqf:stringReplace>` element always have the *dot matches all* flag set to "true". Therefore, the line terminator will also be matched by the regular expression.

Attention: The context of the content within the `<sqf:stringReplace>` element is set to the whole text node, rather than the current sub-string.

An Example of the `<sqf:stringReplace>` Element:

```
<?xml version="1.0" encoding="UTF-8"?>
<sch:schema xmlns:sch="http://purl.oclc.org/dsdl/schematron"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
 queryBinding="xslt2">
    <sch:pattern>
        <sch:rule context="text()">
            <sch:report test="matches(., '[oO][xX]ygen')"
 sqf:fix="changeWord">The oXygen word is not allowed</sch:report>
            <sqf:fix id="changeWord">
                <sqf:description>
                    <sqf:title>Replace word with product</sqf:title>
                </sqf:description>
                <sqf:stringReplace regex="[oO][xX]ygen"><ph keyref="product"/>
                </sqf:stringReplace>
            </sqf:fix>
        </sch:rule>
    </sch:pattern>
</sch:schema>
```

Related Information:

User Entry SQF Operation on page 913
Restricting Quick Fix Operations on page 913

User Entry SQF Operation

The `<sqf:user-entry>` element defines a value that must be set manually by the user. If multiple `user-entry` elements are defined, Oxygen XML Editor will display a dialog box for each one, in which the user can specify values. Also, the `<user-entry>` element can be used as an XPath variable where the XPath variable is the name of the `user-entry`. Note that the `default` attribute defines a default value for the operation by using an XPath expression (as in the example below) and its value will be presented in the user entry dialog box.

An Example of the `<sqf:user-entry>` Element:

```
<sqf:fix id="editTitle">
    <sqf:description>
        <sqf:title>Edit the jurnal title</sqf:title>
    </sqf:description>
    <sqf:user-entry name="newTitle" default="@title">
        <sqf:description>
            <sqf:title>Edit the title:</sqf:title>
        </sqf:description>
    </sqf:user-entry>
    <sqf:replace match="@title" target="title" node-type="keep" select="$newTitle"/>
</sqf:fix>
```

Related Information:

Basic Schematron Quick Fix Operations on page 911

Restricting Quick Fix Operations

To restrict a *Quick Fix* or a specific operation to only be available if certain conditions are met, the `use-when` attribute can be included in the `<sqf:fix>` element or any of the SQF operation elements. The condition of the

use-when attribute is an XPath expression and the fix or operation will be performed only if the condition is satisfied. In the following example, the use-when condition is applied to the <sqf:fix> element:

```
<sqf:fix id="last" use-when="$colWidthSummarized - 100 lt $lastWidth"
 role="replace">
   <sqf:description>
       <sqf:title>Subtract excessive width from the last element.</sqf:title>
   </sqf:description>
   <let name="delta" value="$colWidthSummarized - 100"/>
   <sqf:add match="html:col[last()]" target="width" node-type="attribute">
    <let name="newWidth" value="number(substring-before(@width,'%')) - $delta"/>
       <value-of select="concat($newWidth,'%')"/>
   </sqf:add>
</sqf:fix>
```

Related Information:

Basic Schematron Quick Fix Operations on page 911

Formatting/Indenting Content Inserted by SQF Operations

Content that is inserted by the **Add**, **Replace**, or **String Replace** Schematron *Quick Fix* operations is automatically indented unless you set the value of the xml:space attribute to preserve on the operation element. There are several methods available to format the content that is inserted:

- **xsl:text** - You can use an xsl:text element to format the inserted content and keep the automatic indentation, as in the following example:

  ```
  <sqf:add position="last-child">
      <row><xsl:text>
      </xsl:text>
          <entry>First column</entry><xsl:text>
          </xsl:text>
          <entry>Second column</entry><xsl:text>
          </xsl:text>
      </row><xsl:text>
      </xsl:text>
  </sqf:add>
  ```

- **xml:space** - Use the xml:space attribute and set its value to preserve to format the content and specify the spacing between elements, as in the following example:

  ```
  <sqf:add node-type="element" target="codeblock" xml:space="preserve">
      /* a long sample program */
      Do forever
       Say "Hello, World"
      End</sqf:add>
  ```

Related Information:

Basic Schematron Quick Fix Operations on page 911

Executing Schematron Quick Fixes in Other Documents

You can apply Schematron *Quick Fixes* over nodes from referenced documents (using XInclude or external entities), and you can access them as nodes in your current document.

Also, you can apply the *Quick Fixes* over other documents using the doc( ) function in the value of the match attribute. For example, you can add a new key in the keylist.xml file using the following operation:

```
<sqf:add match="doc('keylist.xml')/KeyList" target="Key"
 node-type="element" select="Key2">
```

Validating Schematron Quick Fixes

By default, Schematron *Quick Fixes* are validated as you edit them within the Schematron file or while editing them in a separate file. To change this, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Editor** > **Document Checking**, and deselect the ***Enable automatic validation** option*.

To validate Schematron *Quick Fixes* manually, select the **Validate** action from the **Validation** toolbar drop-down menu or the **Document** > **Validate** menu. The validation problems are highlighted directly in the editor, making it easy to locate and fix any issues.

Related Information:

Validating XML Documents Against a Schema on page 656

Validation Scenario on page 663

Presenting Validation Errors in Author Mode on page 280

Presenting Validation Errors in Text Mode on page 227

Content Completion in SQF

Oxygen XML Editor helps you edit Schematron *Quick Fixes* embedded in a Schematron document by offering proposals that are valid at the cursor position in a *Content Completion Assistant*. It can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut.

When you edit the value of an attribute that references a *Quick Fix ID*, the ids are collected from the entire definition scope. For example, if the editing context is `assert/@sqf:fix`, the *Content Completion Assistant* proposes all fixes defined locally and globally.

If the editing context is an attribute value that is an XPath expression (such as `sqf:add/@match` or `replace/@select`), the *Content Completion Assistant* offers the names of XPath functions, the XPath axes, and user-defined variables and parameters.

The *Content Completion Assistant* displays XSLT 1.0 functions (and optionally XSLT 2.0 / 3.0 functions) in the attributes *path*, *select*, *context*, *subject*, and *test*, depending on *the Schematron options* that are set in Preferences pages. If the Saxon 6.5.5 namespace (`xmlns:saxon="http://icl.com/saxon"`) or the Saxon 9.7.0.19 namespace is declared in the Schematron schema (`xmlns:saxon="http://saxon.sf.net/"`) the content completion also displays the XSLT Saxon extension functions.

Highlight Quick Fix Occurrences in SQF

When you position your mouse cursor over a *Quick Fix* ID in a Schematron document, Oxygen XML Editor searches for the *Quick Fix* declaration and all its references and highlights them automatically.

Customizable colors are used: one for the *Quick Fix* definition and another one for its references. Occurrences are displayed until another *Quick Fix* is selected.

To change the default behavior of **Highlight Component Occurrences**, *open the **Preferences** dialog box **(Options > Preferences)*** and go to **Editor** > **Mark Occurrences**. You can also trigger a search using the **Search** > **Search Occurrences in File (Ctrl + Shift + U (Command + Shift + U on OS X))** action from contextual menu. Matches are displayed in separate tabs of the ***Results** view*.

Searching and Refactoring Operations in SQF

Search Actions

The following search actions can be applied on *Quick Fix* IDs and are available from the **Search** submenu in the contextual menu of the current editor or from the **Document** > **References** menu:

- **Search References** - Searches all references of the item found at current cursor position in the defined scope, if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box is displayed and you have the possibility to define another search scope.
- **Search References in** - Searches all references of the item found at current cursor position in the file or files that you specify when define a scope in the **Search References** dialog box.
- **Search Declarations** - Searches all declarations of the item found at current cursor position in the defined scope if any. If a scope is defined, but the current edited resource is not part of the range of resources determined by this, a warning dialog box will be displayed and you have the possibility to define another search scope.
- **Search Declarations in** - Searches all declarations of the item found at current cursor position in the file or files that you specify when you define a scope for the search operation.
- **Search Occurrences in File** - Searches all occurrences of the item at the cursor position in the currently edited file.

Refactoring Actions

The following refactoring actions can be applied on *Quick Fix* IDs and are available from the **Refactoring** submenu in the contextual menu of the current editor or from the **Document** > **Refactoring** menu:

- **Rename Component** - Allows you to rename the current component (in-place). The component and all its references in the document are highlighted with a thin border and the changes you make to the component at the cursor position are updated in real time to all occurrences of the component. To exit the in-place editing, press the **Esc** or **Enter** key on your keyboard.
- **Rename Component in** - Opens a dialog box that allows you to rename the selected component by specifying the new component name and the files to be affected by the modification. If you click the **Preview** button, you can view the files to be affected by the action.

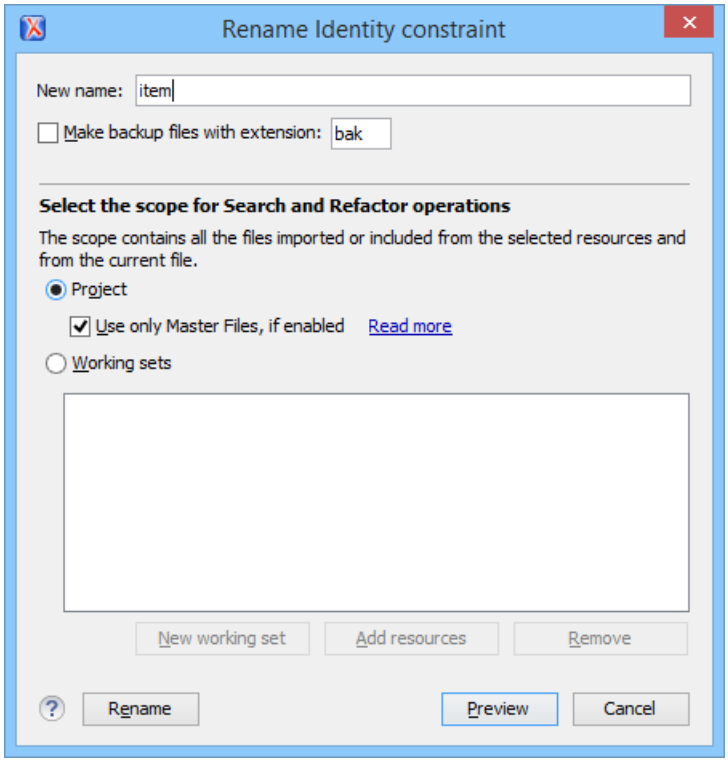

Figure 578: Rename Identity Constraint Dialog Box

Embed Schematron Quick Fixes in Relax NG or XML Schema

Schematron *Quick Fixes* can be embedded into an XML Schema through annotations (using the `appinfo` element), or in a schematron rule embedded in the RELAX NG Schema. For more information about embedding schematron in XML Schema or Relax NG, see *XML Schema or RELAX NG with Embedded Schematron Rules* on page 902.

Oxygen XML Editor is able to extract and use the embedded Schematron *Quick Fixes*. To make the embedded Schematron *Quick Fixes* available, follow these steps:

1. Define a *validation against a schema*.
2. For the **Schema type**, choose `XML Schema` or `Relax NG`.
3. Select the **Embedded schematron rules** option.

Example: Embedded Schematron Quick Fix in XML Schema

```
<xsd:appinfo>
  <sch:pattern>
    <sch:rule context="...">
 <sch:assert test="..." sqf:fix="fixId">Message.</sch:assert>
   <sqf:fix id="fixId">
     ......
   </sqf:fix>
    </sch:rule>
```

```
  </sch:pattern>
</xsd:appinfo>
```

Example: Embedded Schematron Quick Fix in Relax NG

```
<grammar
    xmlns="http://relaxng.org/ns/structure/1.0"
    xmlns:sch="http://purl.oclc.org/dsdl/schematron" >
    <sch:pattern>
      <sch:rule context="...">
        <sch:assert test="..." sqf:fix="fixId">Message.</sch:assert>
     <sqf:fix id="fixId">
       .....
     </sqf:fix>
      </sch:rule>
     </sch:pattern>
     <start>
      ..............
     </start>
</grammar>
```

Tip: For more extensive examples, see our samples in the *[OXYGEN_INSTALL_DIR]*`/samples/schematron` folder.

Defining Schematron Quick Fixes on page 909

Integrating SQF in a Framework

You can use Schematron *Quick Fixes* to assist your content authors by imposing rules for an entire *framework* (document type) and offering fixes when a rule violation is detected.

For example, if you are using DITA, you may want your contributors to avoid inserting a figure (`fig` element) inside a paragraph (p element) that contains other content since it may result in undesirable placement or spacing in the output. The Schematron rule and its *Quick Fix* for this particular use-case could look like this:

```
<schema xmlns="http://purl.oclc.org/dsdl/schematron"
    xmlns:sqf="http://www.schematron-quickfix.com/validator/process"
 queryBinding="xslt2">
   <pattern id="check.figure.location">
     <rule context="p/fig">
         <report test="true()" role="warn" sqf:fix="moveAfter">
         A figure inside a paragraph doesn't transform well into PDF. </report>
         <sqf:fix id="moveAfter">
             <sqf:description>
                 <sqf:title>Move after the paragraph.</sqf:title>
             </sqf:description>
             <let name="figToMove" value="."/>
             <sqf:add match="parent::p" select="$figToMove" position="after"/>
             <sqf:delete match="."/>
         </sqf:fix>
     </rule>
   </pattern>
</schema>
```

The result of this example would be that the user will see a warning if they insert a `fig` element inside a p element and they are presented with the option of selecting the *Quick Fix* that would move the figure outside the paragraph.

How to Integrate SQF in a Framework

To integrate a Schematron *Quick Fix* in a *framework*, follow these steps:

1. *Define a Schematron Quick Fix for a rule* in an existing or new Schematron file.
2. Save it somewhere in your *framework* directory. For example, the default *framework* directory for DITA is located in: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/`.
3. Add a reference to the Schematron file that includes the SQF in your *framework* by following the procedure in *Associating a Schema in Validation Scenarios Defined in the Document Type* on page 678.
4. Open a document in your *framework* and test the new rule and *Quick Fix*.
5. You can continue to refine the rule and develop additional rules as needed.

Editing SVG Files

SVG (Scalable Vector Graphics) is a platform for two-dimensional graphics. It has two parts: an XML-based file format and a programming API for graphical applications. Some of the key features include support for shapes, text, and embedded raster graphics with many painting styles, scripting through languages such as *ECMAScript*, and support for animation.

SVG is a vendor-neutral, open standard that has important industry support. Companies such as Adobe, Apple, and IBM have contributed to its W3C specifications. Many documentation *frameworks* (including DocBook) have support for SVG by defining the graphics directly in the document.

Oxygen XML Editor adds SVG support by using the *Batik distribution* package (an open source project developed by the Apache Software Foundation) and the *default XML Catalog* resolves the SVG DTD.

Note: Batik partially supports SVG 1.1. For a detailed list of supported elements, attributes, and properties, see the *Batik Implementation Status* page.

How to Render SVG Images that Use Java Scripting

1. Copy the `js.jar` library from the *Batik distribution* into the Oxygen XML Editor `lib` folder.
2. Restart the application.

SVG 1.2 Rendering Issues

Oxygen XML Editor uses the *Apache Batik* open source library to render SVG images and it only has partial support for SVG 1.2. For more information, see *http://xmlgraphics.apache.org/batik/dev/svg12.html*.

This partial support could lead to some rendering issues in Oxygen XML Editor. For example, if you are using the *Inkscape* SVG editor, it is possible for it to save the SVG as 1.1, while using SVG 1.2 elements (such as `flowRoot`) inside it. This means that the image will not be properly rendered inside the application.

Note: SVG images shown in the **Author** visual editing mode are rendered as static images, without support for animations and JavaScript.

Standalone SVG Viewer

Oxygen XML Editor includes a simple **SVG Viewer** that allows you to work with SVG images.

To open the viewer, select **SVG Viewer** from the **Tools** menu.

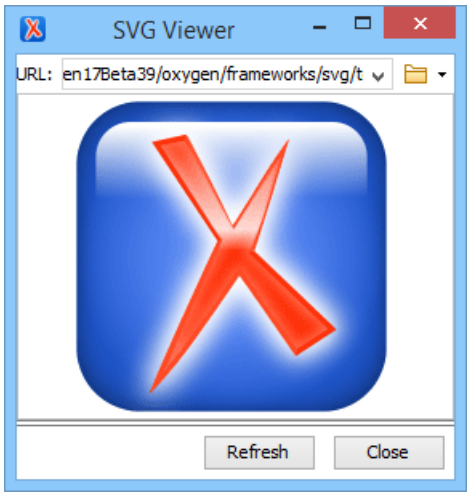

Figure 579: SVG Viewer

You can browse for and open any SVG file that has the `.svg` or `.svgz` extension.

If the file is included in the current project, you can open it in the viewer by right-clicking the image file in the ***Project*** *view* and selecting **Open with** > **SVG Viewer**.

Actions Available in the SVG Viewer

The following actions are available in the **SVG Viewer**:

Zoom in

To zoom in on an image, use any of the following methods:

- Scroll **forward** with the mouse wheel.
- Select **Zoom in** from the contextual menu.
- Use the **Ctrl + I (Command + I on OS X)** keyboard shortcut.

Zoom out

To zoom in on an image, use any of the following methods:

- Scroll **backward** with the mouse wheel.
- Use the **Ctrl + O (Command + O on OS X)** keyboard shortcut.
- Select **Zoom out** from the contextual menu.

Rotate

To rotate an image, use either of the following methods:

- Use the **Ctrl + Right-Click + Drag (Command + Right-Click + Drag on OS X)** shortcut.
- Select **Rotate** from the contextual menu. This rotates the image exactly 90 degrees clockwise.

Refresh

To refresh (or reset) an image, use either of the following methods:

- Use the **Ctrl + T (Command + T on OS X)** keyboard shortcut.
- Select **Refresh** from the contextual menu.

Move

To move an image, use either of the following methods:

- Use the **Arrow Keys** on your keyboard.
- Use the **Shift + Left-Click + Drag** shortcut.

Pan

To pan an image, **click and drag** the image with your mouse.

Related Information:
Editing SVG Files on page 918

Integrated SVG Viewer in the Results Panel

Oxygen XML Editor includes an integrated **SVG Viewer** that can render the results of an XSLT transformation scenario that generates SVG images in the ***Results*** *panel* at the bottom of the editor. This is useful for developing XSL stylesheets with the capability of producing SVG graphics.

To enable this feature, select **Show in results view as** > **SVG** in the ***Output*** *tab of the XSLT transformation scenario configuration dialog box*. When you run the transformation, the SVG result is then rendered in an integrated SVG viewer in the ***Results*** *panel*.

Example of a Use-Case

Suppose you have an XML document that describes the evolution of your sales over a time period and you want to create a graphic for it. You could use the following steps to accomplish this task:

1. Start with a static SVG image, written directly in Oxygen XML Editor or exported from a external graphics tool.
2. Extract the parts that are dependent upon the data from the XML document and create an XSL template to produce the image.
3. Create an ***XML transformation with XSLT*** *scenario*.
4. While configuring the transformation scenario, select ***Show in results view as*** > ***SVG*** *in the* ***Output*** *tab* of the configuration dialog box.
5. Run the transformation.

The SVG image is rendered in an integrated SVG viewer in the ***Results*** *panel* at the bottom of the editor.

Figure 580: Integrated SVG Viewer

Editing XHTML Documents

Oxygen XML Editor provides support for editing XHTML files. Oxygen XML Editor includes XHTML catalogs and document templates to help you get started. You can also find a sample file in the *[OXYGEN_INSTALL_DIR]*`/samples/xhtml` folder.

The XHTML editing features include:

- **Source Editing** - You can edit XHTML files in the ***Text*** *editing mode* (XML source editor) using all of its *useful features*.
- **Visual Editing** - You can edit XHTML files in the *visual* ***Author*** *editing mode* using all of its *authoring features*.
- **Validation** - Easily identify errors and their location with the Oxygen XML Editor *XML validation features*.
- **Content Completion** - The *Content Completion Assistant* displays a list of context-sensitive proposals that are valid at the current cursor position. In **Text** mode, it can be manually activated with the **Ctrl + Space (Command + Space on OS X)** shortcut, while in **Author** mode, it is activated by simply pressing **Enter**.

- **Import HTML as XHTML** - Oxygen XML Editor includes support for *importing HTML files as an XML document*.
- **Remote Editing** - Oxygen XML Editor has built-in support for *editing documents that are stored on remote servers through FTP, SFTP, and WebDAV protocols*, allowing you to edit XHTML pages from your web server.
- **Syntax Highlighting** - XHTML documents with embedded CSS, JS, PHP, and JSP scripts are rendered with dedicated coloring schemes. To customize them, *open the **Preferences** dialog box **(Options > Preferences)*** and go to ***Editor > Syntax Highlight***. Select and expand the **XHTML** section in the top pane and you can see the effects of your changes in the **Preview** pane.

XHTML Document Type (Framework) on page 1042

Editing Markdown Documents

Markdown was created as a lightweight markup language with plain text formatting syntax designed to provide a syntax that is very easy to read and write, and to convert it to HTML and other formats. It is often used by content contributors who want a quick and easy way to write content without having to take their fingers off the keyboard and without having to learn numerous codes or shortcuts, and it can easily be shared interchangeably between virtually any types of contributor and system.

Oxygen XML Editor provides a built-in Markdown editor that allows you to convert Markdown syntax to HTML or DITA and it includes a preview panel to help you visualize the final output. Aside from the plain text syntax that is common amongst most Markdown applications, the editor in Oxygen XML Editor also integrates many other powerful features that content authors are accustomed to using for other types of documents. Some of these additional unique features include:

- Additional toolbar and contextual menu actions.
- Automatic validation to help keep the syntax valid.
- Dedicated syntax highlighting to make Markdown documents even easier to read and write.
- Unique features for creating Markdown documents directly in *DITA maps* and converting Markdown documents to DITA topics.
- Specialized syntax rules to combine popular syntax features from several specifications.

Markdown Editor

Oxygen XML Editor provides an intuitive, dynamic, and easy-to-use Markdown editor for writing and converting Markdown documents. It is a split-screen editor with two panels that are synchronized in real-time. The left side is a simple text editor that is specially designed for writing Markdown syntax. The right side is a WYSIWYG style preview of how changes will look in the output.

Markdown Text Editor Pane (Left Side)

The left pane is a simple text editor that is refined to accept Markdown syntax. At the same time, you still have many of the actions, options, and features that you are used to when editing any other type of document in Oxygen XML Editor.

The features of this special editor that are unique for Markdown documents include:

- **Unique Markdown Syntax Rules** - The Markdown editor in Oxygen XML Editor uses *an integration of rules* that combine rules from common default Markdown syntax along with many of the rules used in the GitHub Flavored Markdown syntax.
- **Syntax Highlighting** - The Oxygen XML Editor syntax highlighting feature is integrated into the Markdown text editor to make it easier to read and write Markdown syntax. You can even *customize the colors and styles for the syntax highlighting*.
- **Automatic Spell Checking** - The Markdown editor supports the Oxygen XML Editor *automatic spell checking feature* that reports possible misspelled words as you type. You simply need to select the ***Automatic spell check** option in the **Spell Check** preferences page*, then click the **Select editors** button and select **Markdown Editor**.

- **Helpful Toolbar and Contextual Menu Actions** - A *variety of unique actions* are available from the toolbar to help you insert proper Markdown syntax. The contextual menu also includes some common editing actions, as well as unique actions to export (convert) Markdown documents to HTML or DITA.
- **Shortcut Keys** - Many of the *shortcut keys that are most commonly used* in Oxygen XML Editor also work in the Markdown editor.

WYSIWYG Preview Pane (Right Side)

The right pane is a WYSIWYG *Preview* pane that shows a visual representation of how changes made in the left-side text editor will be converted to HTML or DITA output. The changes you make in the text editor are parsed continually and they are immediately visible in the *Preview* pane. There are two tabs available in the *Preview* pane, one for visualizing DITA output and one for visualizing HTML output. You can switch between the two tabs at the bottom of the pane.

The *Preview* pane includes the following unique features:

- **WYSIWYG Visualization** - This pane presents the Markdown syntax from the left-side text editor in a visual WYSIWYG style interface that is automatically synchronized as you type.
- **Export Options** - The **DITA** tab includes a contextual menu action to *export (convert) the current Markdown document to a DITA topic*. Similarly, the **HTML** tab includes a contextual menu action to *export (convert) it to an XHTML document*.
- **Automatic Validation** - As you edit Markdown documents, they are *validated automatically*. The conversion engine constantly tries to parse your changes and if a change results in an error that prevents the parser from converting the syntax, an error message will be displayed in the *Preview* pane or ***Results** view* at the bottom of the editor.
- **Print Feature** - The Markdown editor includes a **Print** action that is available in the contextual menu and it allows you to configure options for printing the current document as you see it in the *Preview* pane.
- **Preview Markup** - The Markdown editor includes a ***Tags Display Mode** drop-down menu* that is available on the toolbar and it allows you to control the amount of markup that is displayed in the *Preview* pane.
- **Specialized DITA Features** - The Markdown editor includes some unique, *specialized features to integrate it with the powerful DITA support* in Oxygen XML Editor.

Working with Markdown Documents in DITA on page 928
Creating New Markdown Documents on page 923

Creating New Markdown Documents

To create a new Markdown document in Oxygen XML Editor, follow these steps:

1. Click the **New** button on the toolbar or select **File** > **New**.
2. Select the **Markdown** file template (in the **New Document** folder).
3. Click the **Create** button.

   Result: A new Markdown document is created and it is opened in the specialized *Markdown Editor*.

Markdown Editor on page 921

Actions Available in the Markdown Editor

Aside from the actions that are available in Oxygen XML Editor for any type of document (such as the actions in the various menus and the common sections of the toolbar), a variety of unique actions are also available in the Markdown editor, from the toolbar and contextual menu.

Toolbar Actions

The following default actions are readily available on the toolbar when editing Markdown documents:

Header (1st Level)
Inserts an *atx-style first level header* at the cursor position.

Header (2st Level)
Inserts an *atx-style second level header* at the cursor position.

Header (3rd Level)
Inserts an *atx-style third level header* at the cursor position.

Horizontal Rule
Inserts a *horizontal rule* at the cursor position.

Bold (Strong)
Marks the selected text with *bold*.

Italic (Emphasis)
Marks the selected text with *italics*.

Strikethrough
Marks the selected text with a *strikethrough*.

Code Block
Inserts (or surrounds selected text in) a *codeblock*.

Blockquote
Inserts a *blockquote* at the cursor position.

Insert Link
Opens the **Insert Link** dialog box that allows you to define a *link* to insert at the cursor position.

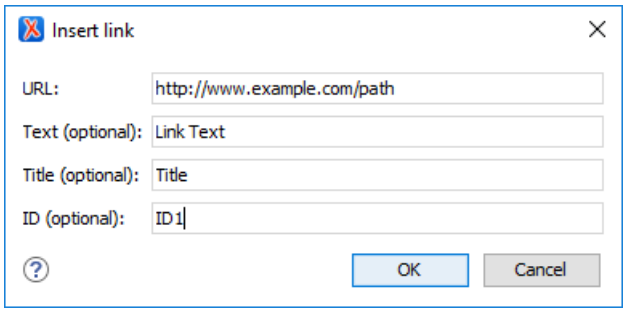

Figure 582: Insert Link Dialog Box

Insert Image

Opens the **Insert Image** dialog box that allows you to define an *image* to insert at the cursor position. You can type the URL of the image you want to insert or use browsing tools in the **Browse** drop-down menu.

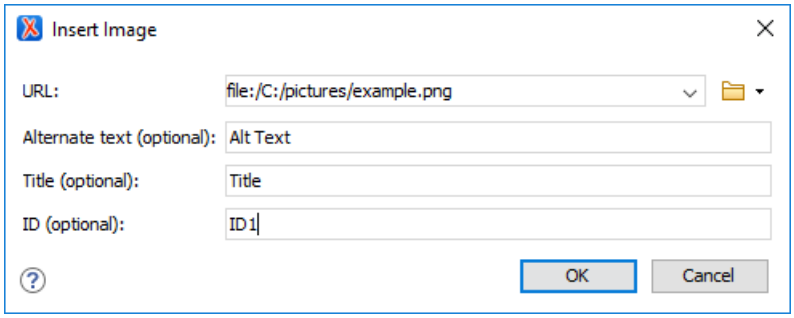

Figure 583: Insert Link Dialog Box

Insert Ordered List

Inserts an *ordered list* at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to an ordered list.

Insert Unordered List

Inserts an *unordered list* at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to an unordered list.

Insert Task List

Inserts a *task list* at the cursor position. Three child list items are also automatically inserted by default. You can also use this action to convert selected content to a task list.

Insert Table

Inserts a *table* at the cursor position.

Tags Display Mode drop-down menu

Allows you to control the amount of markup that is displayed in the *Preview* pane and offers the following choices:

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline* elements.

Full Tags

Displays full tag names without attributes for both *block* and *inline* elements.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Opens the ***Author*** *preferences page* where you can configure options in regards to *tags*, such as the default **Tags Display Mode**, **Tags Background Color**, **Tags Foreground Color**, and **Tags Font**.

Contextual Menu Actions

The following default actions are available in the contextual menu when editing Markdown documents:

Cut, Copy, Paste

Use these actions to execute the typical editing actions on the currently selected content.

Source submenu

This submenu includes the following actions:

To Upper Case

Converts the content selection to upper case characters.

To Lower Case

Converts the content selection to lower case characters.

Capitalize Lines

It capitalizes the first letter found on every new line that is selected. Only the first letter is affected, the rest of the line remains the same. If the first character on the new line is not a letter then no changes are made.

Convert Hexadecimal Sequence to Character (Ctrl + Shift + X (Command + Shift + X on OS X))

Converts a sequence of hexadecimal characters to the corresponding Unicode character. The action can be invoked if there is a selection containing a valid hexadecimal sequence or if the cursor is placed at the right side of a valid hexadecimal sequence. A valid hexadecimal sequence can be composed of 2 to 4 hexadecimal characters and may or may not be preceded by the `0x` or `0X` prefix. Examples of valid sequences: `0x0045`, `0X0125`, `1253`, `265`, `43`.

Base64 Encode/Decode submenu

This submenu includes the following actions for encoding or decoding **base64** schemes:

Import File to Encode and Insert

Encodes a file and then inserts the encoded content into the current document at the cursor position.

Decode Selection and Export to File

Decodes a selection of text from the current document and then exports (saves) the result to another file.

Encode Selection

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the ***Encoding for Base64, Base32, Hex conversions*** *option in the* ***Encoding*** *preferences page* will be used. Likewise, the same is true if the ***Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions*** *option is not selected in the* ***Messages*** *preference page*.

Decode Selection

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the ***Encoding for Base64, Base32, Hex conversions*** *option in the* ***Encoding*** *preferences page* will be used. Likewise, the same is true if

the ***Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions*** *option is not selected in the* ***Messages*** *preference page*.

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Base32 Encode/Decode submenu

This submenu includes the following actions for encoding or decoding **base32** schemes:

Import File to Encode and Insert

Encodes a file and then inserts the encoded content into the current document at the cursor position.

Decode Selection and Export to File

Decodes a selection of text from the current document and then exports (saves) the result to another file.

Encode Selection

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the ***Encoding for Base64, Base32, Hex conversions*** *option in the* ***Encoding*** *preferences page* will be used. Likewise, the same is true if the ***Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions*** *option is not selected in the* ***Messages*** *preference page*.

Decode Selection

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the ***Encoding for Base64, Base32, Hex conversions*** *option in the* ***Encoding*** *preferences page* will be used. Likewise, the same is true if the ***Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions*** *option is not selected in the* ***Messages*** *preference page*.

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Hex Encode/Decode submenu

This submenu includes the following actions for encoding or decoding **hex** schemes:

Import File to Encode and Insert

Encodes a file and then inserts the encoded content into the current document at the cursor position.

Decode Selection and Export to File

Decodes a selection of text from the current document and then exports (saves) the result to another file.

Encode Selection

Replaces a selection of text with the result of encoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the ***Encoding for Base64, Base32, Hex conversions*** *option in the* ***Encoding*** *preferences page* will be used. Likewise, the same is true if

the ***Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions*** *option is not selected in the* ***Messages*** *preference page*.

Decode Selection

Replaces a selection of text with the result of decoding that selection. By default, a dialog box is displayed that allows you to select the encoding to use. There is an option to choose to not show this dialog box in the future. In this case, the encoding that is specified in the ***Encoding for Base64, Base32, Hex conversions*** *option in the* ***Encoding*** *preferences page* will be used. Likewise, the same is true if the ***Show the dialog box for choosing the encoding for Base64, Base 32, Hex conversions*** *option is not selected in the* ***Messages*** *preference page*.

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Join and Normalize Lines (Ctrl + J (Command + J on OS X))

For the current selection, this action joins the lines by replacing the *line separator* with a single space character. It also normalizes the whitespaces by replacing a sequence of such characters with a single space.

Insert new line after (Ctrl + Alt + Enter (Command + Alt + Enter on OS X))

This action has the same result as moving the cursor to the end of the current line and pressing the *ENTER* key.

Modify All Matches

Use this option to modify (in-place) all the occurrences of the selected content (or the contiguous fragment where the cursor is located). When you use this option, a thin rectangle replaces the highlights and allows you to start editing. If matches with different letter cases are found, a dialog box is displayed that allows you select whether you want to modify only matches with the same letter case or all matches.

Open submenu

The following actions are available in this submenu:

Open File at Cursor

Opens the file at the cursor position in a new panel. If the file path represents a directory path, it will be opened in system file browser. If the file at the specified location does not exist, an error dialog box is displayed and it includes a **Create new file** button that starts the **New document** wizard. This allows you to choose the type or the template for the file. If the action succeeds, the file is created with the referenced location and name and is opened in a new editor panel.

Open File at Cursor in System Application

Opens the file (identified by its link) or web page (identified by a web link) found at cursor position. The target is opened in the default system application associated with that file type.

Compare

Opens the current file in *the* ***Compare Files*** *tool*.

Show/Hide Preview

A toggle action that shows or hides the *Preview* pane.

Export as DITA Topic

Converts the current Markdown document into a DITA topic.

Export as HTML

Converts the current Markdown document into an XHTML document.

Print (Available in the *Preview* pane)

Opens a page setup dialog box that allows you to configure printing options for the current document.

Syntax Highlighting in the Markdown Editor

Oxygen XML Editor supports syntax highlighting in the Markdown editor to improve the readability of the content and make it easier to internalize the semantics of the content.

To customize the colors or styles used for the syntax highlighting colors for Markdown documents, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)***.
2. Go to ***Editor** > **Syntax Highlight***.
3. Select and expand the **Markdown** section in the top pane.
4. Select the component you want to change and customize the colors or styles using the selectors to the right of the pane.

You can see the effects of your changes in the **Preview** pane.

Related Information:

Syntax Highlight Preferences on page 105

Markdown Editor on page 921

Automatic Validation in Markdown Documents

Markdown documents are validated automatically as you type. The conversion engine constantly tries to parse your changes to display the results in the *Preview* pane. If a change results in an error that prevents the parser from converting the syntax, an error message will be displayed in the **DITA** tab or in the ***Results** view* at the bottom of the editor.

The types of errors that will be reported include the following:

- Improper order of headers.
- The syntax in a documents begins with something other than a 1st level header.
- Tags are not closed properly if XHTML markup is used in the document.
- Invalid tag names if XHTML markup is used in the document.
- Markup is not well formed if XHTML markup is used in the document.

Markdown Editor on page 921

Working with Markdown Documents in DITA

Oxygen XML Editor includes some unique features that allow you to easily integrate Markdown documents in a DITA project. This is especially helpful for teams that have contributors who are familiar with the Markdown syntax, but they want their output to be generated from DITA projects. The integration between the Markdown editor and DITA includes actions to export or convert Markdown documents to DITA topics and the **DITA** tab in the *Preview* pane provides a visualization of how the topic will look after conversion.

Export Markdown as a DITA Topic

The Markdown editor includes an option to quickly convert the current Markdown document into a DITA topic. The **Export as DITA Topic** action is available in the contextual menu of the left-side text editor and the right-side *Preview* pane when the **DITA** tab selected.

The conversion creates a new XML file that is defined as a DITA topic and opens it in the **Text** editing mode. You can then work with the document as you would with any other DITA topic, although you may need to manually correct some issues where the parser could not properly map Markdown syntax to DITA markup.

Working with Markdown Documents in the DITA Maps Manager

Oxygen XML Editor has some specialized features that allow you to integrate Markdown documents directly into your DITA project using the ***DITA Maps Manager***. The following features are available for Markdown documents in the **DITA Maps Manager** view:

- **Insert Reference to Markdown Document** - You can use the **New**, **Reference**, and **Reference to the currently edited file** actions from the **Append Child**, **Insert Before**, or **Insert After** submenu when invoking the contextual menu in the **DITA Maps Manager** to insert a reference to a Markdown document at the selected location in the map. Markdown documents will be inserted as a topic reference (`topicref` element) with the `format` attribute set to `markdown`.
- **Validate Markdown Documents in DITA Maps** - When you use the **Validate and Check for Completeness** action from the **DITA Maps Manager** toolbar to check the integrity of the structure of a *DITA map*, Markdown documents that are referenced in the *DITA map* will be converted to DITA topics in the background and validated the same as any other DITA topic.
- **Transforming DITA Maps with Markdown Documents** - When transforming *DITA maps* that have Markdown documents referenced, the transformation will convert the Markdown documents to normal DITA output without you needing to manually convert the Markdown documents to DITA topics.
- **Manually Convert Markdown Documents to DITA Topics** - If you need to use DITA semantics that are not possible in Markdown syntax (such as content references, related links, and other DITA-specific syntax), you can manually convert the Markdown document into a DITA topic. To do so, right-click the Markdown document in the **DITA Maps Manager** and select **Refactoring** > **Convert Markdown to DITA Topic**. This will open a dialog box that allows you to configure options for converting the document to an XML file that is defined as a DITA topic.

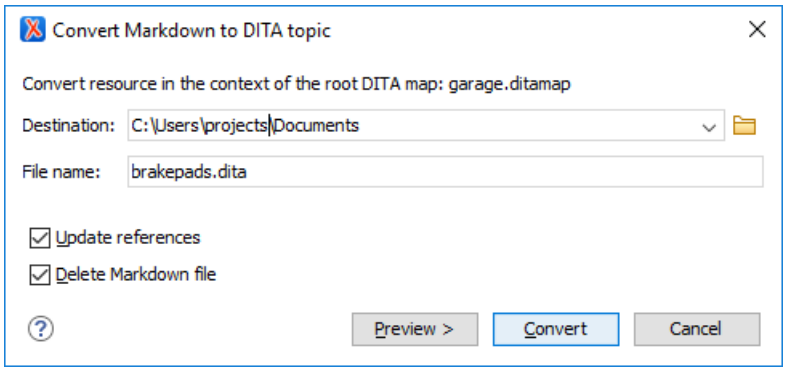

Figure 584: Convert Markdown to DITA Topic Dialog Box

This dialog box includes the following options:

Destination

The destination path for the new DITA topic.

File Name

Presents the current name and allows you to change it.

Update references

Select this option to update all references of the file in the *DITA map* and in the files referenced from the *DITA map*.

Delete Markdown file

If selected, the Markdown version of the file is deleted when the document is converted into a DITA file. If deselected (default value), when the document is converted into a DITA file, the original Markdown file is also preserved in its current location.

Preview

Select this button to display a preview of the changes Oxygen XML Editor is about to make.

Convert

Select this button to perform the conversion.

Tip: Oxygen XML Editor comes with a sample ditamap project for converting Markdown to DITA. Go to the ***Project*** *view*, open the `sample.xpr` project, and navigate to the `dita/markdown-dita` folder.

Automatic Validation in Markdown Documents on page 928

Markdown Editor Syntax Rules and Specifications

The Markdown editor in Oxygen XML Editor uses rules that were integrated from the most common set of *default Markdown syntax rules* along with many of the *GitHub Flavored Markdown rules*.

The Oxygen XML Editor implementation of the most commonly used syntax rules are as follows:

Headers

The Markdown editor supports two styles of headers, *Setext* and *Atx*.

- **Setext Style**

  Setext-style headers are underlined using equal signs (for first-level headers) and dashes (for second-level headers). Any number of equal signs or dashes will result in the same output.

  Example: Setext Style Headers

```
First-Level Header (H1)
========

Second-Level Header (H2)
------------
```

- **Atx Style**

  Atx-style headers use 1-6 hash characters at the start of the line, corresponding to header levels 1-6. Optionally, you may close atx-style headers. This is purely cosmetic and the closing hashes do not need to match the number of hashes used to open the header. It is the number of opening hashes that determines the header level.

  Example: Atx Style Headers

```
# H1 text #
## H2 text
### H3 text ######
#### H4 text
##### H5 text ###
###### H6 text
```

Horizontal Rules (for HMTL output only)

You can produce a horizontal rule tag (`<hr />`) by placing three or more hyphens, asterisks, or underscores on a line by themselves (they also need to be preceded and followed by a blank line). Optionally, they can be separated by spaces.

- **Example: Horizontal Rules**

```
* * *

*****

---------------------------------------

_ _ _ _
```

Paragraphs and Line Breaks

A paragraph is simply one or more consecutive lines of text, separated by one or more blank lines. The text at the beginning of a paragraph should not be indented with spaces or tabs. To create a new paragraph, simply insert a blank line in between them.

Important: When converting to HTML, if you break a paragraph on multiple lines (without a blank line in between them), it will create a break tag (`<br />`). When converting to DITA, the text is kept in a single paragraph in this case and a blank line is required to break a paragraph. This behavior differs slightly from the default Markdown rules.

- **Example: Paragraphs**

```
This is a paragraph that contains
two lines of text. (In HTML, a break tag is created in between the two lines)

This is a new paragraph.
```

Styling Text

The Markdown editor supports some syntax rules for styling text (such as bold, italic, or strikethrough).

- **Italic (Emphasis)** - Text wrapped with one asterisk or underscore produces an italic (emphasis) tag.

```
*italic*
_italic_
```

- **Bold (Strong)** - Text wrapped with two asterisks or underscores produces a bold (strong) tag.

```
**bold**
__bold__
```

- **Strikethrough** - In HTML only, text wrapped with two tildes (~~) produces a strikethrough tag.

```
~~strikethrough~~
```

Tip: You can also combine these styling rules. For example, `**BoldText _ItalicText_ BoldText**` would produce italicized text within bold text. Also, if you surround an asterisk or underscore with spaces, it will be treated as a literal asterisk or underscore. To produce a literal asterisk or underscore at a position where it would otherwise be used as an styling delimiter, you can escape it with a backslash (for example, `\*literal asterisks\*`.

Links

The Markdown editor supports two types of links, *inline* and *reference*. In both cases, it begins with link text that is delimited by [square brackets].

- **Inline Links**

  To create an inline link, use a set of regular parentheses immediately after the closing square bracket for the link text. Inside the parentheses, put the URL where you want the link to point, and optionally a title surrounded in quotes. Also, if you referencing a local resource on the same server, you can use relative paths.

  Examples: Inline Link

  With a title:

```
Text with [example link text](http://www.example.com/path "Title") an inline link
 with a title.
```

  Without a title:

```
Text with [example link text](http://www.example.com/path) an inline link without
 a title.
```

  Relative path:

```
Text with [example link text](/relative_path/) an inline link with relative path.
```

- **Reference Links**

  Reference-type links use a second set of square brackets that include a label (link identifier) to identify the link (it may consist of letters, numbers, spaces, and punctuation and it is not case sensitive). You can optionally use a space to separate the sets of brackets. The labels (link identifiers) are only used for creating the links and do not appear in the output.

  ```
  Text with [link text1][id 1] a reference-type link and [link text2][id_2] another
   one.
  ```

  Then, somewhere in the document, you need to define your link label on a line by itself. The link identifier must be within square brackets followed by a colon, then after one or more spaces the URL for the link. Optionally this can be followed by a title enclosed in single quotes, double quotes, or parentheses. Also, the link may optionally be enclosed in angle brackets (< >).

  ```
  [id 1]: http://example1.com/ "Optional Title"
  [id_2]: <http://example2.com/> "Optional Title2"
  ```

  Other notes about Reference Links:

  - You can put the title on a second line and use extra spaces or tabs for padding. This is useful for aesthetics when the URL is long.

    ```
    [id]: http://example.com/long/path/to/resource/here
        "Optional Title Here"
    ```
  - The label (link identifier) can be missing, in which case the link text (in square brackets) is used as the name.

    ```
    [My Link][]
    ```

    and then defined as:

    ```
    [My Link]: http://example.com/
    ```

Automatic Links

The Markdown editor supports a shortcut style for creating automatic links for URLs and email addresses. You simply surround the URL or email address with angle brackets.

Note: These automatic links only work properly in HTML conversions. The *Preview* pane may display them properly in the DITA tab, but the DITA output will not properly recognize the format.

- **URLs**

  By surrounding a URL with angle brackets, you can show the actual text of the URL while also making it clickable in the output.

  ```
  <http://example.com/>
  ```

  For example, in HTML it is converted to:

  ```
  <a href="http://example.com/">http://example.com/</a>
  ```
- **Email Addresses**

  Automatic links for email addresses work similarly, except that Markdown will also perform a bit of randomized decimal and hex entity-encoding to help obscure your address from address-harvesting *spambots*.

  ```
  <address@example.com>
  ```

  In HTML, it is converted to something like:

```
<a href="&#x6D;&#x61;i&#x6C;&#x74;&#x6F;:&#x61;&#x64;&#x64;&#x72;&#x65;
&#115;&#115;&#64;&#101;&#120;&#x61;&#109;&#x70;&#x6C;e&#x2E;&#99;&#111;
&#109;">&#x61;&#x64;&#x64;&#x72;&#x65;&#115;&#115;&#64;&#101;&#120;&#x61;
&#109;&#x70;&#x6C;e&#x2E;&#99;&#111;&#109;</a>
```

Images

The Markdown editor uses an image syntax that is intended to resemble the syntax for links, allowing for the same two types: *inline* and *reference*. In both cases, the syntax for images begin with an exclamation mark, followed by `alt` attribute text surrounded by square brackets., and then followed by a set of parentheses that contain the URL or path to the image.

- **Inline Images**

  For inline images, use a set of regular parentheses immediately after the closing square bracket for the `alt` attribute text. Inside the parentheses, put the URL or path of the image, and optionally a title surrounded in quotes.

  Examples: Inline Images

  With a title:

  ```
  Text with ![Alt text](/path/to/img.jpg "Optional title") an inline image with a
   title.
  ```

  Without a title:

  ```
  Text with ![Alt text](/path/to/img.jpg) an inline link without a title.
  ```
- **Reference Images**

  For reference-type images, use a second set of square brackets that include a label (image identifier) to identify the image (it may consist of letters, numbers, spaces, and punctuation and it is not case sensitive). You can optionally use a space to separate the sets of brackets. The labels (image identifiers) do not appear in the output.

  ```
  Text with ![Alt text1][id] a reference-type image.
  ```

  Then, somewhere in the document, you need to define your image label on a line by itself. The image identifier must be within square brackets followed by a colon, then after one or more spaces the URL or path of the image. Optionally this can be followed by a title enclosed in single quotes, double quotes, or parentheses.

  ```
  [id]: url/to/image "Optional Title"
  ```

Blockquotes

The Markdown editor uses email-style greater than characters (>) for *blockquotes*. You only need to put the > before the first line of a hard-wrapped paragraph, but it looks better (and is more clear) if you put a > before every line.

- **Example: Blockquotes**

  ```
  > This is a blockquote with two paragraphs. Lorem ipsum dolor sit amet,
  > consectetuer adipiscing elit. Aliquam hendrerit mi posuere lectus.
  > Vestibulum enim wisi, viverra nec, fringilla in, laoreet vitae, risus.
  >
  > Donec sit amet nisl. Aliquam semper ipsum sit amet velit. Suspendisse
  > id sem consectetuer libero luctus adipiscing.
  ```
- *Blockquotes* can be nested by adding additional levels of > characters.

  Example: Nested Blockquotes

  ```
  > This is the first level of quoting.
  >
  > > This is nested blockquote.
  ```

```
>
> Back to the first level.
```

- *Blockquotes* can also contain other Markdown elements (such as headers, lists, and code blocks).

  Example: Blockquotes with Other Markdown Elements

```
> ## This is a header.
>
> 1.   This is the first list item.
> 2.   This is the second list item.
>
> Here's some example code:
>
>     return shell_exec("echo $input | $markdown_script")
```

Quoting Code (Inline and Code Blocks)

The Markdown editor supports quoting code or commands inline within a sentence or in distinct blocks.

- **Inline**

  You can quote or emphasize code within a sentence (inline) with single backticks (`). The text within the backticks will not be formatted.

  Example: Inline Code Emphasis

```
This is a normal sentence with a `code` in the middle.
```

- **Code Blocks**

  You can format code or text into its own distinct block by inserting a blank line before and after the content and using at least 4 spaces (or 1 tab), or by using opening and closing triple backticks (```) on separate lines.

  Example: Code Block

```
This is a normal paragraph:

    This is a code block

This is a normal paragraph:

```
This is a code block
```
```

  One level of indentation is removed from each line of a codeblock and it continues until it reaches a line that is not indented (or until the closing backticks).

  Example: Code Block with Indentation

```
    tell application "something"
        beep
    end tell
```

  For example, in HTML the result would look like this:

```
<pre><code>tell application "Foo"
    beep
end tell
</code></pre>
```

  You can also add an optional language identifier to enable syntax highlighting in your code blocks. The Oxygen XML Editor Markdown editor supports the following languages: *Java*, *JavaScript*, *CSS*, and *Python*.

  Example: Syntax Highlighting in Code Block

```
```css
input[type="submit"] {
```
```

```
    color: white;
    font-weight: bold;
```

Inline XHTML (for HMTL output only)

The Markdown editor supports writing inline XHTML. Since Markdown is just a writing format, it requires a conversion for publishing purposes. If you are using the HTML conversion, for any markup that is not covered by Markdown syntax, you can simply use XHTML syntax.

- **Example: Inline XHTML**

```
This is a regular paragraph.

<table>
    <tr>
        <td>Col 1</td>
        <td>Col 2</td>
    </tr>
</table>

This is another regular paragraph.
```

Lists

The Markdown editor supports ordered and unordered lists. You can also insert *blockquotes* and *code blocks* inside list items. List markers typically start at the left margin, but may be indented by up to three spaces.

- **Unordered Lists**

  For unordered lists, you can use asterisks (*), plus signs (+), and hyphens (-) interchangeably.

```
* List item 1
+ List item 2
- List item 3
```

- **Ordered Lists**

  For ordered lists, use numbers followed by periods. The actual numbers you use have no effect on the output. It simply converts them to list items within an ordered list an the actual number of list items will determine the numbers in the output.

```
1. List item 1
8. List item 2
5. List item 3
```

- **Nested Lists**

  You can create nested lists by indenting lines by two spaces.

```
1. Ordered list item 1
  1. Nested ordered list item 1
  2. Nested ordered list item 2
    * 2nd level nested unordered list item 1
    * 2nd level nested unordered list item 2
      * 3rd level nested unordered list item 1
2. Ordered list item 2
```

- **Paragraphs Inside Lists**

  If list items are separated by blank lines, Markdown will wrap the items in a paragraph in the output.

```
* List item 1

* List item 2
```

  For both DITA and HTML output, this would result in:

```
<ul>
<li><p>List item 1</p></li>
<li><p>List item 2</p></li>
</ul>
```

- **Multiple Paragraphs Inside Lists**

  List items may consist of multiple paragraphs. Each subsequent paragraph in a list item must be indented by either 4 spaces or one tab. Optionally, you can also indent each line of a paragraph to make it look nicer.

```
1.  This is a list item with two paragraphs. Lorem ipsum dolor
    sit amet, consectetuer adipiscing elit. Aliquam hendrerit
    mi posuere lectus.

    Vestibulum enim wisi, viverra nec, fringilla in, laoreet
    vitae, risus. Donec sit amet nisl. Aliquam semper ipsum
    sit amet velit.

2.  Suspendisse id sem consectetuer libero luctus adipiscing.
```

- **Blockquotes Inside Lists**

  To put a *blockquote* within a list item, the blockquote delimiters (>) need to be indented so that it is under the first letter of the text after the list item marker.

```
*   A list item with a blockquote:
    > This is a blockquote
    > inside a list item.
```

- **Code Blocks Inside Lists**

  To put a code block within a list item, insert an empty line in between the list item and the code block, and the code block needs to be indented twice (with 8 spaces or 2 tabs), or if you are using the triple backticks method, the opening triple backtick needs to be indented with 4 spaces or 1 tab.

```
*   A list item with a code block:

        This is a code block inside a list item

    ```
    This is a code block inside a list item using the backticks method
    ```
```

Task Lists

You can create task lists by prefacing list items with a hyphen followed by a space followed by square brackets (`- [ ]`). To mark a task as complete, use `- [x]`.

- **Example: Task Lists**

```
- [ ] Unfinished task 1
- [x] Finished task 2
```

Definition Lists

You can create definition lists by using a colon plus a space for each list item.

- **Example: Definition Lists**

```
Term 1
: Definition A
: Definition B
```

Tables

You can create tables in the Markdown editor by using pipes (`|`) and hyphens (`-`).

- **Creating a Table**

  Pipes are used to separate each column, while hyphens are used to create column headers. The pipes on either end of the table are optional. Cells can vary in width and do not need to be perfectly aligned within columns, but there must be at least three hyphens in each column of the header row.

```
| First Header  | Second Header |
| ------------- | ------------- |
| Column 1 Row 1 Cell  | Column 2 Row 1 Cell  |
| Column 1 Row 2 Cell  | Column 2 Row 2 Cell  |
```

- **Formatting Rules in Table Cells**

  You can use formatting rules inside the cells of the table (such as links, inline code blocks, and text styling).

```
| First Header  | Second Header |
| --- | --- |
| `inline code`  | Content with **bold text** inside cell  |
```

- **Aligning Text in Tables**

  You can align text to the left, right, or center of a column by including colons (`:`) to the left, right, or on both sides of the hyphens within the header row.

```
| Left-aligned | Center-aligned | Right-aligned |
| :---         |     :---:      |          ---: |
| Content Cell | Content Cell   | Content Cell  |
```

- **Joining Cells (Span a Cell Over Multiple Columns)**

  You can join cells horizontally (span a cell over multiple columns) by using multiple consecutive pipe characters (`|`) to the right of the particular cell. The number of consecutive pipes indicate the number of columns the cell will span (`||` for two, `|||` for three, and so on).

```
| First Header | Second Header | Third Header | Fourth Header |
| ------------ | ------------- | ------------ | ------------- |
| Content Cell | *Cell Span Over 3 Columns* |||
```

Emoji

You can add *emoji* in the Markdown editor by surrounding the EMOJICODE with colons (`:EMOJICODE:`).

- **Example: Emoji**

```
:smile:
:laughing:
```

  The resulting emoticons will appear in the output, but they are not displayed in the *Preview* pane.

  For a full list of available emoji codes, see *Emoji Cheat Sheet*.

Backslash Escapes

You can ignore Markdown formatting by using backslash escapes (`\`) to generate literal characters that would otherwise have special meaning in the Markdown syntax. For example, if you want to surround a word with literal asterisks (instead of an italic or emphasis tag), you can use backslashes to escape the asterisks.

```
\*literal asterisks\*
```

The Markdown editor provides backslash escapes for the following characters:

```
\   backslash
`   backtick
*   asterisk
_   underscore
{}  curly braces
[]  square brackets
()  parentheses
```

```
#   hash mark
+   plus sign
-   minus sign (hyphen)
.   dot
!   exclamation mark
```

Automatic Escaping for Special Characters

The Markdown editor includes support for automatically escaping special characters such as angle brackets (< >) and ampersands (&). If you want to use them as literal characters, you must escape them as entities, as in the table below. The exception to this is in HTML output, if the special characters for a valid tag (for example, <b>), they are treated as literal characters and escaping is not necessary.

Literal Character	Escaping Code
<	<
>	>
&	&

Footnotes

The Markdown editor in Oxygen XML Editor supports normal and inline footnotes. The following examples show the required syntax.

- **Example: Normal Footnote**

```
Here is a footnote reference,[^1]

[^1]: Here is the footnote.
```

- **Example: Normal Footnote with Multiple Blocks**

```
Here is a footnote reference,[^longnote]

[^longnote]: Here is the footnote with multiple blocks.

    Subsequent paragraphs are indented with 4 spaces or 1 tab to show that they
belong to the previous footnote.
```

- **Example: Inline Footnote**

```
Here is an inline note.^[Inlines notes are easier to write, since
you don't have to pick an identifier and move down to type the
note.]
```

Editing Non-XML Files

While Oxygen XML Editor specializes in XML-related technologies, you can also use it to create and edit various types of non-XML files. Non-XML files are opened in a simple text editor and many of the helpful features that are commonly used when editing XML files in the Oxygen XML Editor **Text** editing mode are available in this simple editor.

Types of Non-XML Files That are Supported

Some of the types of non-XML files that can be created and edited in Oxygen XML Editor include:

- *Markdown*
- Java
- C++
- C
- PHP
- Perl
- Properties
- SQL
- Shell executables
- Batch
- Python
- Text

Features Available in the Simple Text Editor

When editing non-XML files in the simple text editor, the features that are available include the following:

- **Project Support** - The unique *features that are designed to help you work with projects* are available for all types of files.
- **Shortcut Actions** - Many of the *shortcut actions that are available in **Text** mode* are also available in the simple text editor.
- **Drag and Drop** - The normal drag and drop support is available in the simple text editor.
- **Content Selection Features** - The *content selection shortcuts* that are available in **Text** mode (including the *Rectangular Selection* feature) are also available in the simple text editor.
- **Bookmarks** - You can use *bookmarks to mark positions* in any type of file so that you can return to it later.
- **Convert Hexadecimal Characters** - You can *convert a sequence of hexadecimal characters to the corresponding Unicode character*.
- **Encoding/Decoding Actions** - Contextual menu actions are available to *encode or decode Base64, Base 32, and Hex schemes*.
- **Code Templates** - You can define your own *code templates* for any type of file and use the *Content Completion Assistant* to invoke them.
- **Syntax Highlighting** - Non-XML files also support syntax highlighting with dedicated coloring schemes. To customize them, *open the **Preferences** dialog box **(Options > Preferences)*** and go to ***Editor > Syntax Highlight***. Select and expand the appropriate section in the top pane for the type of file you are editing and you can see the effects of your changes in the **Preview** pane.
- **Find/Replace** - You can use the ***Find/Replace** action* to find or replace all the occurrences of a word or string of characters in any type of file that you are editing.
- **File Comparison Tool** - The ***Compare Files** tool* can also be used to compare non-XML files.

Loading Large Documents

When you open a document with a file size larger than the limit configured in ***Open/Save** preferences*, Oxygen XML Editor prompts you to choose whether you want to optimize the loading of the document for large files or for huge files.

If your file has a size smaller than 300 MB, the recommended approach is ***Optimize loading for large files***. For documents that exceed 300 MB the recommended approach is ***Optimize loading for huge files***.

File Sizes Smaller than 300 MB

For editing large documents (file size up to 300 Megabytes), a special memory optimization is implemented on loading such a file so that the total memory allocated for the application is not exceeded.

A temporary buffer file is created on disk so you have to make sure that the available free disk space is at least double the size of the large file that you want to edit. For example, Oxygen XML Editor can load a 200-Megabytes file using a minimum memory setting of 512 Megabytes and at least 400-Megabytes free disk space.

The increase of the maximum size of editable files includes the following restrictions:

- A file larger than the value of the above option is edited only in **Text** mode.
- The *automatic validation* is not available when editing a very large file.
- The XPath filter is disabled in *the Find/Replace dialog box*.
- The bidirectional Unicode support (right-to-left writing) is disabled.
- *The **Format and indent the document on open** option* is deselected for non-XML documents. For XML documents, it is done optimizing the memory usage but without respecting the options set in *the **Format** preferences page*.
- Less precise localizations for the results of an *XPath expression*.

File Sizes Greater than 300 MB

Files tend to become larger and larger mostly because they are frequently used as a format for database export or for porting between different database formats. Traditional text editors simply cannot handle opening these huge export files, some having sizes exceeding one gigabyte, because all the file content must be loaded in memory before the user can actually view it.

The file is split in multiple pages (each having about 1MB in size). Each page is individually loaded (and edited) in the **Text** mode by using the special horizontal slider located at the top of the editing area. The loading operation is very fast and has no upper limit for the size of the loaded file.

The increase of the maximum size of editable files includes the following restrictions:

- For XML files, only the UTF-8, UTF-16, and ASCII encodings are handled; for all non-XML files, the content is considered to be UTF-8.
- Files can be edited in **Text** editing mode only.
- The *automatic validation* is disabled.
- The XPath filter is disabled in the ***Find/Replace** dialog box*.
- The bidirectional Unicode support (right-to-left writing) is disabled.
- *The **Format and indent the document on open** option* is deselected for non-XML documents. For XML documents, the format and indent operation it is done optimizing the memory usage, but it ignores the options set in *the **Format** preferences page*.
- The ***Outline** view* is not supported.
- The file content is soft wrapped by default.
- The ***Find/Replace** dialog box* only supports the **Find** action.
- Saving changes is possible if **Safe save** is activated.
- The **undo** operation is not available if you go to other pages and come back to the modified page. the Undo operation loses its previous states if the back and forth between

Editing Documents with Long Lines

When working with documents that contain lines of text that exceed the boundaries of your monitor, you might want to see the text wrapped. To do so, use one of the following methods:

- Press **Ctrl + Shift + Y (Command + Shift + Y on OS X)** to toggle the line wrap feature for the current document only.
- Select the ***Line wrap*** option in the **Text** preferences page to apply the line wrap to all documents.

Features that Might be Affected by Wrapping Lines of Text

Documents that contain thousands of characters per line can affect the performance of Oxygen XML Editor **Text** mode. When a certain line length limit is reached (controlled from the *Optimize loading for documents with lines longer than (Characters)* on page option), Oxygen XML Editor prompts you to wrap the lines of text. By doing so, the following features may be affected to maintain a reasonable level of productivity:

- The editor uses the `Monospaced` font.
- You cannot set font styles.
- *Automatic validation* is disabled.

- *Automatic spell checking* is disabled.
- When editing XML documents, the **XPath** field is disabled in the ***Find/Replace*** *dialog box*.
- Less precise localization for executed XPath expressions in XML documents. The XPath executions use SAX sources for a smaller memory footprint. We recommend using XPath 2.0 instead of XPath 1.0 because it features an increased execution speed and uses a smaller memory footprint. Running an XPath expression requires additional memory of about 2 or 3 times the size of the document on disk.

Handling Read-Only Files

If a file marked as read-only is opened in Oxygen XML Editor you can by default perform modifications to it. This behavior is controlled by the ***Can edit read only files*** *option*. When attempting to save such files you will be prompted to save them to another location.

You can check out the read-only state of the file by looking in the ***Properties*** *view*. If you modify the file properties from the operating system and the file becomes writable, you can modify it on the spot without having to reopen it.

The read-only state is marked with a lock decoration that appears in the editor tab and specified in the tooltip for a certain tab.

Scratch Buffer

The **Scratch Buffer** view can be used for storing fragments of arbitrary text during the editing process. It can be used to drop bits of paragraphs (including arbitrary XML markup fragments) while rearranging and editing the document and also to drag and drop fragments of text from the Scratch Buffer to the editor panel. The **Scratch Buffer** is basically a text area offering XML syntax highlight. The view's contextual menu contains basic edit actions such as **Cut**, **Copy**, and **Paste**.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

XML Digital Signatures

This chapter explains how to apply and verify digital signatures on XML documents.

Digital Signatures Overview

Digital signatures are widely used as security tokens, not just in XML. A *digital signature* provides a mechanism for assuring integrity of data, the authentication of its signer, and the non-repudiation of the entire signature to an external party:

- A *digital signature* must provide a way to verify that the data has not been modified or replaced to ensure integrity.
- The *signature* must provide a way to establish the identity of the data's signer for authentication.
- The *signature* must provide the ability for the data's integrity and authentication to be provable to a third party for non-repudiation.

A *public key system* is used to create the digital signature and it's also used for verification. The signature binds the signer to the document because digitally signing a document requires the originator to create a hash of the message and then encrypt that hash value with their own private key. Only the originator has that private key and that person is the only one who can encrypt the hash so that it can be unencrypted using their public key. The recipient, upon receiving both the message and the encrypted hash value, can decrypt the hash value, knowing the originator's public key. The recipient must also try to generate the hash value of the message and compare the newly generated hash value with the unencrypted hash value received from the originator. If the hash values are identical, it proves that the originator created the message, because only the actual originator could encrypt the hash value correctly.

XML Signatures can be applied to any digital content (data object), including XML (see W3C Recommendation, *XML-Signature Syntax and Processing*). An XML Signature may be applied to the content of one or more resources:

- Enveloped or enveloping signatures are applied over data within the same XML document as the signature
- Detached signatures are applied over data external to the signature element; the signature is "detached" from the content it signs. This definition typically applies to separate data objects, but it also includes the instance where the signature and data object reside within the same XML document but are sibling elements.

The *XML Signature* is a method of associating a key with referenced data. It does not normatively specify how keys are associated with persons or institutions, nor the meaning of the data being referenced and signed.

The original data is not actually signed. Instead, the signature is applied to the output of a chain of *canonicalization* and transformation algorithms, which are applied to the data in a designated sequence. This system provides the flexibility to accommodate whatever "normalization" or desired preprocessing of the data that might be required or desired before subjecting it to being signed.

Since the signature is dependent on the content it is signing, a signature produced from a *non-canonicalized* document could possibly be different from one produced from a *canonicalized* document. The *canonical* form of an XML document is physical representation of the document produced by the method described in this specification. The *XML canonicalization* method is the algorithm defined by this specification that generates the canonical form of a given XML document or document subset. *XML canonicalization* is designed to be useful for applications that require the ability to test whether or not the information content of a document or document subset has been changed. This is done by comparing the *canonical* form of the original document before application processing with the *canonical* form of the document result of the application processing.

A digital signature over the *canonical* form of an XML document or document subset would allows the signature digest calculations to be oblivious to changes in the original document's physical representation. During signature generation, the digest is computed over the *canonical* form of the document. The document is then transferred to the relying party, which validates the signature by reading the document and computing a digest of the *canonical* form of the received document. The equivalence of the digests computed by the signing and relying parties (hence, the equivalence of the *canonical* forms for which they were computed) ensures that the information content of the document has not been altered since it was signed.

The following *canonicalization algorithms* are used in Oxygen XML Editor:

- **Canonical XML (or Inclusive XML Canonicalization)** (*XMLC14N*) - Used for XML where the context doesn't change.

  Inclusive Canonicalization copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. *Inclusive Canonicalization* is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the *Inclusive Canonicalization* will copy them and the signature will be invalid.
- **Exclusive XML Canonicalization** (*EXCC14N*) - Designed for *canonicalization* where the context might change.

  Exclusive Canonicalization just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.

The *canonicalization* method can specify whether or not comments should be included in the *canonical* form output by the *XML canonicalization* method. If a *canonical* form contains comments corresponding to the comment nodes in the input node-set, the result is called *canonical* XML with comments. In an uncommented *canonical* form comments are removed, including delimiter for comments outside document element.

The three operations. ***Canonicalize***, ***Sign***, and ***Verify Signature***, are available from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

Certificates

A certificate is a digitally signed statement from the issuer (an individual, an organization, a website or a firm), saying that the public key (and some other information) of some other entity has a particular value. When data is digitally signed, the signature can be verified to check the data integrity and authenticity. Integrity means that the data has not been modified. Authenticity means the data comes indeed from the entity that claims to have created and signed it. Certificates are kept in special repositories called *keystores*.

All *keystore* entries (key and trusted certificate entries) are accessed via unique aliases. An alias must be assigned for every new entry of either a key or certificate as a reference for that entity. No *keystore* can store an entity if its alias already exists in that *keystore* and cannot store trusted certificates generated with keys in its *keystore*.

Oxygen XML Editor provides two types of *keystores*: Java Key Store (JKS) and Public-Key Cryptography Standards version 12 (PKCS-12). A *keystore* file is protected by a password. In a PKCS 12 *keystore* you should not store a certificate without alias together with other certificates, with or without alias, as in such a case the certificate without alias cannot be extracted from the *keystore*.

To configure the options for a certificate or to validate it, *open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to **XML** > **XML Signing Certificates**. This opens *the certificates preferences page*.

Canonicalizing Files

You can select the *canonicalization* algorithm to be used for a document from the dialog box that is displayed by using the **Canonicalize** action that is available from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

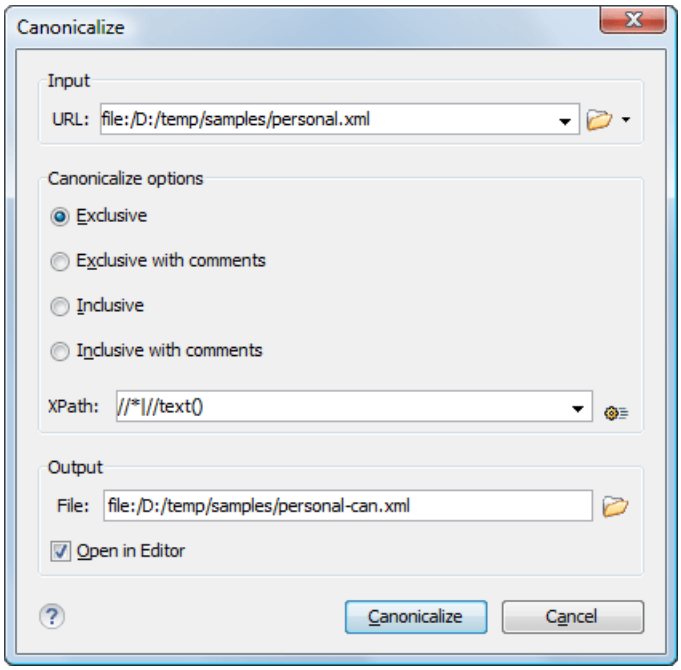

Figure 585: Canonicalization Settings Dialog Box

The **Canonicalize** dialog box allows you to set the following options:

- **Input URL** - Available if the **Canonicalize** action was selected from the **Tools** menu. It allows you to specify the location of the input file.

- **Exclusive** - If selected, the exclusive (uncommented) *canonicalization* method is used.

  Note: *Exclusive Canonicalization* just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.
- **Exclusive with comments** - If selected, the exclusive with comments *canonicalization* method is used.
- **Inclusive** - If selected, the inclusive (uncommented) *canonicalization* method is used.

  Note: *Inclusive Canonicalization* copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive *Canonicalization* is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive *Canonicalization* will copy them and the signature will be invalid.
- **Inclusive with comments** - If selected, the inclusive with comments *canonicalization* method is used.
- **XPath** - The XPath expression provides the fragments of the XML document to be signed.
- **Output** - Available if the **Canonicalize** action was selected from the **Tools** menu. It allows you to specify the output file path where the signed XML document will be saved.
- **Open in editor** - If selected, the output file will be opened in the editor.

Digital Signatures Overview on page 941

Signing Files

You can select the type of signature to be used for documents from a signature settings dialog box. To open this dialog box, select the **Sign** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu.

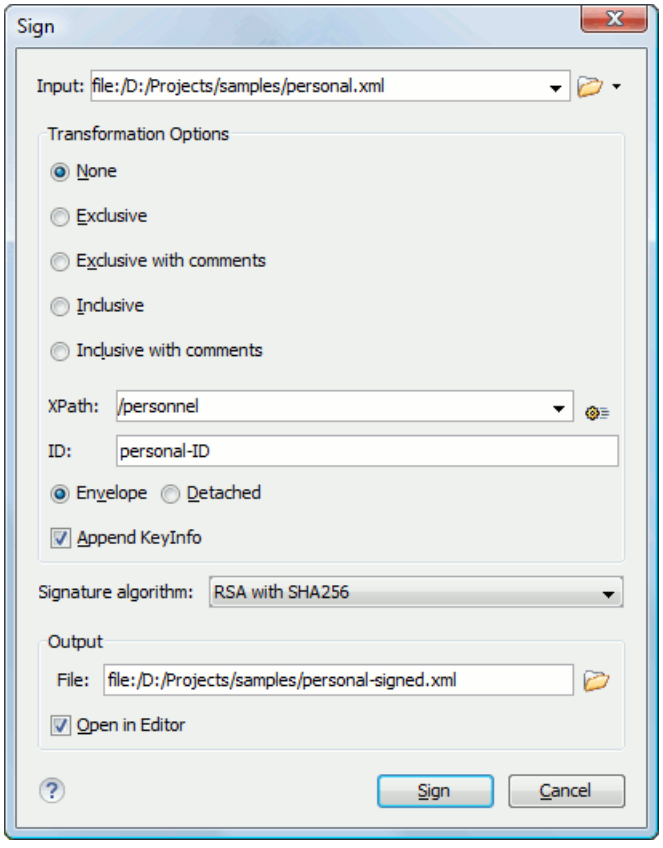

Figure 586: Signature Settings Dialog Box

The following options are available:

Note: If Oxygen XML Editor could not find a valid certificate, a link is provided at the top of the dialog box that opens the *XML Signing Certificates preferences page* where you can configure a valid certificate.

- **Input** - Available if the **Sign** action was selected from the **Tools** menu. Specifies the location of the input URL.
- **Transformation Options** - See the *Digital Signature Overview* section for more information about these options.
  - **None** - If selected, no *canonicalization* algorithm is used.
  - **Exclusive** - If selected, the exclusive (uncommented) *canonicalization* method is used.

    Note: *Exclusive Canonicalization* just copies the namespaces you are actually using (the ones that are a part of the XML syntax). It does not look into attribute values or element content, so the namespace declarations required to process these are not copied. This is useful if you have a signed XML document that you want to insert into other XML documents (or you need self-signed structures that support placement within various XML contexts), as it will ensure the signature is verified correctly each time.
  - **Exclusive with comments** - If selected, the exclusive with comments *canonicalization* method is used.
  - **Inclusive** - If selected, the inclusive (uncommented) *canonicalization* method is used.

    Note: *Inclusive Canonicalization* copies all the declarations, even if they are defined outside of the scope of the signature, and all the declarations you might use will be unambiguously specified. Inclusive *Canonicalization* is useful when it is less likely that the signed data will be inserted in other XML document and it is the safer method from the security standpoint because it requires no knowledge of the data that are to be secured to safely sign them. A problem may occur if the signed document is moved into another XML document that has other declarations because the Inclusive *Canonicalization* will copy them and the signature will be invalid.
  - **Inclusive with comments** - If selected, the inclusive with comments *canonicalization* method is used.
- **XPath** - The XPath expression provides the fragments of the XML document to be signed.
- **ID** - Provides ID of the XML element to be signed.
- **Envelope** - If selected, the *enveloped* signature is used. See the *Digital Signature Overview* for more information.
- **Detached** - If selected, the *detached* signature is used. See the *Digital Signature Overview* for more information.
- **Append KeyInfo** - If this option is selected, the `ds:KeyInfo` element will be added in the signed document.
- **Signature algorithm** - The algorithm used for signing the document. The following options are available: **RSA with SHA1**, **RSA with SHA256**, **RSA with SHA384**, and **RSA with SHA512**.
- **Output** - Available if the **Sign** action was selected from the **Tools** menu. Specifies the path of the output file where the signed XML document will be saved.
- **Open in editor** - If selected, the output file will be opened in Oxygen XML Editor.

Verifying Signature on page 945
Example of How to Digitally Sign XML Files or Content on page 946

Verifying Signature

You can verify the signature of a file by selecting the **Verify Signature** action from the **Source** submenu when invoking the contextual menu in **Text** mode or from the **Tools** menu. The **Verify Signature** dialog box then allows you to specify the location of the file whose signature is verified.

If the signature is valid, a dialog box displays the name of the signer. Otherwise, an error shows details about the problem.

Signing Files on page 944
Example of How to Digitally Sign XML Files or Content on page 946

Example of How to Digitally Sign XML Files or Content

Suppose you want to digitally sign an XML document, but more specifically, suppose you have multiple instances of the same element in the document and you just want to sign a specific ID. Oxygen XML Editor includes a signature tool that allows you to digitally sign XML documents or specific content.

The Oxygen XML Editor installation directory includes a `samples` folder that contains a file called `personal.xml`. For the purposes of this example, this file will be used to demonstrate how to digitally sign specific content. Notice that this file has multiple `person` elements inside the `personnel` element. Suppose you want to digitally sign the specific `person` element that contains the `id=robert.taylor`. To do this, follow this procedure:

1. Open the `personal.xml` file in Oxygen XML Editor in **Text** editing mode.
2. Right-click anywhere in the editor and select the **Sign** action from the **Source** submenu.
   The **Sign** dialog box is displayed.

   Tip: If you want to sign a file but create a new output file so that the original file remains unchanged, use the **Sign** action from the **Tools** menu. Selecting the action from this menu will allow you to choose an input file and output file in the **Sign** dialog box.
3. If Oxygen XML Editor cannot find a valid certificate, click the link at the top of the dialog box to **configure a valid certificate**. This opens the ***XML Signing Certificates*** *preferences page* that allows you to configure and validate a certificate.
4. Once a valid certificate is recognized, continue to configure the **Sign** dialog box.
   a) Select one of *the* ***Transformation Options***. For the purposes of this example, select the **Inclusive with comments** option.
   b) Specify the appropriate **XPath** expression for the specific element that needs to be signed. For this example, type `/personnel/person` in the **XPath** text box.
   c) Enter the specific **ID** that needs to be signed. For this example, type `robert.taylor` in the **ID** field.
   d) Select *the* ***Envelope*** *option* and leave the other options as their default values.

   The digital signature is added at the end of the XML document, just before the end tag. It is always added at the end of the document, even if you only sign specific content within the document.
5. You can verify the signature by choosing the **Verify Signature** action from the **Source** submenu of the contextual menu.

Verifying Signature on page 945

Compare Files or Directories

Oxygen XML Editor provides a simple means of performing file and folder comparisons. You can see the differences in your files and folders and merge the changes. You can also use the file comparison to compare fragments or files inside zip-based archives.

There are two types of comparison tools: **Compare Directories** or **Compare Files**. These utilities are available from the **Tools** menu or can be opened as stand-alone applications from the Oxygen XML Editor installation folder (`diffDirs.exe` and `diffFiles.exe`).

Starting the Tools from a Command Line

The comparison tools can also be started by using command-line arguments. In the installation folder there are two executable shells (`diffFiles.bat` and `diffDirs.bat` on Windows, `diffFiles.sh` and `diffDirs.sh` on OS X and Linux). To specify files or directories to compare, you can pass command-line arguments to each of these shells. The arguments can point to file or folder paths in directories or archives (supported formats: *zip*, *docx*, and *xlsx*).

Directory Comparison Example

To start a *comparison between the two directories*, use the following construct: `diffDirs.bat/diffDirs.sh [directory path 1] [directory path 2]`. If you pass only one argument, you are prompted to manually choose the second directory or archive.

For example, to start a comparison between two Windows directories, the command line would look like this:

```
diffDirs.bat "c:\documents new" "c:\documents old"
```

Tip: If there are spaces in the path names, surround the paths with quotes.

File Comparison Example

To start a *comparison between 2 or 3 files*, use the following construct: `diffFiles.bat/diffFiles.sh [path to left file] [path to right file] [path to base file]`.

If three files are specified, the tool will start in the *3-way comparison mode*. If only two files are specified, the tool will start in the *2-way comparison mode*. The first specified file will be added to the left panel in the comparison tool, the second file to the right panel, and the optional third file will be the base (ancestor) file used for a 3-way comparison. If you pass only one argument, you are prompted to manually choose another file.

For example, to do a 3-way comparison on Windows, the command line would look like this:

```
diffFiles.bat "c:\docs\file 1" "c:\docs\file 2" c:\docs\basefile
```

Tip: If there are spaces in the path names, surround the paths with quotes.

Compare Files

The **Compare Files** tool can be used to compare files or XML file fragments. The tool provides a mechanism for comparing two files or fragments, as well as the mechanism for a three-way comparison. The utility is available from the **Tools** menu or can be opened as a stand-alone application from the Oxygen XML Editor installation folder (`diffFiles.exe`).

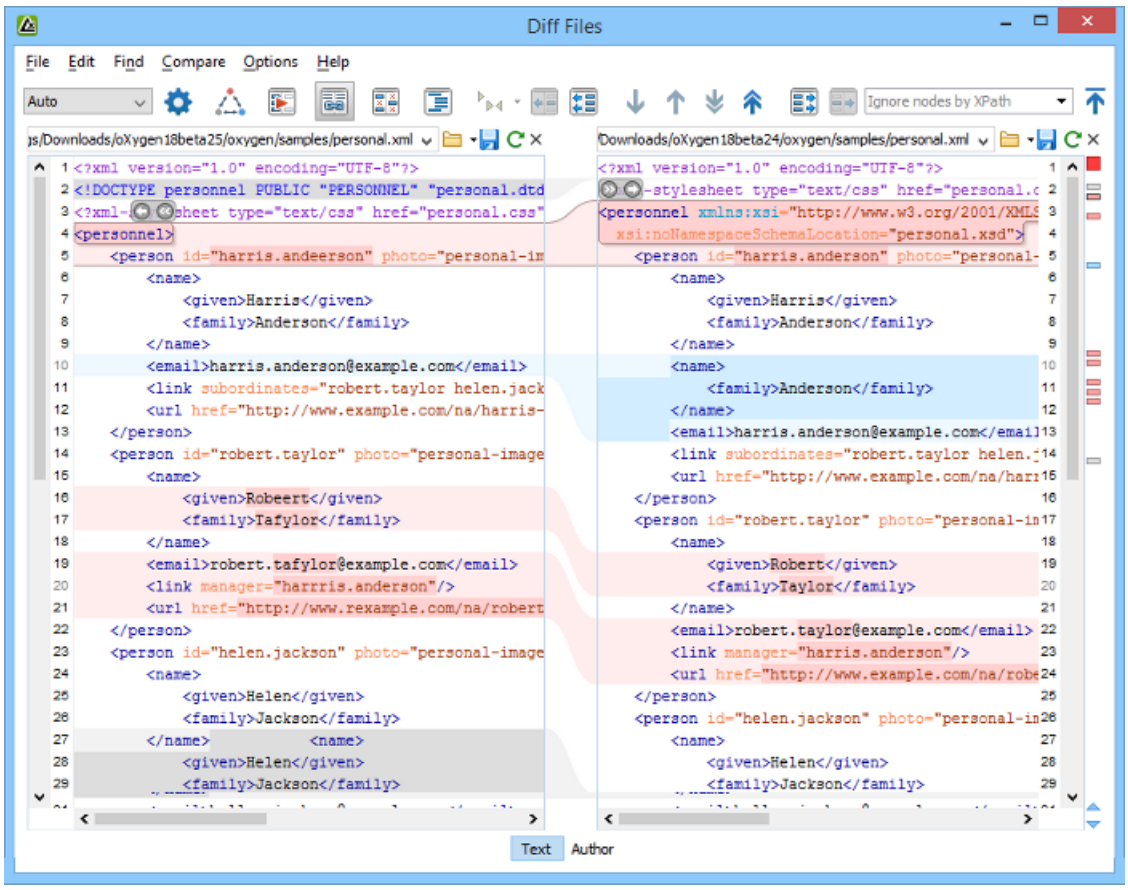

Figure 587: Compare Files Tool

Two-Way Comparisons

The **Compare Files** tool can be used to compare the differences between two files or XML fragments.

Compare Files

To perform a two-way comparison, follow these steps:

1. Open a file in the left panel and the file you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down menu.

   Step Result: The selected files are opened in the two side-by-side editors. A text editing mode is used to offer a better view of the differences.
2. To highlight the differences between the two files, click the **Perform File Differencing** button from the toolbar.
3. You can use the drop-down menu on the left side of the toolbar to change the *algorithm* for the operation.
4. You can also use the **Diff Options** button to access the **Files Comparison** preferences page where you can choose to ignore certain types of markup and configure various options.
5. If you are comparing XML documents using the **XML Fast** or **XML Accurate** algorithms, you can enter an XPath 2.0 expression in the **Ignore nodes by XPath** text field to ignore certain nodes from the comparison.

The resulting comparison will show you differences between the two files. The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes. This layout allows you to easily identify and focus on a group of related changes.

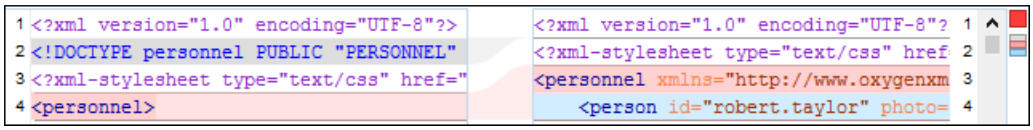

Figure 588: Two-Way Differences

Highlighting Colors

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the ***Files Comparison / Appearance*** *preferences page*, but the default colors and their shades mean the following:

- **Pink** - Identifies modifications on either side.
- **Gray** - Identifies an addition of a node in the left side (your outgoing changes).
- **Blue** - Identifies an addition of a node in the right side (incoming changes).
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Comparing Fragments (Copy/Paste)

To compare XML file fragments, you need to copy and paste the fragments you want to compare into each side, without selecting a file. If a file is already selected, you need to close it using the **Close (Ctrl + W (Command + W on OS X))** button, before pasting the fragments. Other notes for pasting fragments:

- As long as the fragment is more than 10 characters, the application will attempt to automatically detect the content type. It can detect the following types: XML, DTD, CSS, JSON, and Markdown (if it starts with #). If one of those content types is detected, the fragments will be displayed with syntax highlights.
- If you save modified fragments, a dialog box opens that allows you to save the changes as a new document.

Navigate Differences

To navigate through differences, do one of the following:

- Use the navigation buttons on the toolbar (or in the **Compare** menu).

- Select a block of differences by clicking its small colored marker in the overview ruler located in the right-most part of the window. At the top of the overview ruler there is a success indicator that turns green where there are no differences, or red if differences are found.
- Click a colored area in between the two text editors.

Editing Actions

You can edit the files directly in either editing pane. The two editors are constantly synchronized and the differences are refreshed when you save the modified document or when you click the  **Perform File Differencing** button.

A variety of actions are available on the *toolbar* and in the *various menus* (these same actions are also available in the contextual menu in both editing panes). The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

 **Append left change to right and**  **Append right change to left**

Copies the content of the selected change from one side and appends it on the other, according to the content of the corresponding change. As a result, the side where the arrow points to will contain the changes from both sides.

 **Copy change from left to right and**  **Copy change from right to left**

Replaces the content of a change from one side with the content of the corresponding change from the other side.

 **Remove change**

Rejects the change on the particular side and preserves the particular content on the other side.

Two-Way Diff Algorithms

Oxygen XML Editor offers the following two-way diff algorithms to compare files or fragments:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Characters** - Computes the differences at character level, meaning that it compares two files or fragments looking for identical characters. This algorithm is not available when the file comparison is in **Author** mode.
- **Words** - Computes the differences at word level, meaning that it compares two files or fragments looking for identical words. This algorithm is not available when the file comparison is in **Author** mode.
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **Syntax Aware** - Computes differences for known file types or fragments. This algorithm splits the files or fragments into sequences of *tokens* and computes the differences between them. The meaning of a *token* depends on the type of compared files or fragments.

  Known file types include those listed in the **New** dialog box, such as XML file types (XSLT files, XSL-FO files, XSD files, RNG files, NVDL files, etc.), XQuery file types (`.xquery`, `.xq`, `.xqy`, `.xqm` extensions), DTD file types (`.dtd`, `.ent`, `.mod` extensions), TEXT file type (`.txt` extension), or PHP file type (`.php` extension).

  For example:

  - When comparing XML files or fragments, a token can be one of the following:
    - The name of an XML tag
    - The < character
    - The /> sequence of characters
    - The name of an attribute inside an XML tag
    - The = sign
    - The " character
    - An attribute value
    - The text string between the start tag and the end tag (a text node that is a child of the XML element corresponding to the XML tag that encloses the text string)

- When comparing plain text, a token can be any continuous sequence of characters or any continuous sequence of whitespaces, including a new line character.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Three-Way Comparisons

Oxygen XML Editor also includes a three-way comparison feature to help you solve conflicts and merge changes between multiple modifications. It is especially helpful for teams who have multiple authors editing and committing the same documents. It provides a comparison between a local change, another change, and the original base revision. Some additional advantages include:

- Visualize and merge content that was modified by you and another member of your team.
- Marks differences correctly even when the document structure is rearranged.
- Allows you to merge XML-relevant modifications.

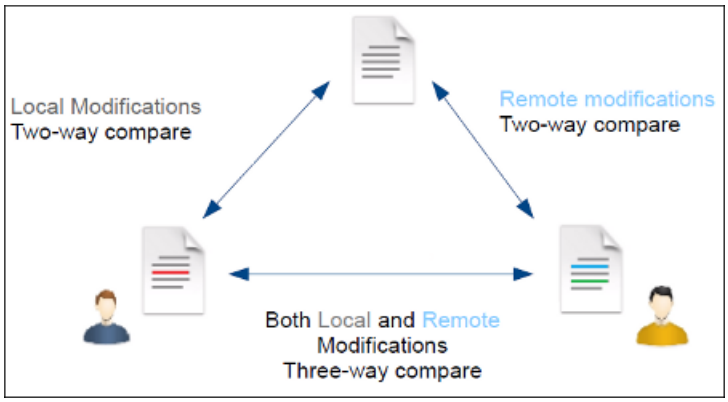

Figure 589: Three-Way Comparison

Compare Files

To perform a three-way comparison, follow these steps:

1. Open a file in the left panel and the file you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down menu.

   Step Result: The selected files are opened in the two side-by-side editors. A text editing mode is used to offer a better view of the differences.
2. Click the **Three-Way Comparison** button on the toolbar and select the base file in the **Base** field. You can specify the path by using the text field, the history drop-down, or the browsing tools in the **Browse** drop-down menu.
3. To highlight the differences, click the **Perform File Differencing** button on the toolbar.
4. You can use the drop-down menu on the left side of the toolbar to change the *algorithm* for the operation.
5. You can also use the **Diff Options** button to access the **Files Comparison** preferences page where you can choose to ignore certain types of markup and configure various options.

The resulting comparison will show you differences between the two files, as well as differences between either of them and the base (ancestor) file. The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes.

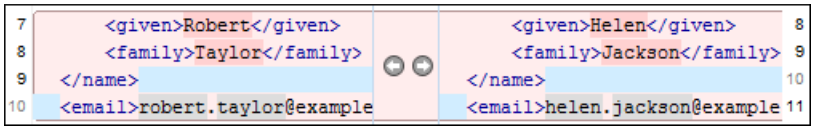

Figure 590: Three-Way Differences

Highlighting Colors

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the ***Files Comparison / Appearance*** *preferences page*, but the default colors and their shades mean the following:

- **Pink** - Identifies blocks of changes that include conflicts.
- **Gray** - Identifies your outgoing changes that do not include conflicts.
- **Blue** - Identifies incoming changes that do not include conflicts.
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Navigate Differences

To navigate through differences, do one of the following:

- Use the navigation buttons on the toolbar (or in the **Compare** menu).
- Select a block of differences by clicking its small colored marker in the overview ruler located in the right-most part of the window. At the top of the overview ruler there is a success indicator that turns green where there are no differences, or red if differences are found.
- Click a colored area in between the two text editors.

Editing Actions

You can edit the files directly in either editing pane. The two editors are constantly synchronized and the differences are refreshed when you save the modified document or when you click the  **Perform File Differencing** button.

A variety of actions are available on the *toolbar* and in the *various menus* (these same actions are also available in the contextual menu in both editing panes). The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

 **Append left change to right and**  **Append right change to left**

Copies the content of the selected change from one side and appends it on the other, according to the content of the corresponding change. As a result, the side where the arrow points to will contain the changes from both sides.

 **Copy change from left to right and**  **Copy change from right to left**

Replaces the content of a change from one side with the content of the corresponding change from the other side.

 **Remove change**

Rejects the change on the particular side and preserves the particular content on the other side.

Three-Way Diff Algorithms

Oxygen XML Editor offers the following three-way diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Second Level Comparisons

For both two-way and three-way comparisons, Oxygen XML Editor automatically performs a second level comparison for the **Lines**, **XML Fast**, and **XML Accurate** algorithms. After the first comparison is finished, the second level comparisons for the **Lines** algorithm is processed on text nodes using a word level comparison, meaning that it looks for identical words. For the **XML Fast** and **XML Accurate** algorithms, the second level

comparison is processed using a *syntax-aware comparison*, meaning that it looks for identical *tokens*. This second level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

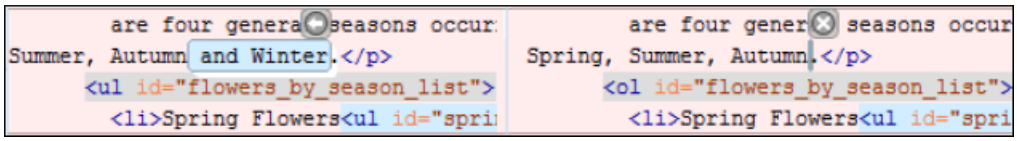

Figure 591: Second Level Diff Comparison

Note: If a modified text fragment contains XML markup (such as processing instructions, XML comments, CData, or elements), the second level comparison will not automatically be performed. In this case you can manually select a second level comparison by doing a word level or character level comparison.

To do a word level comparison, select **Show word level details** from the contextual menu or **Compare** menu.

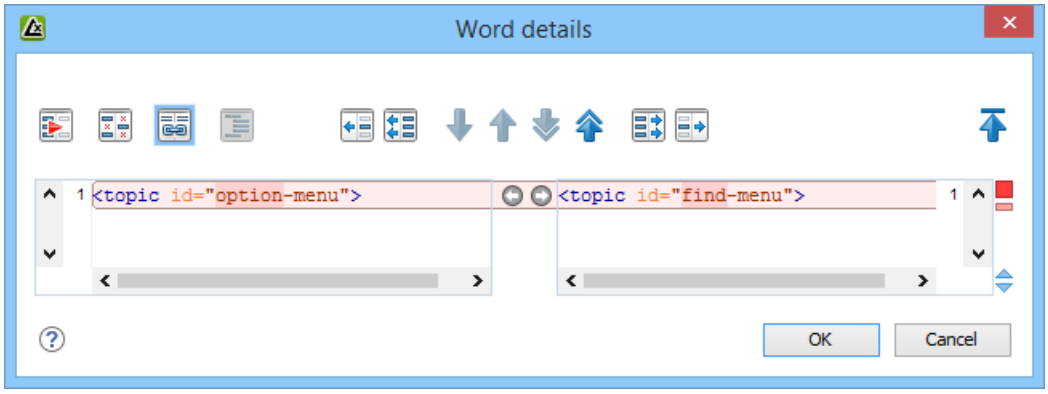

Figure 592: Word Level Comparison

To do a character level comparison, select **Show Character Level details** from the contextual menu or **Compare** menu.

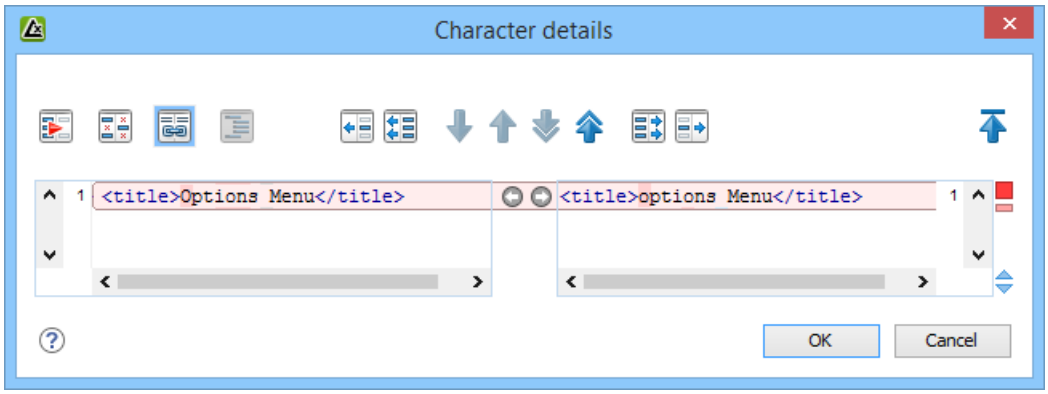

Figure 593: Character Level Comparison

Author Visual Mode

The **Compare Files** tool includes an **Author** mode that displays the files in a visual mode similar to the **Author** editing mode in Oxygen XML Editor/Author. This makes it easier to see how the compared changes will look in the final output. This visual mode is available when the compared files are detected as being XML. To determine whether the files are initially opened in the merge tool's **Text** or **Author** mode, it detects the ***Initial Edit Mode*** *in the Document Type Association configuration* and the mode the files were last opened in Oxygen XML Editor/Author.

Note: This mode is not available if the ***Enable file comparison in Author mode*** *option* is not selected in the **Diff** > **Files Comparison** preferences page.

This visual mode includes unique features such as a ***Tags Display Mode*** *drop-down button* on the toolbar that allows you to select the amount of tags to display in this visual mode. This mode also presents differences that were made using the **Track Changes** feature (although the **Track Changes** feature is not available in the comparison tool).

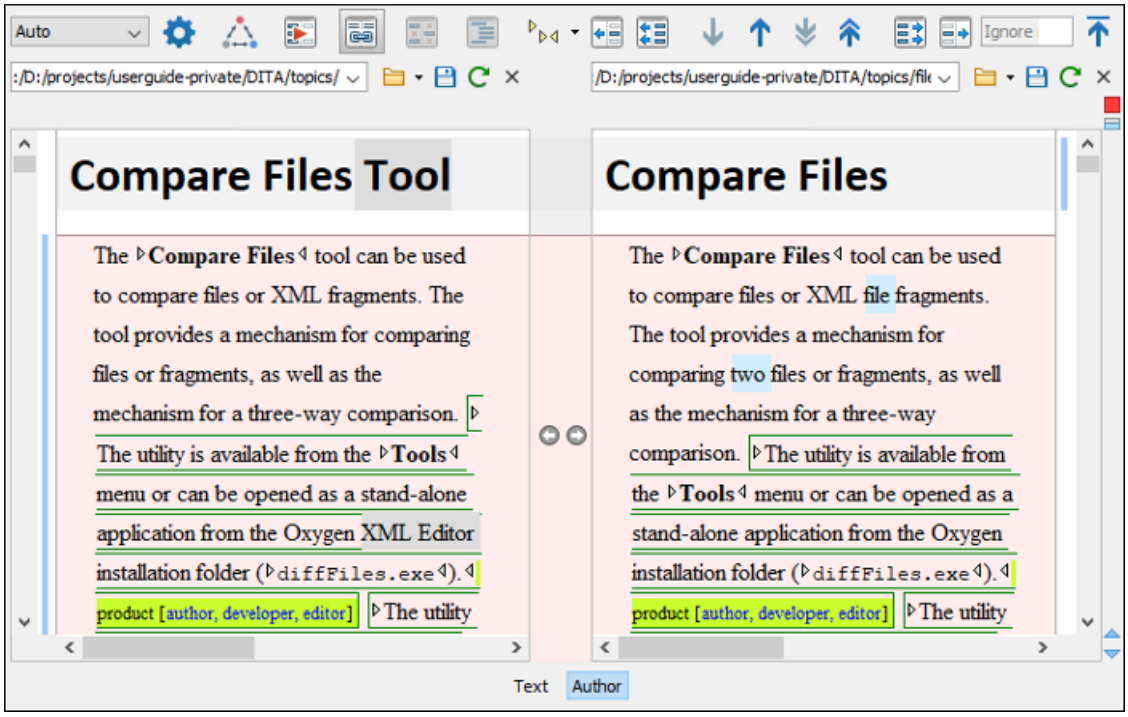

Figure 594: File Comparison Tool - Author Mode

Author Mode Algorithms

The visual **Author** mode offers the following diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Second Level Comparisons

The visual **Author** mode automatically performs a second level comparison for the **XML Fast** and **XML Accurate** algorithms. After the first comparison is finished, the second level comparisons is processed on text nodes using a word level comparison, meaning that it looks for identical words. This second level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

Compare Directories on page 961

Starting File Comparison Tool from a Command Line

The file comparison tool can be started by using command-line arguments. In the installation folder there is an executable shell (`diffFiles.bat` on Windows, `diffFiles.sh` on OS X and Linux). To specify the files to compare, you can pass command-line arguments using the following construct: `diffFiles.bat/diffFiles.sh [path to left file] [path to right file] [path to 3-way base file]`.

If three files are specified, the tool will start in the *3-way comparison mode*. If only two files are specified, the tool will start in the *2-way comparison mode*. The first specified file will be added to the left panel in the comparison

tool, the second file to the right panel, and the optional third file will be the base (ancestor) file used for a 3-way comparison. If you pass only one argument, you are prompted to manually choose another file.

If you want to launch the file comparison tool from an external application with specified files and you want the file browsing tools at the top of both panels to be hidden, you should use the `-ext` argument as the first command. There are some additional arguments that are allowed and to see all the details for the command line construct, type `diffFiles.bat --help` in the command line.

Example:

To do a 3-way comparison, the command line might look like this:

Windows

```
diffFiles.bat "c:\docs\file 1" "c:\docs\file 2" c:\docs\basefile
```

Tip: If there are spaces in the path names, surround the paths with quotes.

Linux

```
diffFiles.sh home/file1 home/file2 home/basefile
```

Mac OS X

```
diffFiles.sh documents/file1 documents/file2 documents/basefile
```

How to Integrate the File Comparison Tool with Git

The file comparison tool can be integrated with Git clients. It requires that you configure your `.gitconfig` file and then you can simply start the tool from the command line.

To integrate the **Compare Files** tool with your Git client, follow this procedure:

1. Use one of the following methods to instruct your Git client to use the Oxygen **Compare Files** tool:
   - **Manual Configuration** - Locate your Git user-specific configuration file (`.gitconfig`) and edit it with a text editor (for example, in Windows, the `.gitconfig` file is most likely located in your user home directory). Add (or replace) the following lines:

     ```
     [diff]
         tool = oxygendiff
     [merge]
         tool = oxygendiff
     [difftool "oxygendiff"]
         cmd = '[pathToOxygenInstallDir]/diffFiles.exe' -ext $REMOTE $LOCAL $LOCAL
     [mergetool "oxygendiff"]
         cmd = '[pathToOxygenInstallDir]/diffFiles.exe' -ext $LOCAL $REMOTE $BASE $MERGED
         trustExitCode = true
     [difftool]
         prompt = false
     ```

     Note: For Mac OS X, the **cmd** lines would start with something like: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**. For Linux, the **cmd** lines would start with something like: **sh "/Oxygen XML Editor/diffFiles.sh"**.
   - **Command Line Configuration** - To automatically configure the `.gitconfig` file, you can run the following commands from a command line:

     ```
     git config --global diff.tool oxygendiff
     git config --global difftool.oxygendiff.cmd '[Oxygen install dir]/diffFiles.exe -ext
     $REMOTE $LOCAL $LOCAL'
     git config --global merge.tool oxygendiff
     git config --global mergetool.oxygendiff.cmd '[Oxygen install dir]/diffFiles.exe
     -ext $LOCAL $REMOTE $BASE $MERGED'
     git config --global mergetool.oxygendiff.trustExitCode true
     ```

     Note: For Mac OS X, the Oxygen file comparison tool would be specified in the second and fourth commands with something like: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**. For Linux, it would be something like: **sh "/Oxygen XML Editor/diffFiles.sh"**.
2. To start the **Compare Files** tool and see a comparison of changes for a particular file, run the following command from a command line:

   ```
   git difftool [PathToFile]
   ```

Tip: If the file you want to compare has conflicts, you can start the **Compare Files** tool as a *merge conflict resolution* tool by running the following command:

```
git mergetool [PathToFile]
```

For more information about the Git *difftool* syntax, see *https://git-scm.com/docs/git-difftool*.

For more information about the Git *mergetool* syntax, see *https://git-scm.com/docs/git-mergetool*.

How to Integrate the File Comparison Tool with SourceTree

The file comparison tool can be integrated with SourceTree so that you can use it to compare changes. The advantages of doing this include:

- The Oxygen **Compare Files** tool presents the files side-by-side and makes it much easier to determine real changes.
- The Oxygen **Compare Files** tool includes XML comparison algorithms.
- The Oxygen **Compare Files** tool includes various options for configuring the comparison.
- The Oxygen **Compare Files** tool allows you to navigate through changes.

To integrate the **Compare Files** tool with SourceTree, follow this procedure, depending on your operating system:

Windows

1. In SourceTree, go to **Tools** > **Options**.
2. Go to the **Diff** tab.
3. In the **External Diff/Merge** section, configure the settings as follows:
   - **External Diff Tool** - Select **Custom**.
   - **Diff Command** - Enter the path of the Oxygen `diffFile.exe` file (for example: `c:\Programs\Oxygen XML Editor 19\diffFiles.exe`).
   - **Arguments** - Enter **-ext $REMOTE $LOCAL $LOCAL**.
   - **Merge Tool** - Select **Custom**.
   - **Diff Command** - Enter the path of the Oxygen `diffFile.exe` file (for example: `c:\Programs\Oxygen XML Editor 19\diffFiles.exe`).
   - **Arguments** - Enter **-ext $LOCAL $REMOTE $BASE $MERGED**.
4. Click **OK**.

   Result: In SourceTree, you can now compare file changes with the Oxygen **Compare Files** tool by simply selecting **External Diff** from the contextual menu, **Actions** menu, or **Ctrl+D**.

Mac OS X

1. In SourceTree, go to **SourceTree** > **Preferences**.
2. Go to the **Diff** tab.
3. In the **External Diff/Merge** section, configure the settings as follows:
   - **External Diff Tool** - Select **Custom**.
   - **Diff Command** - Enter a command line argument to launch the Oxygen `diffFiles.sh` file (for example: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**).
   - **Arguments** - Enter **-ext $REMOTE $LOCAL $LOCAL**.
   - **Merge Tool** - Select **Custom**.
   - **Diff Command** - Enter a command line argument to launch the Oxygen `diffFiles.sh` file (for example: **sh "/Applications/Oxygen XML Editor/diffFiles.sh"**).
   - **Arguments** - Enter **-ext $LOCAL $REMOTE $BASE $MERGED**.
4. Close the preferences dialog box.

   Result: In SourceTree, you can now compare file changes with the Oxygen **Compare Files** tool by simply selecting **External Diff** from the contextual menu or **Actions** menu.

Toolbar and Contextual Menu Actions of the Compare Files Tool

The toolbar of the **Compare Files** tool contains operations that can be performed on the source and target files or XML fragments. Many of the actions are also available in the contextual menu.

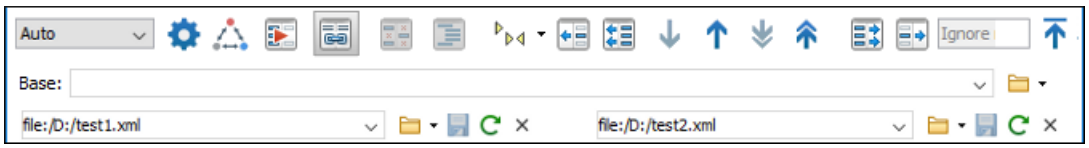

Figure 595: Compare Toolbar

The following actions are available:

Algorithm

This drop-down menu allows you to select one of the following diff algorithms (depending on whether it is a two-way or three-way comparison):

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Characters** - Computes the differences at character level, meaning that it compares two files or fragments looking for identical characters. This algorithm is not available when the file comparison is in **Author** mode.
- **Words** - Computes the differences at word level, meaning that it compares two files or fragments looking for identical words. This algorithm is not available when the file comparison is in **Author** mode.
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **Syntax Aware** - Computes differences for the file types or fragments known by Oxygen XML Editor, taking the syntax (the specific types of tokens) into consideration. This algorithm is not available when the file comparison is in **Author** mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Diff Options

Opens the ***Files Comparison*** *preferences page* where you can configure various options.

Three-Way Comparison

Toggle action that allows you to perform a three-way comparison between the two files displayed in the two editing panes and a base (ancestor) file.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Synchronized scrolling

Toggles synchronized scrolling on or off so that a selected difference can be seen on both sides of the application window. This option is on by default.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces. This option is not available when the file comparison is in **Author** mode.

Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on OS X))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences. This option is not available when the file comparison is in **Author** mode.

Note: When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Tags Display Mode

Allows you to select the amount of markup to be displayed in the ***Author*** *visual mode*. You can choose between: **Full Tags with Attributes**, **Full Tags**, **Block Tags**, **Inline Tags**, **Partial Tags**, or **No Tags**.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Copy All Changes from Left to Right

Copies all changes from the file in the left panel to the file in the right panel.

Copy Change from Left to Right

Copies the selected difference from the file in the left panel to the file in the right panel.

Ignore Nodes by XPath

You can use this text field to enter an *XPath expression* to ignore certain nodes from the comparison. It will be processed as XPath version 2.0. You can also enter the name of the node to ignore all nodes with the specified name (for example, if you want to ignore all ID attributes from the document, you could simply enter `@id`). This field is only available when comparing XML documents using the **XML Fast** or **XML Accurate** algorithms.

Note: If an XPath expression is specified in the ***Ignore nodes by XPath*** *option* in the **Diff / File Comparison** preferences page, that one is used as a default when the application is started. If you then enter an expression in this field on the toolbar, this one will be used instead of the default. If you delete the expression from this field, neither will be used.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Base

Available for *three-way comparisons*. It is the base file that will be compared with the files opened in the left and right editors. You can specify the path to the file by using the text field, its history drop-down, or the browsing tools in the **Browse** drop-down menu.

Left-Side (Source) File

You can specify the path to the file to be compared on the left side (source) by using the text field, its history drop-down, or the browsing tools in the **Browse** drop-down menu.

Save

Saves the changes made in the source (left-side) file.

Reload

Reloads the source (left-side) file.

Close

Closes the source (left-side) file.

Right-Side (Target) File

You can specify the path to the file to be compared on the right side (target) by using the text field, its history drop-down, or the browsing tools in the **Browse** drop-down menu.

Save

Saves the target (right-side) file.

Reload

Reloads the target (right-side) file.

Close

Closes the target (right-side) file.

Compare Files Tool Menus

The menus in the **Compare Files** tool contain some of the same actions that are on the toolbar, as well as some common actions that are identical to the same actions in the Oxygen XML Editor menus. The menu actions include:

File Menu

Source > Open

Browses for a file that will be displayed in the left panel.

Source > Open URL

Browses for a remote file that will be displayed in the left panel.

Source > Open File from Archive

Browses an archive for a file that will be displayed in the left panel.

Source > Reload

Reloads the file in the left panel.

Source > Save

Saves the changes made to the file in the left panel.

Source > Save As

Allows you to choose a destination to save the file in the left panel.

Source > Close

Closes the file in the left panel.

Target > Open

Browses for a file that will be displayed in the right panel.

Target > Open URL

Browses for a remote file that will be displayed in the right panel.

Target > Open File from Archive
Browses an archive for a file that will be displayed in the right panel.

Target > Reload
Reloads the file in the right panel.

Target > Save
Saves the changes made to the file in the right panel.

Target > Save As
Allows you to choose a destination to save the file in the right panel.

Target > Close
Closes the file in the right panel.

Base > Open
Browses for a file that will be compared with both files in a *three-way comparison*.

Base > Open URL
Browses for a remote file that will be compared with both files in a *three-way comparison*.

Base > Open File from Archive
Browses an archive for a file that will be compared with both files in a *three-way comparison*.

Close (Ctrl + W (Command + W on OS X))
Closes the application.

Edit Menu

Cut
Cut the selection from the currently focused editor panel to the clipboard.

Copy
Copy the selection from the currently focused editor panel to the clipboard.

Paste
Paste content from the clipboard into the currently focused editor panel.

Select all
Selects all content in the currently focused editor panel.

Undo
Undo changes in the currently focused editor panel.

Redo
Redo changes in the currently focused editor panel.

Find Menu

Find/Replace
Perform *find/replace* operations in the currently focused editor panel.

Find Next
Go to the next match using the same options as the last *find* operation. This action runs in both editor panels.

Find Previous
Go to the previous match using the same options as the last *find* operation. This action runs in both editor panels.

Compare Menu

Three-Way Comparison

Toggle action that allows you to perform a three-way comparison between the two files displayed in the two editing panes and a base (ancestor) file.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

Last Change (Ctrl + E (Command + E on OS X))

Jumps to the last change.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Copy All Changes from Left to Right

Copies all changes from the file in the left panel to the file in the right panel.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy Change from Left to Right

Copies the selected difference from the file in the left panel to the file in the right panel.

Show Word Level Details

Provides a word-level comparison of the selected change.

Show Character Level Details

Provides a character-level comparison of the selected change.

Format and Indent Both Files (Ctrl + Shift + P (Command + Shift + P on OS X))

Formats and indents both files before comparing them. Use this option for comparisons that contain long lines that make it difficult to spot differences.

Note: When comparing two JSON files, the **Format and Indent Both Files** action will automatically sort the keys in both files the same to make it easier to compare.

Options Menu

Preferences

Opens the preferences dialog box that includes numerous pages of options that can be configured.

Menu Shortcut Keys

Opens the **Menu Shortcut Keys** option page where you can configure keyboard shortcuts available for menu items.

Reset Global Options

Resets options to their default values. Note that this option appears only when the tool is executed as a stand-alone application.

Import Global Options

Allows you to import an options set that you have previously exported.

Export Global Options

Allows you to export the current options set to a file.

Help Menu

Help (F1)

Opens a **Help** dialog box that displays the User Manual at a section that is appropriate for the context of the current cursor position.

Use Online Help

If this option is selected, when you select Help or press F1 while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Report problem

Opens a dialog box that allows the user to write the description of a problem that was encountered while using the application. You can change the URL where the reported problem is sent by using the `com.oxygenxml.report.problems.url` system property. The report is sent in XML format through the `report` parameter of the POST HTTP method.

Support Center

Opens the Oxygen XML Editor Support Center web page in a browser.

Compare Directories

The **Compare Directories** tool can be used to compare and manage changes to files and folders within the structure of your directories. The utility is available from the **Tools** menu or can be opened as a stand-alone application from the Oxygen XML Editor installation folder (`diffDirs.exe`).

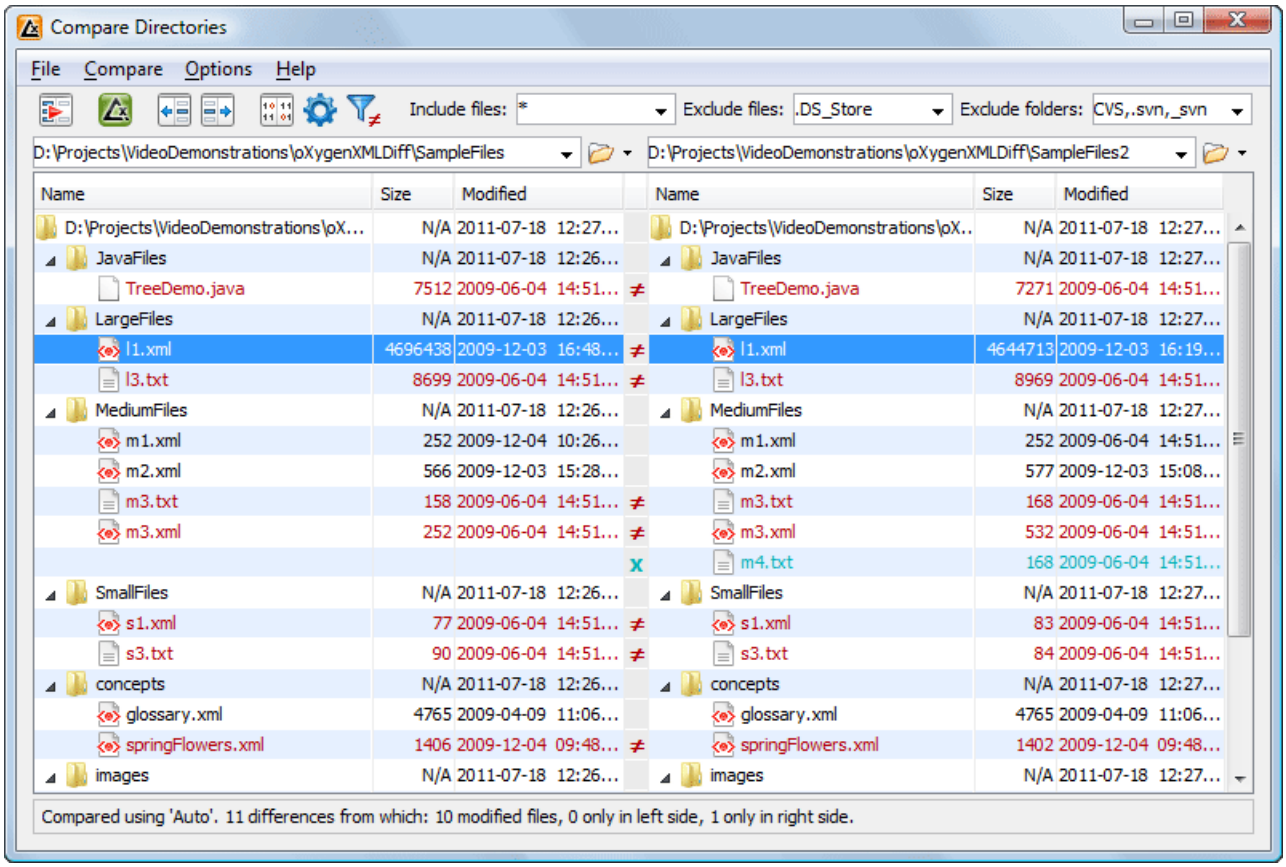

Figure 596: Compare Directories Tool

Starting the Tool from a Command Line

The directory comparison tool can also be started by using command-line arguments. In the installation folder there is an executable shell (`diffDirs.bat` on Windows, `diffDirs.sh` on OS X and Linux). To specify the directories to compare, you can pass command-line arguments using the following construct: `diffDirs.bat/diffDirs.sh [directory path 1] [directory path 2]`.

If you pass only one argument, you are prompted to manually choose the second directory or archive.

Example:

To do a comparison between two directories, the command line would look like this:

Windows

```
diffDirs.bat "c:\documents new" "c:\documents old"
```

Tip: If there are spaces in the path names, surround the paths with quotes.

Linux

```
diffDirs.sh home/documents1 home/documents2
```

Mac OS X

```
diffDirs.sh documents1 documents2
```

Directory Comparisons

To perform a directory comparison, follow these steps:

1. Select a folder in the left panel and the folder you want to compare it to in the right panel. You can specify the path by using the text field, the history drop-down, or the **Browse for local directory** action in the **Browse** drop-down menu.

Step Result: The selected directory structures are opened in the two side-by-side panels.

2. To highlight the differences between the two folders, click the **Perform Directories Differencing** button from the toolbar.
3. You can also use the **Diff Options** button to access the ***Directories Comparison*** *preferences page* where you can configure various options.

To compare the content of two archives, follow these steps:

1. Use the **Browse for archive file** action in the **Browse** drop-down menu to select the archives in the left and right panels.
2. By default, the supported archives are not treated as directories and the comparison is not performed on the files inside them. To make Oxygen XML Editor treat supported archives as directories, select the ***Look in archives*** *option* in the **Directories Comparison** preferences page.
3. To highlight the differences, click the **Perform Directories Differencing** button from the toolbar.

The directory comparison results are presented using two tree-like structures showing the files and folders, including their name, size, and modification date. A column that contains graphic symbols separates the two tree-like structures. The graphic symbols can be one of the following:

- An **X** symbol, when a file or a folder exists in only one of the compared directories.
- A ≠symbol, when a file exists in both directories but the content differs. The same sign appears when a collapsed folder contains differing files.

The color used for the symbol and the directory or file name can be customized in the ***Directories Comparison / Appearance*** *preferences page*. You can double-click lines marked with the ≠ symbol to open a **Compare Files** window, which shows the differences between the two files.

The directories that contain files that differ are expanded automatically so that you can focus directly on the differences. You can merge the contents of the directories by using the copy actions. If you double-click (or press **Enter**) on a line with a pair of files, Oxygen XML Editor starts a *file comparison* between the two files, using the **Compare Files** tool.

Related Information:

Compare Files on page 1646

Toolbar and Contextual Menu Actions of the Compare Directories Tool

The toolbar of the **Compare Directories** tool contains operations that can be performed on the compared directory structure. Some of the toolbar actions are also available in the contextual menu.

Figure 597: Compare toolbar

Toolbar Actions

Perform Directories Differencing

Looks for differences between the two directories displayed in the left and right side of the application window.

Perform Files Differencing

Opens the ***Compare Files*** *tool* that allows you to compare the currently selected files.

Copy Change from Right to Left

Copies the selected change from the right side to the left side (if there is no file/folder in the right side, the left file/folder is deleted).

 **Copy Change from Left to Right**

Copies the selected change from the left side to the right side (if there is no file/folder in the left side, the right file/folder is deleted).

 **Binary Compare**

Performs a byte-level comparison on the selected files.

 **Diff Options**

Opens the ***Directory Comparison*** *preferences page* where you can configure various options.

 **Show Only Modifications**

Displays a more uncluttered file structure by hiding all identical files.

File and folder filters

Differences can be filtered using three combo boxes: **Include files**, **Exclude files**, and **Exclude folders**. They come with predefined values and are editable to allow custom values. All of them accept multiple comma-separated values and the ***** and **?** wildcards. For example, to filter out all JPEG and GIF image files, edit the **Exclude files** filter box to read **`*.jpeg, *.png`**. Each filter includes a drop-down menu with the latest 15 filters applied.

Contextual Menu Actions

 **Perform Files Differencing**

Opens the ***Compare Files*** *tool* that allows you to compare the currently selected files.

 **Binary Compare**

Performs a byte-level comparison on the selected files.

 **Copy Change from Right to Left**

Copies the selected difference from the file in the right panel to the file in the left panel.

 **Copy Change from Left to Right**

Copies the selected difference from the file in the left panel to the file in the right panel.

Open

If the action is invoked on a file, the selected file is opened in Oxygen XML Editor. If the action is invoked on a directory, the selected directory is opened in the default file browser for your particular operating system.

Open in System Application

Opens the selected file in the system application that is associated with that type of file. The action is available when launching the **Compare Directories** tool from the **Tools** menu in Oxygen XML Editor.

Show in Explorer

Opens the default file browser for your particular operating system with the selected file highlighted.

Compare Directories Tool Menus

The menus in the **Compare Directories** tool contain some of the same actions that are on the toolbar, as well as some common actions that are identical to the same actions in the Oxygen XML Editor menus. The menu actions include:

File Menu

Close (Ctrl + W (Command + W on OS X))

Closes the application.

Compare Menu

Perform Directories Differencing

Looks for differences between the two directories displayed in the left and right side of the application window.

Perform Files Differencing

Opens the ***Compare Files*** *tool* that allows you to compare the currently selected files.

Copy Change from Right to Left

Copies the selected change from the right side to the left side (if there is no file/folder in the right side, the left file/folder is deleted).

Copy Change from Left to Right

Copies the selected change from the left side to the right side (if there is no file/folder in the left side, the right file/folder is deleted).

Options Menu

Preferences

Opens the preferences dialog box that includes numerous pages of options that can be configured.

Menu Shortcut Keys

Opens the **Menu Shortcut Keys** option page where you can configure keyboard shortcuts available for menu items.

Reset Global Options

Resets options to their default values. Note that this option appears only when the tool is executed as a stand-alone application.

Import Global Options

Allows you to import an options set that you have previously exported.

Export Global Options

Allows you to export the current options set to a file.

Help Menu

Help (F1)

Opens a **Help** dialog box that displays the User Manual at a section that is appropriate for the context of the current cursor position.

Use Online Help

If this option is selected, when you select Help or press F1 while hovering over any part of the interface, Oxygen XML Editor attempts to open the help documentation in online mode. If this option is not selected or an internet connection fails, the help documentation is opened in offline mode.

Report problem

Opens a dialog box that allows the user to write the description of a problem that was encountered while using the application. You can change the URL where the reported problem is sent by using the `com.oxygenxml.report.problems.url` system property. The report is sent in XML format through the `report` parameter of the POST HTTP method.

Support Center

Opens the Oxygen XML Editor Support Center web page in a browser.

Compare Images

You can use the **Compare Directories** tool to compare images. If you double-click a line that contains two different images, the **Compare images** window is displayed. This dialog box presents the images in the left and right sides, scaled to fit the available view area. You can use the contextual menu actions to scale the images to their original size or scale them down to fit in the view area.

The supported image types are: *GIF*, *JPG*, *JPEG*, *PNG*, and *BMP*.

Compare Directories Against a Base (3-Way)

The **Compare Directories Against a Base (3-way)** tool allows you to perform three-way comparisons on directories to help you identify and merge changes between multiple modifications of the same directory structure. It is especially helpful for teams that have multiple authors contributing documents to the same directory system. It offers information about conflicts and changes, and includes actions to easily merge, accept, overwrite, or ignore changes to the directory system.

How to Perform 3-Way Directory Comparisons

To perform a 3-way directories comparison, follow these steps:

1. Select **Compare Directories Against a Base (3-way)** from the **Tools** menu.

   Step Result: This opens a dialog box that allows you to select the 3 file sets that will be used for the comparison.

   Figure 598: Compare Directories Against a Base File Set Chooser

2. Select the file sets to be compared:
   - **Base directory** - This is the original (base) file set before any modifications were made by your or others.
   - **Directory with your changes** - This is the file set with changes that you have made. This file set will be displayed in the left panel in the comparison tool.
   - **Directory with changes made by others** - This is the file set with changes made by others that you want to merge with your changes. This file set will be displayed in the right panel in the comparison tool.
3. Click the **Compare** button to compare the file sets and open the comparison and merge tool.
4. Use the features and actions described in the next section to identify and merge the changes.

3-Way Directory Comparison and Merge Tool

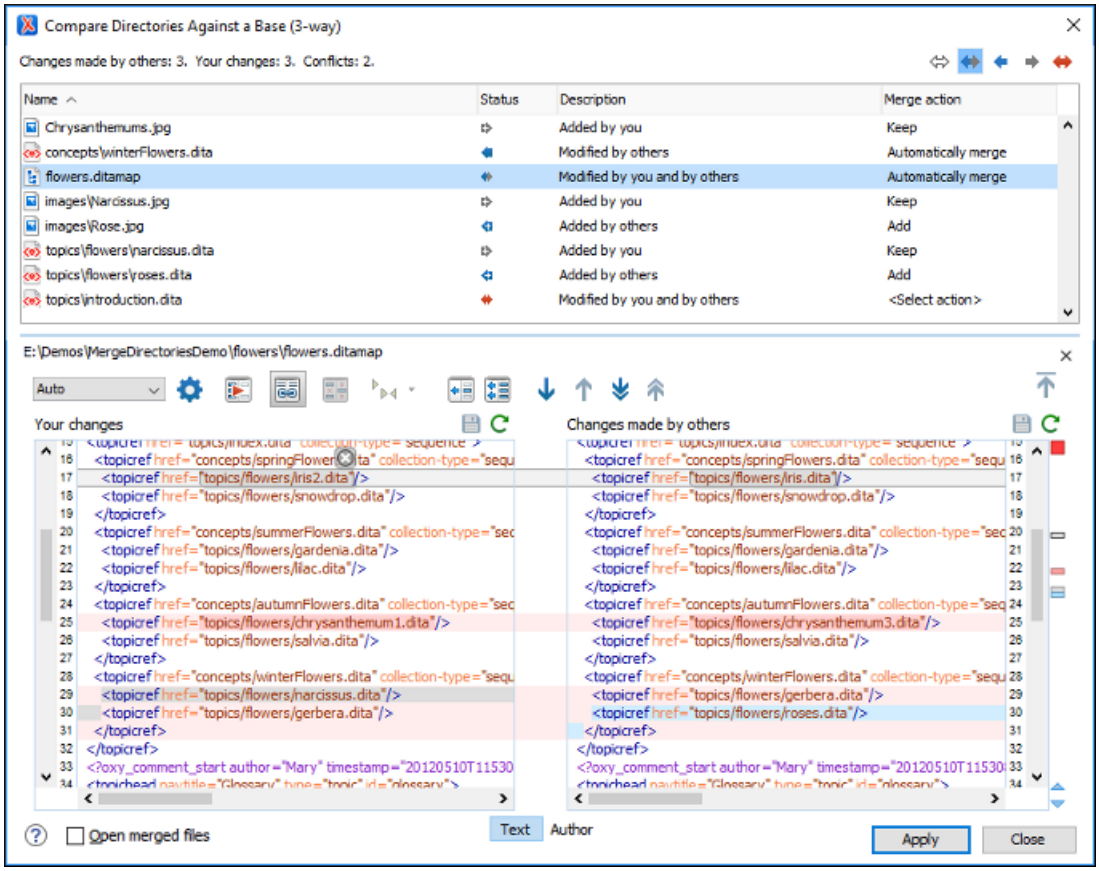

Figure 599: Comparison and Merge Tool

The 3-way directory comparison and merge tool includes the following information, features, and actions:

Number of Changes and Conflicts

The first thing you see in top-left corner of the tool is grand total of all the changes made by others, changes made by you, and the number of conflicts.

Filter Buttons

In the top-right corner you can use the toggle buttons to filter the list of modifications:

Show all files

Use this button to show all modified and unmodified files, as well as conflicts.

Show only files modified by you and others

Filters the list to show all files that have been modified, including conflicts.

Show only files modified by others

Filters the list to only show the files that were modified by others.

Show only files modified by you

Filters the list to only show the files that were modified by you.

Show only conflicting files

Filters the list to only show files that contain conflicts.

List of Files Panel

This panel shows the list of files in the compared file sets based upon the filter button that is selected. This panel includes the following sortable columns:

- **Name** - The file names.

- **Status** - An icon that represents the file status. Red icons indicate some sort of conflict. Gray icons indicate modifications made by you. Blue icons indicate modifications made by others.
- **Description** - A description of the file status.
- **Merge Action** - This column provides a drop-down menu for each file that allows you to choose some merge actions depending upon its status. A default action is always set to automatically merge the changes made by others with your changes. If there is a conflict, the default is **<Select action>** and you are required to make a selection. Click this column to access the drop-down menu where you can make a selection. The same actions are available in the contextual menu.

You can click a file to open it in the file comparison panel (the file from your file set is shown in the left panel while the file from the file set with changes made by others is shown in the right panel). For image files, the comparison panel shows a preview of the image. For other binary files, a preview is not available and you will just see its status.

File Comparison Panels

If you click a file in the top panel, the file is opened in this file comparison section. The file from your file set is shown in the left panel and the file from the other file set is shown in the right panel.

Note: If Oxygen XML Editor does not recognize the file type, a dialog box will be displayed that allows you to select the type of editor you want it to be associated with for this comparison (if you want Oxygen XML Editor to remember this association, you can select the **Associate file type with editor** option at the bottom of the dialog box).

This panel includes the following information and toolbar actions:

File Path

The first thing you see in this panel is the file path where merge actions will be applied if you make changes.

Close

Closes the file comparison panel.

Algorithm Drop-Down Menu

This drop-down menu allows you to select one of the following diff algorithms to be used for file comparisons:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **Lines** - Computes the differences at line level, meaning that it compares two files or fragments looking for identical lines of text. This algorithm is not available when the file comparison is in **Author** mode.
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Diff Options

Opens the ***Files Comparison*** *preferences page* where you can configure various options.

Perform Files Differencing

Looks for differences between the two files displayed in the left and right side panels.

Synchronized scrolling

Toggles synchronized scrolling. When toggled on, a selected difference can be seen in both panels.

Ignore Whitespaces

Enables or disables the whitespace ignoring feature. Ignoring whitespace means that before performing the comparison, the application normalizes the content and trims its leading and trailing whitespaces. This option is not available when the file comparison is in **Author** mode.

Tags Display Mode

Allows you to select the amount of markup to be displayed in the **Author** visual mode. You can choose between: **Full Tags with Attributes**, **Full Tags**, **Block Tags**, **Inline Tags**, **Partial Tags**, or **No Tags**.

Copy Change from Right to Left

Copies the selected difference from the file in the right panel to the file in the left panel.

Copy All Changes from Right to Left

Copies all changes from the file in the right panel to the file in the left panel.

Next Block of Changes (Ctrl + Period (Command + Period on OS X))

Jumps to the next block of changes. This action is not available when the cursor is positioned on the last change block or when there are no changes.

Note: A change block groups one or more consecutive lines that contain at least one change.

Previous Block of Changes (Ctrl + Comma (Command + Comma on OS X))

Jumps to the previous block of changes. This action is not available when the cursor is positioned on the first change block or when there are no changes.

Next Change (Ctrl + Shift + Period (Command + Shift + Period on OS X))

Jumps to the next change from the current block of changes. When the last change from the current block of changes is reached, it highlights the next block of changes. This action is not available when the cursor is positioned on the last change or when there are no changes.

Previous Change (Ctrl + Shift + Comma (Command + Shift + M on OS X))

Jumps to the previous change from the current block of changes. When the first change from the current block of changes is reached, it highlights the previous block of changes. This action is not available when the cursor is positioned on the first change or when there are no changes.

First Change (Ctrl + B (Command + B on OS X))

Jumps to the first change.

Left-Side File (Your changes)

Above the panel you can see the file path and the following two buttons:

Save

Saves changes made to the file.

Reload

Reloads the file.

Right-Side File (Changes made by others)

Above the panel you can see the file path and the following two buttons:

Reload

Reloads the file.

Displaying Changes in the File Comparison Panels

The line numbers on each side and colored marks on the right-side vertical stripe help you to quickly identify the locations of the differences. Adjacent changes are grouped into blocks of changes.

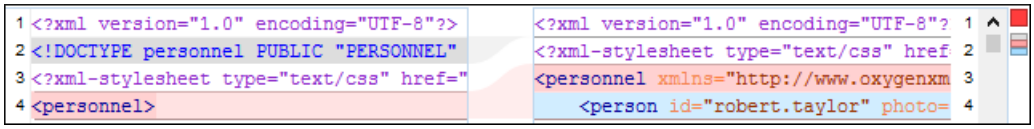

Figure 600: File Comparison Panels

The differences are also highlighted in several colors, depending on the type of change, and dynamic lines connect the compared fragments in the middle section between the two panes. The highlighting colors can be customized in the ***Files Comparison / Appearance*** *preferences page*, but the default colors and their shades mean the following:

- **Pink** - Identifies modifications on either side.
- **Gray** - Identifies an addition of a node in the left side (your outgoing changes).
- **Blue** - Identifies an addition of a node in the right side (incoming changes).
- **Lighter Shade** - Identifies blocks of changes that can be merged in their entirety.
- **Darker Shade** - Identifies specific changes within the blocks that can be merged more precisely.

Direct Editing Actions in the File Comparison Panels

In addition to selecting merge actions from the drop-down menus in the **Merge Action** column in the top panel, you can also edit the files directly in the left pane (your local changes). The two editors are constantly synchronized and the differences are refreshed when you save the modified document (**Save** button or **Ctrl+S**) or when you click the **Perform File Differencing** button.

A variety of actions are available in the contextual menu in both editing panes. The tool also includes some inline actions to help you merge, copy, or remove changes. When you select a change, the following inline action widgets are available, depending on the type of change:

Append right change to left

Copies the content of the selected change from the right side and appends it on the left side.

Copy change from right to left

Replaces the content of a change in the left side with the content of the change in the right side.

Remove change

Removes the change from the left side.

Any time you save manual changes (**Save** button or **Ctrl+S**), the selection in the **Merge Action** column in the top panel automatically changes to **Use merged** and a copy of the original file is kept so that you can revert to the original file if necessary. To discard your manual changes and revert to your original changes, select a different action in the **Merge Action** drop-down menu.

Open Merged Files

If you select this option, all the files that will be modified by the merge operation will be opened in the editor after the operation is finished.

Applying Changes

When you click the **Apply** button, all the merge actions you have selected and the changes you have made will be processed.

If there are unresolved conflicts (conflicts where no merge action is selected in the **Merge Action** drop-down menu), a dialog box will be displayed that allows you to choose how to solve the conflicts. You can choose between the following:

- **Keep your changes** - If you select this option and then click **Apply**, your local changes will be preserved for the unresolved conflicts.
- **Overwrite your changes** - If you select this option and then click **Apply**, your local changes will be overwritten with the changes made by others, for the unresolved conflicts.
- **Cancel** - You can click the **Cancel** button to go back to the merge tool to resolve the conflicts individually.

Cancelling Changes

If you click the **Cancel** button at the bottom of the merge tool, all the changes you made in the tool will be lost.

Author Visual Mode

The **Comparison and Merge** tool includes an **Author** mode that displays the files in a visual mode similar to the **Author** editing mode in Oxygen XML Editor/Author. This makes it easier to see how the compared changes will look in the final output. This visual mode is available when the compared files are detected as being XML. To

determine whether the files are initially opened in the merge tool's **Text** or **Author** mode, it detects the ***Initial Edit Mode*** *in the Document Type Association configuration* and the mode the files were last opened in Oxygen XML Editor/Author.

Note: This mode is not available if the ***Enable file comparison in Author mode*** *option* is not selected in the **Diff** > **Files Comparison** preferences page.

This visual mode includes unique features such as a ***Tags Display Mode*** *drop-down button* on the toolbar that allows you to select the amount of tags to display in this visual mode. This mode also presents differences that were made using the **Track Changes** feature (although the **Track Changes** feature is not available in the comparison tool).

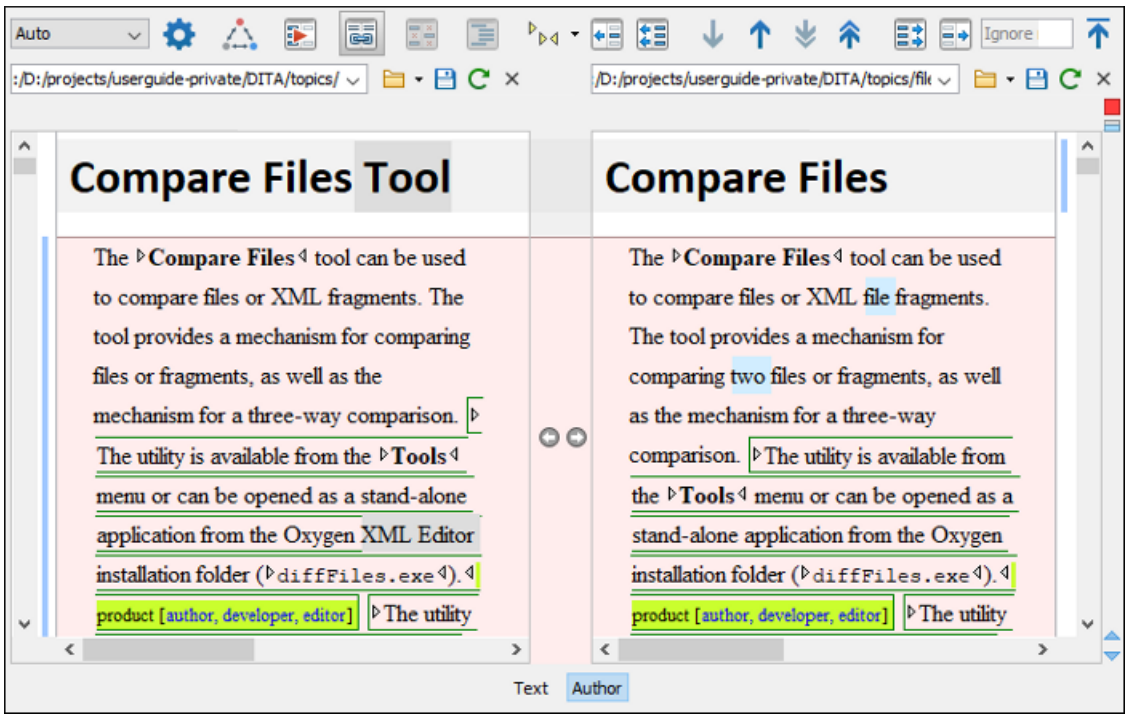

Figure 601: File Comparison Tool - Author Mode

Author Mode Algorithms

The visual **Author** mode offers the following diff algorithms to compare files:

- **Auto** - Selects the most appropriate algorithm, based on the compared content and its size (selected by default).
- **XML Fast** - Comparison that works well on large files or fragments, but it is less precise than **XML Accurate**.
- **XML Accurate** - Comparison that is more precise than **XML Fast**, at the expense of speed. It compares two XML files or fragments looking for identical XML nodes.

Author Mode Second Level Comparisons

The visual **Author** mode automatically performs a second level comparison for the **XML Fast** and **XML Accurate** algorithms. After the first comparison is finished, the second level comparisons is processed on text nodes using a word level comparison, meaning that it looks for identical words. This second level comparison makes it easier to spot precise differences and you can merge or reject the precise modifications.

Document Types and Frameworks

8

Topics:

- *Predefined Document Types (Frameworks)*
- *Other Supported Document Types*

A *framework* is associated to an XML document type according to a set of rules. It also includes a variety of settings that improve editing capabilities in the **Author** mode for its particular file type. These settings include:

- A default grammar used for validation and content completion in both **Author** mode and **Text** mode.
- CSS stylesheets for rendering XML documents in **Author** mode.
- User actions invoked from toolbars or menus in **Author** mode.
- Predefined scenarios used for transformations for the class of XML documents defined by the document type.
- *XML Catalogs*.
- Directories with file templates.
- User-defined extensions for customizing the interaction with the content author in **Author** mode.

Oxygen XML Editor includes built-in support for many common document types. Each *document type is defined in a framework*. You can *create new frameworks or make changes to existing frameworks* to suit your individual requirements.

For more information about configuring a *framework* in Oxygen XML Editor, watch our video:

Related Information:

Advanced Framework Customization on page 1385
Document Type Configuration Dialog Box on page 60

Predefined Document Types (Frameworks)

Oxygen XML Editor includes a variety of specialized editors, views, and features that are dynamic according to the type of document that you open or create. The type of documents that are supported include the most popular predefined XML *frameworks* that include a full set of features as well as other document types that include more generic or common features.

Predefined Frameworks

The following predefined document types (*frameworks*) are fully supported in Oxygen XML Editor and each of these document types include built-in transformation scenarios, validation, content completion, file templates , default CSS files for rendering content in **Author** mode, and default actions for editing in **Author** mode:

- *DocBook 4* - A document type standard for books, articles, and other prose documents (particularly technical documentation).
- *DocBook 5* - An enhanced (version 5) document type standard designed for a variety of documents (particularly technical documentation).
- *DITA* - An XML-based architecture designed for authoring, producing, and delivering technical information.
- *DITA Map* - A document type that collects and organizes references to DITA topics or other maps.
- *XHTML* - Extensible HyperText Markup Language includes the same depth of expression as HTML, but also conforms to XML syntax.
- *TEI ODD* - Text Encoding Initiative One Document Does it all is an XML-conformant specification that allows you to create TEI P5 schema in a literate programming style.

- *TEI P5* - The Text Encoding Initiative guidelines is a standard for the academic community that collectively define an XML format for text that is primarily semantic rather than presentational.
- *JATS* - The NISO Journal Article Tag Suite is a technical standard that defines an XML format for scientific literature.

Advanced Framework Customization on page 1385
Document Type Association Preferences on page 58

DocBook 4 Document Type (Framework)

DocBook is a very popular set of tags for describing books, articles, and other prose documents, particularly technical documentation. DocBook provides a vast number of semantic element tags, divided into three broad categories: structural, *block-level*, and *inline*. DocBook content can then be published in a variety of formats, including HTML, PDF, WebHelp, and EPUB.

File Definition

A file is considered to be a *DocBook 4* document when one of the following conditions are true:

- The root element name is book or `article`.
- The PUBLIC ID of the document contains the string `-//OASIS//DTD DocBook XML`.

Default Document Templates

There are a variety of default *DocBook 4* templates available when creating *new documents from templates* and they can be found in: **Framework Templates** > **DocBook 4**.

The default templates for DocBook 4 documents are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/templates/Docbook 4` folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected in the DocBook 4 file is `docbookxi.dtd` and it is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/4.5/dtd/`.

Default CSS

The default CSS files used for rendering DocBook content in **Author** mode are stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalog

The default *XML Catalog*, `catalog.xml`, is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/`.

Transformation Scenarios

Oxygen XML Editor includes numerous built-in DocBook transformation scenarios that allow you to transform DocBook 4 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. For more information, see the *DocBook 4 Transformation Scenarios* on page 980 section.

Adding Tables in DocBook on page 596

DocBook 4 Author Mode Actions

A variety of actions are available in the DocBook 4 *framework* that can be added to the **DocBook4** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

DocBook 4 Toolbar Actions

The following default actions are readily available on the **DocBook (Author Custom Actions)** toolbar when editing in **Author** mode (by default, most of them are also available in the **DocBook4** menu and in various submenus of the contextual menu):

Bold

Emphasizes the selected text by surrounding it with `<emphasis role="bold">` tag. You can use this action on multiple non-contiguous selections.

Italic

Emphasizes the selected text by surrounding it with `<emphasis role="italic">` tag. You can use this action on multiple non-contiguous selections.

Underline

Emphasizes the selected text by surrounding it with `<emphasis role="underline">` tag. You can use this action on multiple non-contiguous selections.

Link Actions Drop-Down Menu

The following link actions are available from this menu:

Cross reference (link)

Opens a dialog box that allows you to select a target to insert as a hypertext link.

Cross reference (xref)

Inserts a cross reference to other parts of the document.

Web Link (ulink)

Inserts a link that addresses its target with a URL (Universal Resource Locator).

Insert OLink

Opens an **OLink** dialog box that allows you to insert a link that addresses its target indirectly, using the `targetdoc` and `targetptr` values that are present in a ***Targetset*** file.

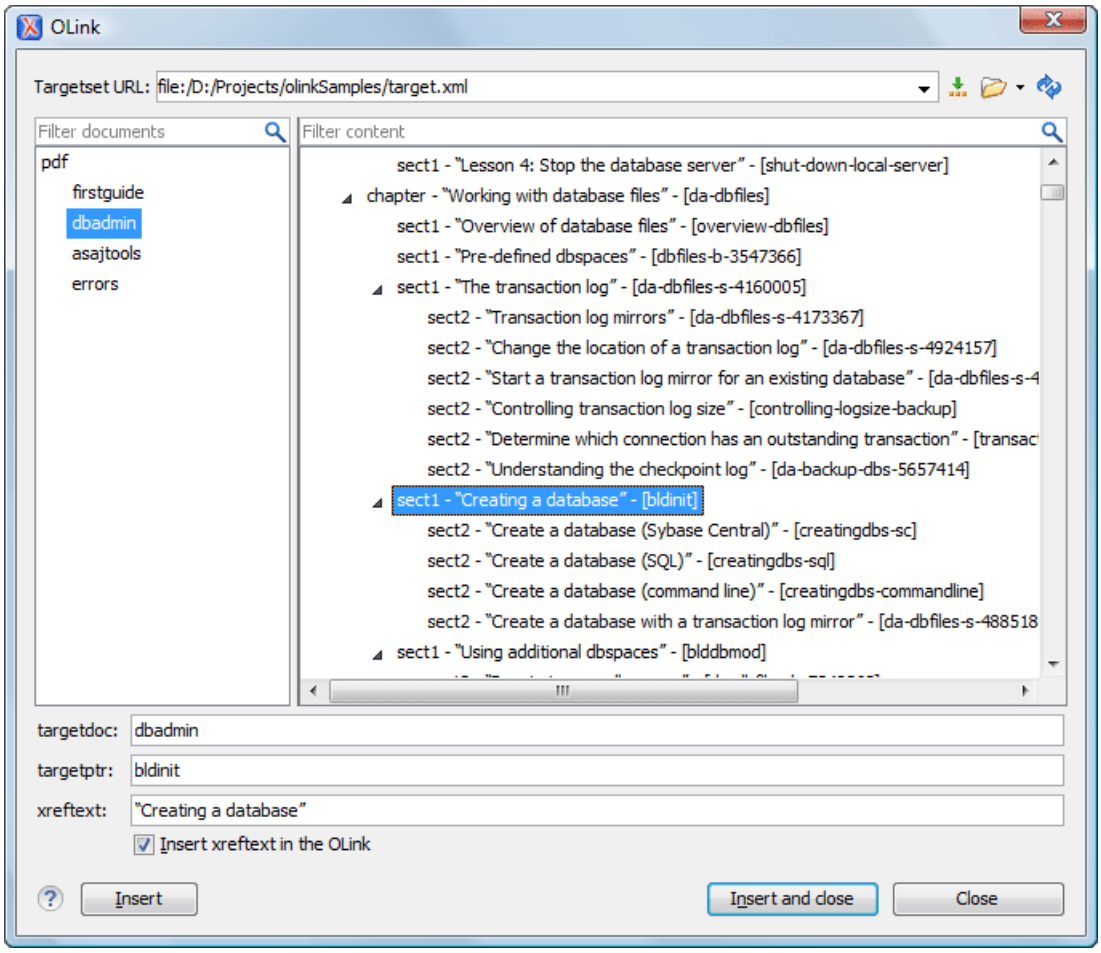

Figure 602: Insert OLink Dialog Box

After you choose the **Targetset URL**, the structure of the target documents is presented. For each target document (`targetdoc`), its content is displayed allowing you to easily identify the `targetptr` for the `olink` element that will be inserted. You can also use the search fields to quickly identify a target. If you already know the values for **targetdoc** and **targetptr**, you can insert them directly in the corresponding fields. You can also edit an `olink` using the **Edit OLink** action that is available on the contextual menu. The last used **Targetset** URL will be used to identify the edited target.

To insert XREF text into the `olink`, enter the text in the **xreftext** field and make sure the **Insert xreftext in the OLink** option is selected.

Insert URI

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

Insert Image

Opens a dialog box that allows you to select the path of an *image to insert at the cursor position*. Depending on the current location, an image-type element is inserted. If the action is invoked between two block elements (such as paragraphs), the dialog box also allows you to provide a title.

Insert Media Resource

Opens a ***Choose Media*** *dialog box* that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in **Author** mode so that it can be played directly from there.

Insert XInclude

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

Section Drop-Down Menu

The following actions are available from this menu:

Insert Section

Inserts a new section or subsection in the document, depending on the current context. For example, if the current context is `sect1`, then a `sect2` is inserted. By default, this action also inserts a `para` element as a child node. The `para` element can be deleted if it is not needed.

Promote Section (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))

Promotes the current node as a sibling of the parent node.

Demote Section (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))

Demotes the current node a child of the previous node.

Insert Paragraph

Insert a new paragraph element at current cursor position.

Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

Insert List Item

Inserts a list item in the current list type.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert Itemized List

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

Insert Variable List

Inserts a DocBook variable list. A child list item is also inserted automatically by default. You can also use this action to convert selected paragraphs or other types of lists to a variable list.

Insert Procedure List

Inserts a DocBook `procedure` element. A step `child` item is also inserted automatically. You can also use this action to convert selected paragraphs or other types of lists to a procedure list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content — text + markup — that is rendered inside a *block element*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Column After

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

DocBook4 Menu Actions

In addition, the following default actions are available in the **DocBook4** menu when editing in **Author** mode:

Paste special submenu

This submenu includes the following special paste actions that are specific to the DocBook 4 *framework*:

Paste As XInclude

Allows you to create an `xi:include` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as link

Allows you to create a `link` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as xref

Allows you to create an `xref` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Insert Column Before

Inserts a column before the current one.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content

This option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. If this option is not selected, IDs are always retained when you copy or cut content and paste it in the same document or other documents. If this option is selected, IDs are never retained for copied content, but if you cut the content, they are preserved for the first paste action (and not retained for any subsequent paste actions).

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

DocBook 4 Contextual Menu Actions

In addition to many of the *DocBook 4 toolbar actions* and the *general **Author** mode contextual menu actions*, the following DocBook 4 *framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Paste special submenu

This submenu includes the following special paste actions that are specific to the DocBook 4 *framework*:

Paste As XInclude

Allows you to create an `xi:include` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as link

Allows you to create a `link` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as xref

Allows you to create an `xref` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

Link > Edit OLink

Opens a dialog box that allows you edit an existing OLink. See the **Insert OLink** action for more information.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

DocBook 4 Drag/Drop (or Copy/Paste) Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a DocBook 4 document that is edited in **Author** mode, creates a link to the dragged file (the `ulink` DocBook element) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the ***Project*** *view* and drop them into a DocBook 4 document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the `inlinegraphic` DocBook element with a `fileref` attribute).

DocBook 4 Transformation Scenarios

Default transformation scenarios allow you to convert DocBook 4 to DocBook 5 documents and transform DocBook documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. All of them are listed in the **DocBook 4** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

Related Information:

Editing a Transformation Scenario on page 1136
Configure Transformation Scenario(s) Dialog Box on page 1138
Apply Associated Transformation Scenarios on page 1141

DocBook 4 to WebHelp Output

DocBook 4 documents can be transformed into several types of WebHelp systems.

WebHelp Classic Output

To publish a DocBook 4 document as a **WebHelp Classic** system, follow these steps:

1. Click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
2. Select the **DocBook WebHelp Classic** scenario from the **DocBook 4** section.
3. Click **Apply associated**.

   When the **DocBook WebHelp Classic** transformation is complete, the output is automatically opened in your default browser.

WebHelp Classic with Feedback Output

To publish a DocBook 4 document as a **WebHelp Classic with Feedback** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic with Feedback** scenario from the **DocBook 4** section.
3. Click **Apply associated**.
4. Enter the documentation product ID and the documentation version.

   When the **DocBook WebHelp Classic with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment. For more information, see *Deploying a Feedback-Enabled WebHelp System* on page 1160.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

WebHelp Classic Mobile Output

To publish a DocBook 4 document as a **WebHelp Classic Mobile** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic Mobile** scenario from the **DocBook 4** section.
3. Click **Apply associated**.

When the **DocBook WebHelp Classic Mobile** transformation is complete, the output is automatically opened in your default browser.

Customizing WebHelp Transformation Scenarios

To customize a DocBook WebHelp transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

l10n.gentext.default.language

This parameter is used to identify the correct stemmer that differs from language to language. For example, for English the value of this parameter is `en` or for French it is `fr`, and so on.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, `mobile-phone-user-guide`, `hvac-installation-guide`).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.skin.css

Path to a CSS file that sets the style theme in the output WebHelp pages. It can be one of the predefined skin CSS from the `OXYGEN_INSTALL_DIR\frameworks\docbook\xsl\com.oxygenxml.webhelp\predefined-skins` directory, or it can be a custom skin CSS generated with the *Oxygen Skin Builder* web application.

For more information about all the DocBook transformation parameters, go to *http://docbook.sourceforge.net/release/xsl/current/doc/fo/index.html*.

Customizing WebHelp Classic Mobile Systems on page 1239

DocBook to PDF Output Customization

When the default layout and output of the DocBook to PDF transformation needs to be customized, follow these steps:

1. Create a custom version of the DocBook title spec file.

   You should start from a copy of the file *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/fo/titlepage.templates.xml` and customize it. The instructions for the spec file can be found *here.*

   An example of spec file:

   ```
   <t:titlepage-content t:side="recto">
       <mediaobject/>
       <title
           t:named-template="book.verso.title"
           font-size="&hsize2;"
           font-weight="bold"
           font-family="{$title.font.family}"/>
       <corpauthor/>
         ...
   </t:titlepage-content>
   ```

2. Generate a new XSLT stylesheet from the title spec file from the previous step.

   Apply *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/template/titlepage.xsl` to the title spec file. The result is an XSLT stylesheet (for example, `mytitlepages.xsl`).

3. Import `mytitlepages.xsl` in a *DocBook customization layer*.

   The customization layer is the stylesheet that will be applied to the XML document. The `mytitlepages.xsl` should be imported with an element like this:

   ```
   <xsl:import href="dir-name/mytitlepages.xsl"/>
   ```

4. Insert a logo image in the XML document.

   The path to the logo image must be inserted in the `book/info/mediaobject` element of the XML document.

5. Apply the customization layer to the XML document.

   A quick way is to duplicate the transformation scenario **DocBook PDF** that is included with Oxygen XML Editor and set the customization layer in *the **XSL URL** property of the scenario*.

Related Information:

*The book **DocBook XSL: The Complete Guide** by Bob Stayton contains more details about customizing the PDF output.*
Video demonstration for creating a DocBook customization layer in Oxygen XML Editor.

DocBook to EPUB Transformation

The EPUB specification recommends the use of *OpenType* fonts (recognized by their `.otf` file extension) when possible. To use a specific font, follow these steps:

1. Declare it in your CSS file, as in the following example:

```
@font-face {
font-family: "MyFont";
font-weight: bold;
font-style: normal;
src: url(fonts/MyFont.otf);
}
```

2. In the CSS, specify where this font is used. To set it as default for `h1` elements, use the `font-family` rule, as in the following example:

```
h1 {
font-size:20pt;
margin-bottom:20px;
font-weight: bold;
font-family: "MyFont";
text-align: center;
}
```

3. Open the ***Configure Transformation Scenario(s)*** *dialog box*, select the **DocBook EPUB** transformation scenario, and click **Edit**.
4. In the **Parameters** tab, set the `epub.embedded.fonts` parameter to `fonts/MyFont.otf`. If you need to provide more files, use commas to separate their file paths.

   Note: The `html.stylesheet` parameter allows you to include a custom CSS in the output EPUB.
5. Run the transformation scenario.

DocBook to DITA Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to DITA. This transformation scenario is based upon a DITA Open Toolkit plugin that is available at *sourceforge.net*.

To convert a DocBook document to DITA, follow these steps:

1. Use one of the following two methods to begin the transformation process:
   - To apply the transformation scenario to a newly opened file, use the  **Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
   - To customize the transformation or change the scenario that is associated with the document, use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
2. Select the **DocBook to DITA** transformation scenario in the **DocBook 4** or **DocBook 5** section.
3. Click the **Apply associated** button to run the transformation.

   Step Result: The transformation will convert as many of the DocBook elements into equivalent DITA elements as it can recognize in its mapping process. For elements that cannot be mapped, the transformation will insert XML comments so that you can see which elements could not be converted.
4. Adjust the resulting DITA composite to suit your needs. You may have to remove comments, fix validation errors, adjust certain attributes, or split the content into individual topics.

Inserting an `olink` in DocBook Documents

The `olink` element is used for linking to resources outside the current DocBook document. The `targetdoc` attribute is used for the document ID that contains the target element and the `targetptr` attribute for the ID of the target element (the value of an `id` or `xml:id` attribute). The combination of those two attributes provides a unique identifier to locate cross references.

For example, a *Mail Administrator Guide* with the document ID `MailAdminGuide` might contain a chapter about user accounts, like this:

```
<chapter id="user_accounts">
<title>Administering User Accounts</title>
```

```
<para>blah blah</para>
```

You can form a cross reference to that chapter by adding an `olink`, as in the following example:

```
You may need to update your
<olink targetdoc="MailAdminGuide" targetptr="user_accounts">user accounts
</olink>
when you get a new machine.
```

To use an `olink` to create links between documents, follow these steps:

1. Decide which documents are to be included in the domain for cross referencing.

   A unique ID must be assigned to each document that will be referenced with an `olink`. It is usually added as an `id` (or `xml:id` for DocBook5) attribute to the root element of the document.
2. Decide on your output hierarchy.

   For creating links between documents, the relative locations of the output documents must be known. Before going further you must decide the names and locations of the output directories for all the documents from the domain. Each directory will be represented by an element: `<dir name="directory_name">`, in the target database document.
3. Create the target database document.

   Each collection of documents has a master target database document that is used to resolve all `olinks` from that collection. The target database document is an XML file that is created once. It provides a means for pulling in the target data for each document. The database document is static and all the document data is pulled in dynamically.

   Example: The following is an example of a target database document. It structures a collection of documents in a `sitemap` element that provides the relative locations of the outputs (HTML in this example). Then it pulls in the individual target data using system entity references to target data files that will be created in the next step.

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <!DOCTYPE targetset [
   <!ENTITY ugtargets SYSTEM "file:///doc/userguide/target.db">
   <!ENTITY agtargets SYSTEM "file:///doc/adminguide/target.db">
   <!ENTITY reftargets SYSTEM "file:///doc/man/target.db">
   ]>
   <targetset>
     <targetsetinfo>
       Description of this target database document,
       which is for the examples in olink doc.
     </targetsetinfo>

     <!-- Site map for generating relative paths between documents -->
     <sitemap>
       <dir name="documentation">
         <dir name="guides">
           <dir name="mailuser">
             <document targetdoc="MailUserGuide"
                       baseuri="userguide.html">
               &ugtargets;
             </document>
           </dir>
           <dir name="mailadmin">
             <document targetdoc="MailAdminGuide">
               &agtargets;
             </document>
           </dir>
         </dir>
         <dir name="reference">
           <dir name="mailref">
             <document targetdoc="MailReference">
               &reftargets;
             </document>
           </dir>
         </dir>
       </dir>
     </sitemap>
   </targetset>
   ```
4. Generate the target data files by executing a DocBook transformation scenario.

   Before applying the transformation, you need to edit the transformation scenario, go to the **Parameters** tab, and make sure the value of the `collect.xref.targets` parameter is set to `yes`. The default name of a target data file is `target.db`, but it can be changed by setting an absolute file path in the `targets.filename` parameter.

Example: An example of a `target.db` file:

```
<div element="book" href="#MailAdminGuide" number="1" targetptr="user_accounts">
 <ttl>Administering User Accounts</ttl>
 <xreftext>How to administer user accounts</xreftext>
 <div element="part" href="#d5e4" number="I">
  <ttl>First Part</ttl>
  <xreftext>Part I, “First Part”</xreftext>
  <div element="chapter" href="#d5e6" number="1">
    <ttl>Chapter Title</ttl>
    <xreftext>Chapter 1, Chapter Title</xreftext>
    <div element="sect1" href="#src_chapter" number="1" targetptr="src_chapter">
      <ttl>Section1 Title</ttl>
      <xreftext>xreflabel_here</xreftext>
    </div>
  </div>
 </div>
</div>
```

5. Insert `olink` elements in the DocBook documents.

   When editing a DocBook XML document in **Author** mode, the **Insert OLink** action is available in the **Link** drop-down menu from the toolbar. This action opens the **Insert OLink** dialog box that allows you to select the target of an `olink` from the list of all possible targets from a specified target database document (specified in the **Targetset URL** field). Once a **Targetset URL** is selected, the structure of the target documents is presented. For each target document (`targetdoc`), its content is displayed, allowing you to easily identify the appropriate `targetptr`. You can also use the search fields to quickly identify a target. If you already know the values for the `targetdoc` and `targetptr` attributes, you can insert them directly in the corresponding fields.

   Example: In the following image, the target database document is called `target.xml`, *dbadmin* is selected for the target document (`targetdoc`), and *bldinit* is selected as the value for the `targetptr` attribute. Notice that you can also add XREF text into the `olink` by using the `xreftext` field.

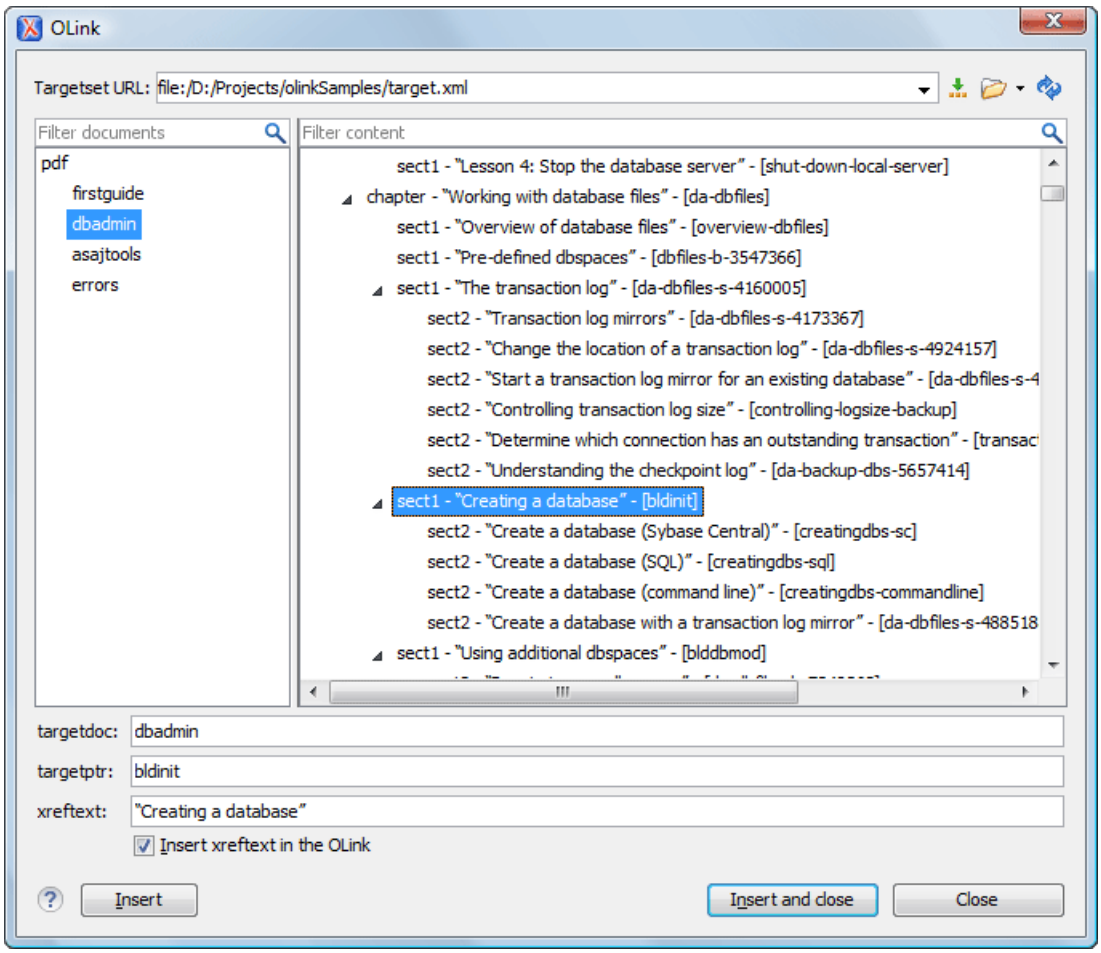

Figure 603: Insert OLink Dialog Box

6. Process a DocBook transformation for each document to generate the output.
   a) Edit the transformation scenario and set the value of the `target.database.document` parameter to be the URL of the target database document.
   b) Apply the transformation scenario.

DocBook 5 Document Type (Framework)

DocBook is a very popular set of tags for describing books, articles, and other prose documents, particularly technical documentation. DocBook provides a vast number of semantic element tags, divided into three broad categories: structural, *block-level*, and *inline*. DocBook content can then be published in a variety of formats, including HTML, PDF, WebHelp, and EPUB.

File Definition

A file is considered to be a DocBook 5 document when the namespace is *http://docbook.org/ns/docbook*.

Default Document Templates

There are a variety of default *DocBook 5* templates available when creating *new documents from templates* and they can be found in: **Framework Templates** > **DocBook 5** > **DocBook 5.0** and **Framework Templates** > **DocBook 5** > **DocBook 5.1**.

New file templates for both DocBook 5 documents are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/templates/Docbook5.0` folder.

New file templates for both DocBook 5.1 documents are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/templates/Docbook5.1` folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is `docbookxi.rng` and it is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/5.0/rng/` (or for DocBook 5.1 in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/5.1/rng/`). Other types of schemas for various DocBook versions are also located in various folders inside the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/` directory.

Default CSS

The default CSS files used for rendering DocBook content in **Author** mode is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Transformation Scenarios

Oxygen XML Editor includes numerous built-in DocBook transformation scenarios that allow you to transform DocBook 5 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, EPUB, and Assembly (5.1). For more information, see the *DocBook 5 Transformation Scenarios* on page 994 section.

DocBook 5 Author Mode Actions

A variety of actions are available in the DocBook 5 *framework* that can be added to the **DocBook5** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

DocBook 5 Toolbar Actions

The following default actions are readily available on the **DocBook (Author Custom Actions)** toolbar when editing in **Author** mode (by default, most of them are also available in the **DocBook5** menu and in various submenus of the contextual menu):

Bold

Emphasizes the selected text by surrounding it with `<emphasis role="bold">` tag. You can use this action on multiple non-contiguous selections.

Italic

Emphasizes the selected text by surrounding it with `<emphasis role="italic">` tag. You can use this action on multiple non-contiguous selections.

Underline

Emphasizes the selected text by surrounding it with `<emphasis role="underline">` tag. You can use this action on multiple non-contiguous selections.

Link Actions Drop-Down Menu

The following link actions are available from this menu:

Cross reference (link)

Opens a dialog box that allows you to select a target to insert as a hypertext link.

Cross reference (xref)

Inserts a cross reference to other parts of the document.

Web Link (ulink)

Inserts a link that addresses its target with a URL (Universal Resource Locator).

Insert OLink

Opens an **OLink** dialog box that allows you to insert a link that addresses its target indirectly, using the `targetdoc` and `targetptr` values that are present in a ***Targetset*** file.

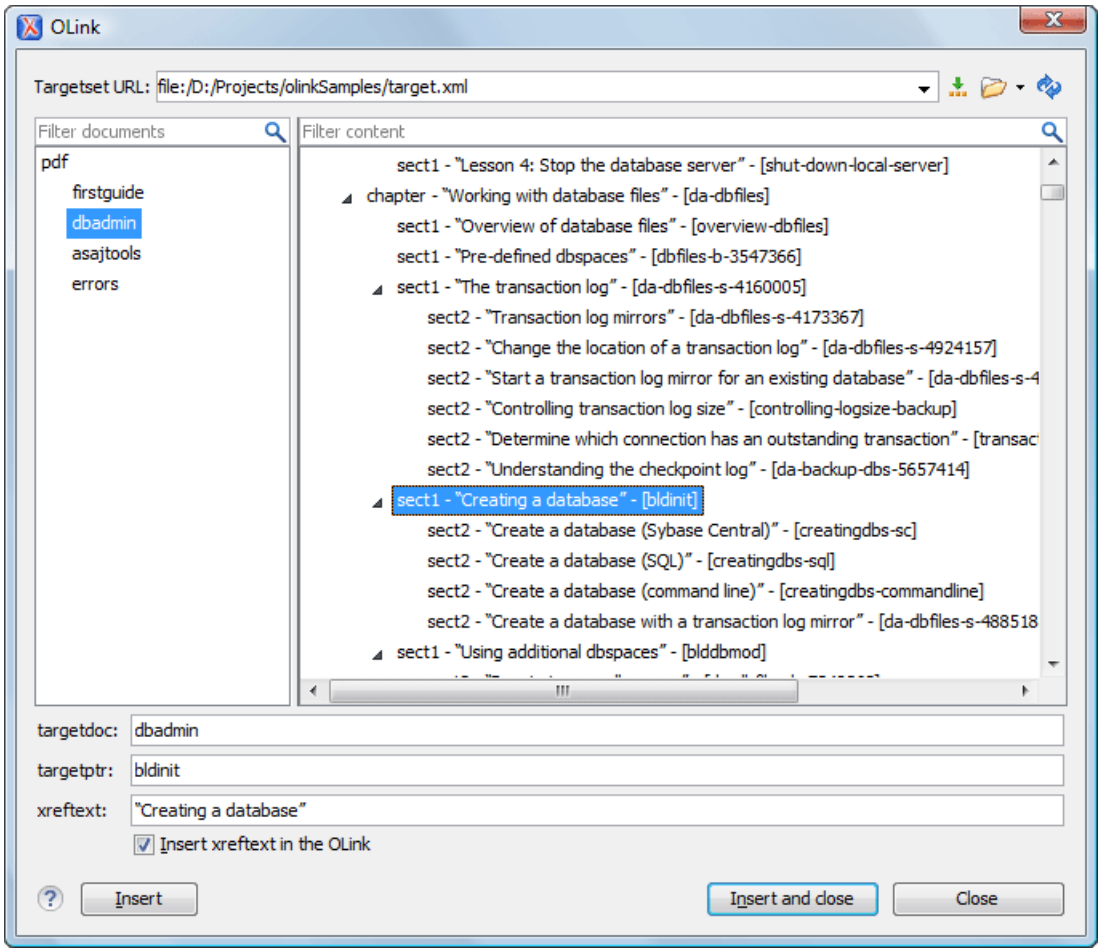

Figure 604: Insert OLink Dialog Box

After you choose the **Targetset URL**, the structure of the target documents is presented. For each target document (`targetdoc`), its content is displayed allowing you to easily identify the `targetptr` for the `olink` element that will be inserted. You can also use the search fields to quickly identify a target. If you already know the values for **targetdoc** and **targetptr**, you can insert them directly in the corresponding fields. You can also edit an `olink` using the **Edit OLink** action that is available on the contextual menu. The last used **Targetset** URL will be used to identify the edited target.

To insert XREF text into the `olink`, enter the text in the **xreftext** field and make sure the **Insert xreftext in the OLink** option is selected.

Insert URI

Inserts a URI element. The URI identifies a Uniform Resource Identifier (URI) in content.

Insert Image

Opens a dialog box that allows you to select the path of an *image to insert at the cursor position*. Depending on the current location, an image-type element is inserted. If the action is invoked between two block elements (such as paragraphs), the dialog box also allows you to provide a title.

Insert Media Resource

Opens a ***Choose Media*** *dialog box* that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in **Author** mode so that it can be played directly from there.

Insert XInclude

Opens a dialog box that allows you to browse and select content to be included and automatically generates the corresponding XInclude instruction.

Section Drop-Down Menu

The following actions are available from this menu:

Insert Section

Inserts a new section or subsection in the document, depending on the current context. For example, if the current context is `sect1`, then a `sect2` is inserted. By default, this action also inserts a `para` element as a child node. The `para` element can be deleted if it is not needed.

Promote Section (Ctrl + Alt + LeftArrow (Command + Alt + LeftArrow on OS X))

Promotes the current node as a sibling of the parent node.

Demote Section (Ctrl + Alt + RightArrow (Command + Alt + RightArrow on OS X))

Demotes the current node a child of the previous node.

Insert Paragraph

Insert a new paragraph element at current cursor position.

Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

Insert List Item

Inserts a list item in the current list type.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert Itemized List

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

Insert Variable List

Inserts a DocBook variable list. A child list item is also inserted automatically by default. You can also use this action to convert selected paragraphs or other types of lists to a variable list.

Insert Procedure List

Inserts a DocBook `procedure` element. A step `child` item is also inserted automatically. You can also use this action to convert selected paragraphs or other types of lists to a procedure list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content — text + markup — that is rendered inside a *block element*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Column After

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

DocBook5 Menu Actions

In addition, the following default actions are available in the **DocBook5** menu when editing in **Author** mode:

Paste special submenu

This submenu includes the following special paste actions that are specific to the DocBook 5 *framework*:

Paste As XInclude

Allows you to create an `xi:include` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as link

Allows you to create a `link` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as xref

Allows you to create an `xref` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Insert Column Before

Inserts a column before the current one.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content

This option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. If this option is not selected, IDs are always retained when you copy or cut content and paste it in the same document or other documents. If this option is selected, IDs are never retained for copied content, but if you cut the content, they are preserved for the first paste action (and not retained for any subsequent paste actions).

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

DocBook 5 Contextual Menu Actions

In addition to many of the *DocBook 5 toolbar actions* and the *general **Author** mode contextual menu actions*, the following DocBook 5 *framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Paste special submenu

This submenu includes the following special paste actions that are specific to the DocBook 5 *framework*:

Paste As XInclude

Allows you to create an `xi:include` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as link

Allows you to create a `link` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Paste as xref

Allows you to create an `xref` element that references a DocBook element copied from **Author** mode. The operation fails if the copied element does not have a declared ID.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

Link > Edit OLink

Opens a dialog box that allows you edit an existing OLink. See the **Insert OLink** action for more information.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

DocBook 5 Drag/Drop (or Copy/Paste) Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a DocBook 5 document that is edited in **Author** mode, creates a link to the dragged file (the `link` DocBook element) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the ***Project*** *view* and drop them into a DocBook 5 document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the `imageobject` DocBook element with an `imagedata` child element and a `fileref` attribute).

DocBook 5 Transformation Scenarios

Built-in transformation scenarios allow you to transform DocBook 5 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. Oxygen XML Editor also includes a DocBook 5.1 transformation scenario for *Assembly* documents. All of them are listed in the **DocBook 5** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

Apply Associated Transformation Scenarios on page 1141

DocBook 5 to WebHelp Output

DocBook 5 documents can be transformed into several types of WebHelp systems.

WebHelp Classic Output

To publish a DocBook 5 document as a **WebHelp Classic** system, follow these steps:

1. Click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
2. Select the **DocBook WebHelp Classic** scenario from the **DocBook 5** section.
3. Click **Apply associated**.

   When the **DocBook WebHelp Classic** transformation is complete, the output is automatically opened in your default browser.

WebHelp Classic with Feedback Output

To publish a DocBook 5 document as a **WebHelp Classic with Feedback** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic with Feedback** scenario from the **DocBook 5** section.
3. Click **Apply associated**.
4. Enter the documentation product ID and the documentation version.

   When the **DocBook WebHelp Classic with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment. For more information, see *Deploying a Feedback-Enabled WebHelp System*.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

WebHelp Classic Mobile Output

To publish a DocBook 5 document as a **WebHelp Classic Mobile** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic Mobile** scenario from the **DocBook 5** section.
3. Click **Apply associated**.

When the **DocBook WebHelp Classic Mobile** transformation is complete, the output is automatically opened in your default browser.

Customizing WebHelp Transformation Scenarios

To customize a DocBook WebHelp transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

l10n.gentext.default.language

This parameter is used to identify the correct stemmer that differs from language to language. For example, for English the value of this parameter is `en` or for French it is `fr`, and so on.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, `mobile-phone-user-guide`, `hvac-installation-guide`).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.skin.css

Path to a CSS file that sets the style theme in the output WebHelp pages. It can be one of the predefined skin CSS from the `OXYGEN_INSTALL_DIR\frameworks\docbook\xsl\com.oxygenxml.webhelp\predefined-skins` directory, or it can be a custom skin CSS generated with the *Oxygen Skin Builder* web application.

For more information about all the DocBook transformation parameters, go to *http://docbook.sourceforge.net/release/xsl/current/doc/fo/index.html*.

Customizing WebHelp Classic Mobile Systems on page 1239

DocBook to PDF Output Customization

When the default layout and output of the DocBook to PDF transformation needs to be customized, follow these steps:

1. Create a custom version of the DocBook title spec file.

   You should start from a copy of the file *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/fo/titlepage.templates.xml` and customize it. The instructions for the spec file can be found *here.*

   An example of spec file:

   ```
   <t:titlepage-content t:side="recto">
       <mediaobject/>
       <title
           t:named-template="book.verso.title"
           font-size="&hsize2;"
           font-weight="bold"
           font-family="{$title.font.family}"/>
       <corpauthor/>
         ...
   </t:titlepage-content>
   ```

2. Generate a new XSLT stylesheet from the title spec file from the previous step.

   Apply *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/template/titlepage.xsl` to the title spec file. The result is an XSLT stylesheet (for example, `mytitlepages.xsl`).

3. Import `mytitlepages.xsl` in a *DocBook customization layer*.

   The customization layer is the stylesheet that will be applied to the XML document. The `mytitlepages.xsl` should be imported with an element like this:

   ```
   <xsl:import href="dir-name/mytitlepages.xsl"/>
   ```

4. Insert a logo image in the XML document.

   The path to the logo image must be inserted in the `book/info/mediaobject` element of the XML document.

5. Apply the customization layer to the XML document.

   A quick way is to duplicate the transformation scenario **DocBook PDF** that is included with Oxygen XML Editor and set the customization layer in *the **XSL URL** property of the scenario*.

Related Information:

*The book **DocBook XSL: The Complete Guide** by Bob Stayton contains more details about customizing the PDF output.*
Video demonstration for creating a DocBook customization layer in Oxygen XML Editor.

Show Comments and Tracked Changes in DocBook 5 PDF Output

To include comments and *tracked changes* (stored within your DocBook 5 documents) in the PDF output, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button.
2. Select **DocBook PDF (Show Change Tracking and Comments)** in the **DocBook 5** section.
3. If you need to configure the transformation, click the ***Edit*** or ***Duplicate*** button, make your changes to the scenario, and click **OK**.
4. Click the **Apply Associated** button to run the transformation scenario.

   Result: Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

DocBook to EPUB Transformation

The EPUB specification recommends the use of *OpenType* fonts (recognized by their `.otf` file extension) when possible. To use a specific font, follow these steps:

1. Declare it in your CSS file, as in the following example:

```
@font-face {
font-family: "MyFont";
font-weight: bold;
font-style: normal;
src: url(fonts/MyFont.otf);
}
```

2. In the CSS, specify where this font is used. To set it as default for `h1` elements, use the `font-family` rule, as in the following example:

```
h1 {
font-size:20pt;
margin-bottom:20px;
font-weight: bold;
font-family: "MyFont";
text-align: center;
}
```

3. Open the ***Configure Transformation Scenario(s)*** *dialog box*, select the **DocBook EPUB** transformation scenario, and click **Edit**.
4. In the **Parameters** tab, set the `epub.embedded.fonts` parameter to `fonts/MyFont.otf`. If you need to provide more files, use commas to separate their file paths.

   Note: The `html.stylesheet` parameter allows you to include a custom CSS in the output EPUB.
5. Run the transformation scenario.

DocBook to DITA Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to DITA. This transformation scenario is based upon a DITA Open Toolkit plugin that is available at *sourceforge.net*.

To convert a DocBook document to DITA, follow these steps:

1. Use one of the following two methods to begin the transformation process:
   - To apply the transformation scenario to a newly opened file, use the **Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
   - To customize the transformation or change the scenario that is associated with the document, use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
2. Select the **DocBook to DITA** transformation scenario in the **DocBook 4** or **DocBook 5** section.
3. Click the **Apply associated** button to run the transformation.

   Step Result: The transformation will convert as many of the DocBook elements into equivalent DITA elements as it can recognize in its mapping process. For elements that cannot be mapped, the transformation will insert XML comments so that you can see which elements could not be converted.
4. Adjust the resulting DITA composite to suit your needs. You may have to remove comments, fix validation errors, adjust certain attributes, or split the content into individual topics.

Configure Transformation Scenario(s) Dialog Box on page 1138

Inserting an `olink` in DocBook Documents

The `olink` element is used for linking to resources outside the current DocBook document. The `targetdoc` attribute is used for the document ID that contains the target element and the `targetptr` attribute for the ID of the target element (the value of an `id` or `xml:id` attribute). The combination of those two attributes provides a unique identifier to locate cross references.

For example, a *Mail Administrator Guide* with the document ID `MailAdminGuide` might contain a chapter about user accounts, like this:

```
<chapter id="user_accounts">
<title>Administering User Accounts</title>
<para>blah blah</para>
```

You can form a cross reference to that chapter by adding an `olink`, as in the following example:

```
You may need to update your
<olink targetdoc="MailAdminGuide" targetptr="user_accounts">user accounts
</olink>
when you get a new machine.
```

To use an `olink` to create links between documents, follow these steps:

1. Decide which documents are to be included in the domain for cross referencing.

   A unique ID must be assigned to each document that will be referenced with an `olink`. It is usually added as an `id` (or `xml:id` for DocBook5) attribute to the root element of the document.
2. Decide on your output hierarchy.

   For creating links between documents, the relative locations of the output documents must be known. Before going further you must decide the names and locations of the output directories for all the documents from the domain. Each directory will be represented by an element: `<dir name="directory_name">`, in the target database document.
3. Create the target database document.

   Each collection of documents has a master target database document that is used to resolve all `olinks` from that collection. The target database document is an XML file that is created once. It provides a means for pulling in the target data for each document. The database document is static and all the document data is pulled in dynamically.

   Example: The following is an example of a target database document. It structures a collection of documents in a `sitemap` element that provides the relative locations of the outputs (HTML in this example). Then it pulls in the individual target data using system entity references to target data files that will be created in the next step.

   ```
   <?xml version="1.0" encoding="utf-8"?>
   <!DOCTYPE targetset [
   <!ENTITY ugtargets SYSTEM "file:///doc/userguide/target.db">
   <!ENTITY agtargets SYSTEM "file:///doc/adminguide/target.db">
   <!ENTITY reftargets SYSTEM "file:///doc/man/target.db">
   ]>
   <targetset>
     <targetsetinfo>
       Description of this target database document,
       which is for the examples in olink doc.
     </targetsetinfo>

     <!-- Site map for generating relative paths between documents -->
     <sitemap>
       <dir name="documentation">
         <dir name="guides">
           <dir name="mailuser">
             <document targetdoc="MailUserGuide"
                       baseuri="userguide.html">
               &ugtargets;
             </document>
           </dir>
           <dir name="mailadmin">
             <document targetdoc="MailAdminGuide">
               &agtargets;
             </document>
           </dir>
         </dir>
         <dir name="reference">
           <dir name="mailref">
   ```

```
          <document targetdoc="MailReference">
            &reftargets;
          </document>
        </dir>
      </dir>
    </dir>
  </sitemap>
</targetset>
```

4. Generate the target data files by executing a DocBook transformation scenario.

   Before applying the transformation, you need to edit the transformation scenario, go to the **Parameters** tab, and make sure the value of the `collect.xref.targets` parameter is set to `yes`. The default name of a target data file is `target.db`, but it can be changed by setting an absolute file path in the `targets.filename` parameter.

   Example: An example of a `target.db` file:

```
<div element="book" href="#MailAdminGuide" number="1" targetptr="user_accounts">
 <ttl>Administering User Accounts</ttl>
 <xreftext>How to administer user accounts</xreftext>
 <div element="part" href="#d5e4" number="I">
  <ttl>First Part</ttl>
  <xreftext>Part I, “First Part”</xreftext>
  <div element="chapter" href="#d5e6" number="1">
    <ttl>Chapter Title</ttl>
    <xreftext>Chapter 1, Chapter Title</xreftext>
    <div element="sect1" href="#src_chapter" number="1" targetptr="src_chapter">
      <ttl>Section1 Title</ttl>
      <xreftext>xreflabel_here</xreftext>
    </div>
  </div>
 </div>
</div>
```

5. Insert `olink` elements in the DocBook documents.

   When editing a DocBook XML document in **Author** mode, the **Insert OLink** action is available in the **Link** drop-down menu from the toolbar. This action opens the **Insert OLink** dialog box that allows you to select the target of an `olink` from the list of all possible targets from a specified target database document (specified in the **Targetset URL** field). Once a **Targetset URL** is selected, the structure of the target documents is presented. For each target document (`targetdoc`), its content is displayed, allowing you to easily identify the appropriate `targetptr`. You can also use the search fields to quickly identify a target. If you already know the values for the `targetdoc` and `targetptr` attributes, you can insert them directly in the corresponding fields.

   Example: In the following image, the target database document is called `target.xml`, *dbadmin* is selected for the target document (`targetdoc`), and *bldinit* is selected as the value for the `targetptr` attribute. Notice that you can also add XREF text into the `olink` by using the `xreftext` field.

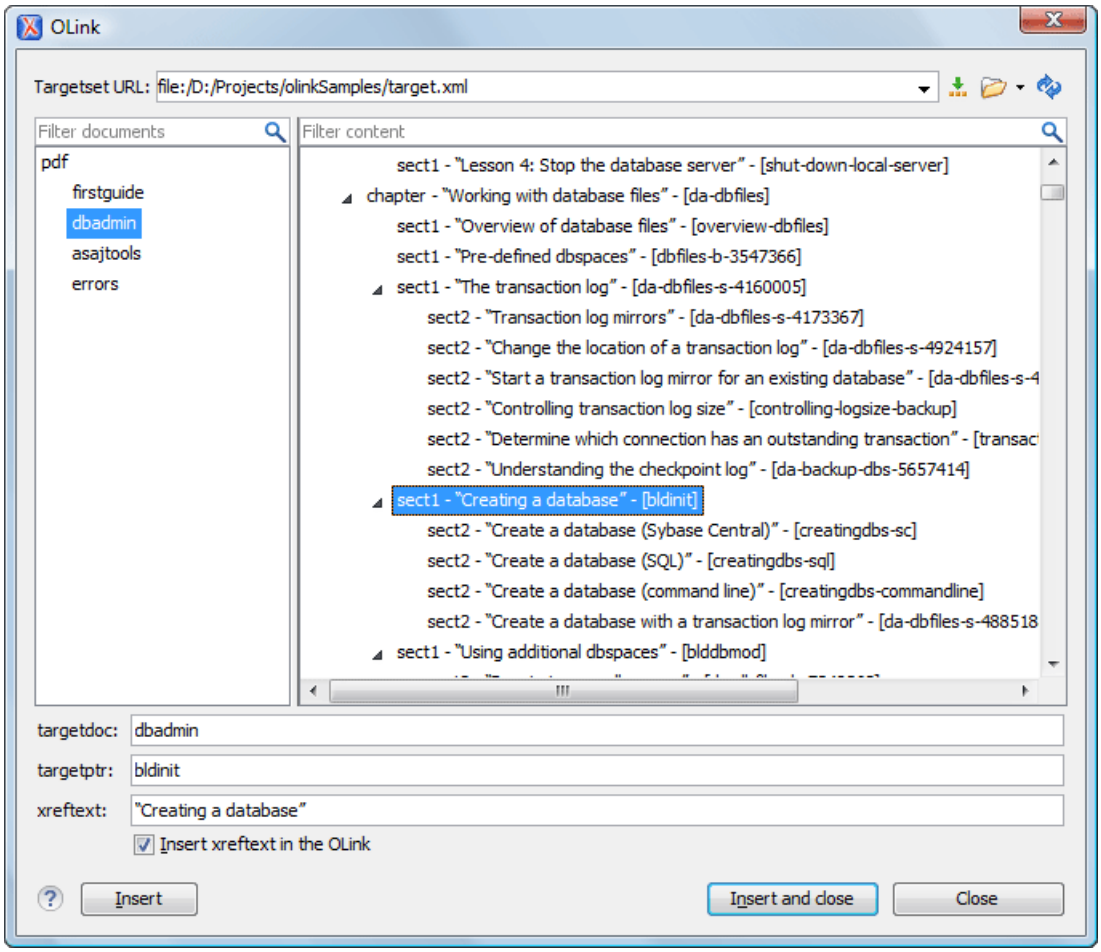

Figure 605: Insert OLink Dialog Box

6. Process a DocBook transformation for each document to generate the output.
   a) Edit the transformation scenario and set the value of the `target.database.document` parameter to be the URL of the target database document.
   b) Apply the transformation scenario.

DocBook 5.1 Assembly

The DocBook *Assembly* document type was introduced with DocBook 5.1 and it is used to define the hierarchy and relationships for a collection of resources. It is especially helpful for topic-oriented authoring scenarios since it assembles a set of resources (such as *DocBook 5.1 topics*) to form a hierarchical structure for a larger publication.

An *Assembly* document usually has four major parts:

- **Resources** - Identifies a collection of resources (such as topics). An *Assembly* may identify one or more collections.
- **Structure** - Identifies an artifact to be assembled. A document in this case is the particular collection of resources (such as topics) that forms the documentation. Within the `structure` element, an `output` element can be used to identify the type of output to be generated and `module` elements can be used to identify the resources to be included. An *Assembly* may identify one or more *structures*.
- **Relationships** - Identifies relationships between resources. These relationships may be manifested in any number of *structures* during assembly. An *Assembly* may identify any number of relationships.
- **Transformations** - Identifies transformations that can be applied during assembly. An *Assembly* may identify any number of transformations.

For detailed information about the DocBook *Assembly* document type, see *DocBook 5.1: The Definitive Guide - DocBook Assemblies*.

File Definition

A file is considered to be an *Assembly* when the root name is `assembly`.

Default Document Templates

A default **Assembly** document template is available when creating *new documents from templates* and it can be found in: **Framework Templates** > **DocBook 5** > **DocBook 5.1**.

The default template for DocBook Assembly documents is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/templates/Docbook5.1` folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is `docbookxi.rng` and it is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/5.1/rng/`.

Transformation Scenarios

Oxygen XML Editor includes a built-in transformation scenario that can be applied on an *Assembly* file to generate an *assembled* (merged) DocBook file. The scenarios is called **DocBook Assembly** and is found in the **DocBook 5** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

Resources

- *DocBook 5.1: The Definitive Guide - DocBook Assemblies*
- *Docbook 5.1 Specifications*
- Sample files: *[OXYGEN_INSTALL_DIR]*`/samples/docbook/v5/assembly/`

DocBook 5.1 Topic

The DocBook *Topic* document type was introduced with DocBook 5.1 and it is used as a modular unit of documentation. It is similar to the concept of the DITA *Topic* and can be used as modular resources in conjunction with *DocBook 5.1 Assembly* documents.

For detailed information about the DocBook *Topic* document type, see *DocBook 5.1: The Definitive Guide - Topic*.

File Definition

A DocBook file is considered to be a *Topic* when the root name is `topic`.

Default Document Templates

A default **Topic** document template is available when creating *new documents from templates* and it can be found in: **Framework Templates** > **DocBook 5** > **DocBook 5.1**.

The default template for DocBook Assembly documents is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/templates/Docbook5.1` folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is `docbookxi.rng` and it is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/5.1/rng/`.

Transformation Scenarios

Since DocBook *Topics* are modular resources, they are *assembled* and transformed in the ***DocBook Assembly*** *transformation process*. You can also use any of the built-in DocBook transformation scenarios to transform individual DocBook Topics to a variety of outputs, such as PDF, HTML, EPUB, and more. They are found in the **DocBook 5** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

DocBook Targetset Document Type (Framework)

DocBook *Targetset* documents are used to resolve cross references with the DocBook `olink`.

File Definition

A file is considered to be a *Targetset* when the root name is `targetset`.

Default Document Templates

A default **Map** document template is available when creating *new documents from templates* and it can be found in: **Framework Templates** > **DocBook Targetset**.

The default template for DocBook Targetset documents is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/templates/Targetset` folder.

Default Schema for Validation and Content Completion

The default schema, `targetdatabase.dtd`, for this type of document is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/common/`.

DITA Topics Document Type (Framework)

The Darwin Information Typing Architecture (DITA) is an XML-based architecture for authoring, producing, and delivering technical information. It divides content into small, self-contained topics that you can reuse in various deliverables. The extensibility of DITA permits organizations to define specific information structures while still using standard tools to work with them. DITA content is created as topics, each an individual XML file. Typically, each topic has a defined primary objective and structure, and DITA also includes several specialized topic types (*task*, *concept*, *reference*, *glossary entry*).

For much more detailed information, resources, and instructions, see the *DITA Authoring and Publishing* on page 1782 chapter.

File Definition

A file is considered to be a DITA topic document when one of the following conditions are true:

- The root element name is one of the following: `concept`, `task`, `reference`, `dita`, or `topic`.
- The PUBLIC ID of the document is a PUBLIC ID for the elements listed above.
- The root element of the file has an attribute named `DITAArchVersion` for the “http://dita.oasis-open.org/architecture/2005/” namespace. This enhanced case of matching is only applied when the ***Enable DTD/XML Schema processing in document type detection*** *option* is selected from the ***Document Type Association*** *preferences page*.

Default Document Templates

There are a variety of default *DITA topic* templates available when creating *new documents from templates* and they can be found in various folders inside: **Framework Templates** > **DITA**.

The default templates for DITA topic documents are located in the *[OXYGEN_INSTALL_DIR]*/frameworks/dita/templates/topic folder.

Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the DITA documents are stored in the various folders inside *DITA-OT-DIR*/dtd/ or *DITA-OT-DIR*/schema/.

Default CSS

The default CSS files used for rendering DITA content in **Author** mode are stored in the various folders inside: *[OXYGEN_INSTALL_DIR]*/frameworks/dita/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalogs

The default *XML Catalogs* for the DITA topic document type are as follows:

- *DITA-OT-DIR*/catalog-dita.xml
- *[OXYGEN_INSTALL_DIR]*/frameworks/dita/catalog.xml
- *[OXYGEN_INSTALL_DIR]*/frameworks/dita/plugin/catalog.xml
- *[OXYGEN_INSTALL_DIR]*/frameworks/dita/styleguide/catalog.xml

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform individual DITA Topics to a XHTML or PDF output. They can be found in the **DITA** section in the ***Configure Transformation Scenario(s)** dialog box*.

DITA Author Mode Actions

A variety of actions are available in the DITA *framework* that can be added to the **DITA** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

DITA Toolbar Actions

The following default actions are readily available on the **DITA (Author Custom Actions)** toolbar when editing in **Author** mode (by default, most of them are also available in the **DITA** menu and in various submenus of the contextual menu):

Bold

Surrounds the selected text with a b tag. You can use this action on multiple non-contiguous selections.

Italic

Surrounds the selected text with an i tag. You can use this action on multiple non-contiguous selections.

Underline

Surrounds the selected text with a u tag. You can use this action on multiple non-contiguous selections.

Link Actions Drop-Down Menu

The following link actions are available from this menu:

Cross Reference

Opens the ***Cross Reference (xref)*** *dialog box* that allows you to insert a link to a target resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. For more information, see *Linking in DITA Topics* on page 1881.

File Reference

Opens the ***File Reference*** *dialog box* that allows you to insert a link to a target file resource at the current location within a document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. For more information, see *Linking in DITA Topics* on page 1881.

Web Link

Opens the ***Web Link*** *dialog box* that allows you to insert a link to a target web-related resource at the current location within a document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. For more information, see *Linking in DITA Topics* on page 1881.

Related Link to Topic

Opens the ***Cross Reference (xref)*** *dialog box* that allows you to insert a link to a target resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. Once the target resource has been selected, you can also target specific elements within that resource. If a related links section does not already exist, this action creates one. For more information, see *Linking in DITA Topics* on page 1881.

Related Link to File

Opens the ***File Reference*** *dialog box* that allows you to insert a link to a target file resource in a related links section at the bottom of the current document. The target resource can be the location of a file or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see *Linking in DITA Topics* on page 1881.

Related Link to Web Page

Opens the ***Web Link*** *dialog box* that allows you to insert a link to a target web-related resource in a related links section at the bottom of the current document. The target resource can be a URL or a key that is already defined in your *DITA map* structure. If a related links section does not already exist, this action creates one. For more information, see *Linking in DITA Topics* on page 1881.

Insert Image

Opens the ***Insert Image*** *dialog box* that allows you to configure the properties of an image to be inserted into a DITA document at the cursor position.

Insert Media Resource

Opens the ***Insert Media*** *dialog box* that allows you to select and configure the properties of a media object to be inserted into a DITA document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted in an `object` element and it is rendered in **Author** mode so that it can be played directly from there.

Insert Section Drop-Down Menu

The following insert actions are available from this menu:

Insert Section

Inserts a new `section` element in the document, depending on the current context.

Insert Concept

Inserts a new `concept` element, depending on the current context. Concepts provide background information that users must know before they can successfully work with a product or interface.

Insert Task

Inserts a new `task` element, depending on the current context. Tasks are the main building blocks for task-oriented user assistance. They generally provide step-by-step instructions that will help a user to perform a task.

Insert Topic

Inserts a new `topic` element, depending on the current context. Topics are the basic units of DITA content and are usually organized around a single subject.

Insert Reference

Inserts a new `reference` element, depending on the current context. A reference is a top-level container for a reference topic.

Insert Paragraph

Inserts a new paragraph at current cursor position.

Reuse Content

This action provides a mechanism for reusing content fragments. It opens the ***Reuse Content*** *dialog box* that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include *content references (conref)*, *content key references (conkeyref)*, or *key references to metadata (keyref)*.

Insert step or list item

Inserts a new list or step item in the current list type.

Insert Unordered List

Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content — text + markup — that is rendered inside a *block element*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Column After

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

DITA Menu Actions

In addition to the *DITA toolbar actions*, the following default actions are available in the **DITA** menu when editing in **Author** mode:

Reuse Content

This action provides a mechanism for reusing content fragments. It opens the ***Reuse Content*** *dialog box* that allows you to insert several types of references to reusable content at the cursor position. The types of references that you can insert using this dialog box include *content references (conref)*, *content key references (conkeyref)*, or *key references to metadata (keyref)*.

Push Current Element

Opens the ***Push current element*** *dialog box* that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

Edit Content Reference

This action is available for elements with a `conref` or `conkeyref` attribute. it opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`conref`/`conkeyref` and `conrefend` attributes). For more information, see *Reuse Content Dialog Box* on page 1864.

Replace Reference with content

Replaces the referenced fragment (`conref` or `conkeyref`) at the cursor position with its content. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location.

Remove Content Reference

Removes the content reference (`conref` or `conkeyref`) inside the element at the cursor position.

Create Reusable Component

Creates a reusable component from the selected fragment of text. For more information, see *Creating a Reusable Content Component* on page 1872.

Insert Reusable Component

Inserts a reusable component at cursor location. For more information, see *Inserting a Reusable Content Component* on page 1873.

Paste special submenu

This submenu includes the following special paste actions that are specific to the DITA *framework*:

Paste as content reference

Inserts a content reference (a DITA element with a `conref` attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The `conref` attribute will point to this ID value.

Paste as content key reference

Allows you to indirectly reference content using the `conkeyref` attribute. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps*. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.

2. In the **DITA Maps Manager** view, make sure that the ***Root map*** *combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Paste as link

Looks for the first element with an ID value in the clipboard and inserts an `xref` that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

Paste as link (keyref)

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the ***Root map*** *combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

 **Insert Row Above**

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

 **Insert Column Before**

Inserts a column before the current one.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

 **Insert Cell**

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Insert > Σ Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is *cut* and *pasted*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Browse DITA Style Guide

Opens the **DITA Style Guide Best Practices for Authors** in your browser and displays a topic that is relevant to the element at the cursor position. When editing DITA documents, this action is available in the contextual menu of the editing area (under the **About Element** sub-menu), in the **DITA** menu, and in some of the documentation tips that are displayed by the *Content Completion Assistant*.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

DITA Contextual Menu Actions

In addition to many of the *DITA toolbar actions* and the *general **Author** mode contextual menu actions*, the following DITA *framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Paste special submenu

This submenu includes the following special paste actions that are specific to the DITA *framework*:

Paste as content reference

Inserts a content reference (a DITA element with a `conref` attribute) to the DITA XML element from the clipboard. An entire DITA XML element with an ID attribute must be present in the clipboard when the action is invoked. The `conref` attribute will point to this ID value.

Paste as content key reference

Allows you to indirectly reference content using the `conkeyref` attribute. When the DITA content is processed, the key references are resolved using key definitions from *DITA maps*. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the ***Root map** combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Paste as link

Looks for the first element with an ID value in the clipboard and inserts an `xref` that points to that element. If no elements with an ID value are found, a message will appear that informs you that to use this action, the clipboard contents must include at least one element with a declared ID.

Paste as link (keyref)

Inserts a link to the element that you want to reference. To use this action, you must first do the following:

1. Make sure the DITA element that contains the copied content has an ID attribute assigned to it.
2. In the **DITA Maps Manager** view, make sure that the ***Root map** combo box* points to the correct map that stores the keys.
3. Make sure the topic that contains the content you want to reference has a key assigned to it. To assign a key, right-click the topic with its parent map opened in the **DITA Maps Manager**, select **Edit Properties**, and enter a value in the **Keys** field.

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

Insert > Σ Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Reuse submenu

This submenu includes the following actions in regards to reusing content in DITA:

Push Current Element

Opens the ***Push current element** dialog box* that allows content from a source topic to be inserted into another topic without any special coding in the topic where the content will be re-used.

Edit Content Reference

This action is available for elements with a `conref` or `conkeyref` attribute. it opens the **Edit Content Reference** dialog box that allows you to edit the source location (or key) and source element of a content reference (or content key reference), and the reference details (`conref`/`conkeyref` and `conrefend` attributes). For more information, see *Reuse Content Dialog Box* on page 1864.

Replace Reference with content

Replaces the referenced fragment (`conref` or `conkeyref`) at the cursor position with its content. This action is useful if you want to make changes to the content in the currently edited document without changing the referenced fragment in its source location.

Remove Content Reference

Removes the content reference (`conref` or `conkeyref`) inside the element at the cursor position.

Create Reusable Component

Creates a reusable component from the selected fragment of text. For more information, see *Creating a Reusable Content Component* on page 1872.

Insert Reusable Component

Inserts a reusable component at cursor location. For more information, see *Inserting a Reusable Content Component* on page 1873.

Search References (Ctrl + Shift + G)

Finds the references to the `id` attribute value for the element at the current cursor position, in all the topics contained in the current *DITA map* (opened in the ***DITA Maps Manager** view*). If no references are found for the current element, a dialog box will be displayed that offers you the option of searching for references to its ancestor elements.

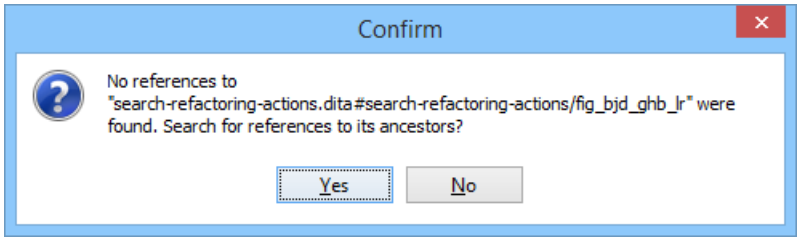

Figure 606: Search References to Ancestors Dialog Box

Show Key Definition

Available for elements that have a `conkeyref` or `keyref` attribute set (or elements with an ancestor element that has a `conkeyref` or `keyref` attribute). It computes the key name and opens the *DITA map* that contains the definition of the key with the element that defines that key selected.

About Element submenu

This submenu includes the following actions:

Style Guide

Opens the **DITA Style Guide Best Practices for Authors** in your browser and displays a topic that is relevant to the element at the cursor position. When editing DITA documents, this action is available in the contextual menu of the editing area (under the **About Element** sub-menu), in the **DITA** menu, and in some of the documentation tips that are displayed by the *Content Completion Assistant*.

Browse reference manual

Opens a reference to the documentation of the XML element closest to the cursor position in a web browser.

Go to Definition

Moves the cursor to the definition of the current element.

DITA Drag/Drop (or Copy/Paste) Actions

Dragging a file from the ***Project** view* or ***DITA Maps Manager** view* and dropping it into a DITA document that is edited in **Author** mode, creates a link to the dragged file (the `xref` DITA element with the `href` attribute) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the ***Project** view* and drop them into a DITA document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the DITA `image` element with an `href` attribute).

DITA Map Document Type (Framework)

DITA maps are documents that collect and organize references to DITA topics to indicate the relationships between the topics. They can be used as a container for topics used to transform a collection of content into a publication and they offer a sequence and structure to the topics. They can also serve as outlines or tables of contents for DITA deliverables and as build manifests for DITA projects. *DITA maps* allow scalable reuse of content across multiple contexts. Maps can reference topics or other maps, and can contain a variety of content types and metadata.

For much more detailed information, resources, and instructions, see the *DITA Authoring and Publishing* on page 1782 chapter.

File Definition

A file is considered to be a *DITA map* document when one of the following conditions are true:

- The root element name is one of the following: `map`, `bookmap`.
- The public ID of the document is `-//OASIS//DTD DITA Map` or `-//OASIS//DTD DITA BookMap`.
- The root element of the file has an attribute named `class` that contains the value `map/map` and a `DITAArchVersion` attribute from the *http://dita.oasis-open.org/architecture/2005/* namespace. This enhanced case of matching is only applied when the ***Enable DTD/XML Schema processing in document type detection*** *option* from the ***Document Type Association*** *preferences page* is selected.

Default Document Templates

There are a variety of default *DITA map* templates available when creating *new documents from templates* and they can be found in various folders inside: **Framework Templates** > **DITA Map**.

The default templates for *DITA map* documents are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/sita/templates/map` folder.

Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the *DITA map* document are stored in the various folders inside *DITA-OT-DIR*`/dtd/` or *DITA-OT-DIR*`/schema/`.

Default CSS

The default CSS files used for rendering DITA content in **Author** mode are stored in the various folders inside: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalogs

The default *XML Catalogs* for the *DITA map* document type are as follows:

- *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/catalog.xml`
- *DITA-OT-DIR*`/catalog-dita.xml`

Transformation Scenarios

Oxygen XML Editor includes numerous built-in transformation scenarios that allow you to transform *DITA maps* to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, and CHM. For more information, see the *DITA Map Transformation Scenarios* on page 1017 section.

DITA Map Author Mode Actions

A variety of actions are available in the *DITA map framework* that can be added to the **DITA** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

DITA Map Toolbar and Menu Actions

When a *DITA map* is opened in **Author** mode, the following default actions are available on the **DITA Map Author Custom Actions** toolbar (by default, they are also available in the **DITA** menu and in various submenus of the contextual menu):

Insert New Topic

Opens a ***New*** *DITA topic dialog box* that allows you to create a new topic and inserts a reference to it at the cursor position.

Insert Topic Reference

Opens the ***Insert Reference*** *dialog box* that allows you to insert and configure a reference to a topic at the cursor position.

Reuse Content

Opens the ***Reuse Content*** *dialog box* that allows you to insert and configure a content reference (`conref`), or a content key reference (`conkeyref`) at the cursor position.

Insert Topic Heading

Opens the ***Insert Reference*** *dialog box* that allows you to insert a topic heading at the cursor position.

Insert Topic Group

Opens the ***Insert Reference*** *dialog box* that allows you to insert a topic group at the cursor position.

Insert Relationship Table

Opens a dialog box that allows you to configure the relationship table to be inserted. The dialog box allows you to configure the number of rows and columns of the relationship table, if the header will be generated and if the title will be added.

Relationship Table Properties

Allows you to change the properties of rows in relationship tables.

Insert Relationship Row

Inserts a new table row with empty cells. The action is available when the cursor position is inside a table.

Insert Relationship Column

Inserts a new table column with empty cells after the current column. The action is available when the cursor position is inside a table.

Delete Relationship Column

Deletes the table column where the cursor is located.

Delete Relationship Row

Deletes the table row where the cursor is located.

Move Up

Moves the selected node up one position on its same level.

Move Down

Moves the selected node down one position on its same level.

Promote(Alt + LeftArrow)

Moves the selected node up one level to the level of its parent node.

Demote(Alt + RightArrow)

Moves the selected node down one level to the level of its child nodes.

DITA Menu Actions

In addition, the following default actions are available in the **DITA** menu when editing a *DITA map* in **Author** mode:

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is *cut* and *pasted*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

DITA Map Contextual Menu Actions

In addition to many of the ***DITA Map*** *toolbar actions* and the *general* ***Author*** *mode contextual menu actions*, the following *DITA map framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Edit Properties

Opens the **Edit Properties** dialog box that allows you to configure the properties of a selected node. For more details about this dialog box, see *Edit Properties Dialog Box* on page 1805.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Search References

Finds the references to the `href` or `keys` attribute value of the topic/map reference element at the current cursor position, in all the topics from the current *DITA map* (opened in the ***DITA Maps Manager*** *view*). The current topic/map reference element must have an `href` or `keys` attribute defined to complete the search.

Show Key Definition

Available for elements that have a `conkeyref` or `keyref` attribute set (or elements with an ancestor element that has a `conkeyref` or `keyref` attribute). It computes the key name and opens the *DITA map* that contains the definition of the key with the element that defines that key selected.

DITA Map Drag/Drop Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a *DITA map* document that is edited in **Author** mode creates a link to the dragged file (a `topicref` element, `chapter`, `part`, etc.) at the drop location.

Open Topic from DITA Map in Author Mode

When a *DITA map* is opened in **Author** mode, you can click the icon to the left of a topic to open that particular topic in the editor.

DITA Map Transformation Scenarios

The following types of transformations scenarios are available for *DITA maps*:

- Predefined transformation scenarios allow you to transform a *DITA map* to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, and MS Word.
- **Run DITA-OT Integrator** - Use this transformation scenario if you want to *integrate a DITA-OT plugin*. This scenario runs an Ant task that integrates all the plugins from the DITA-OT/plugins directory.
- **DITA Map Metrics Report** - Use this type of transformation scenario if you want to generate a *DITA map* statistics report. They contain information such as:
  - The number of processed maps and topics.
  - Content reuse percentage.
  - Number of elements, attributes, words, and characters used in the entire *DITA map* structure.
  - DITA conditional processing attributes used in the *DITA maps*.
  - Words count.
  - Information types such as number of containing *maps*, *bookmaps*, or topics.

DITA Map to WebHelp Output

DITA maps can be transformed into a variety of WebHelp systems designed to suit your specific needs. This section contains the procedures for obtaining the output for the variants of the WebHelp system.

Related Information:

WebHelp System Output on page 1152

WebHelp Responsive Output

To publish a *DITA map* as a **WebHelp Responsive** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Responsive** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

- *Templates Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.
- *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
- *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
- *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
- *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to process the transformation.

   When the **DITA Map WebHelp Responsive** transformation is complete, the output is automatically opened in your default browser.

Parameters for Customizing WebHelp Responsive Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is no).

editlink.remote.ditamap.url

Use this parameter in conjunction with `editlink.web.author.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the *main DITA map*. For example, a GitHub custom URL might look like this: `https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap`.

editlink.web.author.url

This parameter needs to be used in conjunction with `editlink.remote.ditamap.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the URL of the Web Author installation. For example: `https://www.oxygenxml.com/webapp-demo-aws/app/oxygen.html`.

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.enable.pagination

Specifies whether or not search results will be displayed on multiple pages. Allowed values are `yes` or no.

webhelp.search.page.numberOfItems

Specifies the number of search results items displayed on each page. This parameter is only used when the **webhelp.search.enable.pagination** parameter is enabled.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

Parameters Specific to WebHelp Responsive Output

webhelp.default.collection.type

Specifies if the **sequence** value will be used by default when the `collection-type` attribute is not specified. This option is helpful if you want to have *Next* and *Previous* navigational buttons generated for all HTML pages. Allowed values are **no** (default) and **yes**.

webhelp.enable.search.autocomplete

Specifies if the *Autocomplete* feature is enabled in the WebHelp search text field. The default value is `yes`.

webhelp.fragment.after.body

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.logo_and_title

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.main.page.search

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.toc_or_tiles

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.top_menu

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.logo_and_title

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.page.search

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.toc_or_tiles

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.top_menu

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.head

In the generated output it inserts a given XHTML fragment in the `<head>` element. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.welcome

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, *Related Tasks*, *Related References*, *Related Information*) are merged into a single group. The default value is `yes`.

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is `yes`.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is `no`.

webhelp.show.indexterms.link

Specifies if an icon that links to the index will be presented in the output. The default value is `yes`.

webhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a *tree* style layout, this parameter should be set to no.

webhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is `yes`.

webhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is `yes`.

webhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is `yes`.

webhelp.show.related.links

Specifies if the related links component will be presented in the WebHelp Responsive output. The default value is `yes`. The webhelp.merge.nested.topics.related.links parameter can used in conjunction with this one to merge the related links from nested topics into the links in the parent topic.

webhelp.show.side.toc

Specifies if a side table of contents will be presented on the right side of each topic in the output. The default value is `yes`.

webhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is `yes`.

webhelp.side.toc.links

Specifies which links will be included in the side table of contents. The possible values are:

- **chapter** (default) - The side TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The side TOC will only include links for the current topic and its direct children.
- **all** - The side TOC will include all links.

webhelp.side.toc.tooltip.position

By default, if a topic contains a `shortdesc` element, its content is displayed in a tooltip when the user hovers over its link in the side table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 2.

Customizing the WebHelp Responsive Output on page 1175
WebHelp Responsive System on page 1153

WebHelp Responsive with Feedback Output

To publish a *DITA map* as a **WebHelp Responsive with Feedback** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Responsive with Feedback** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Templates Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.

- *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
- *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
- *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
- *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to begin the transformation.
5. Enter the documentation product ID (value for the `webhelp.product.id` parameter) and the documentation version (value for the `webhelp.product.version` parameter).

   When the **DITA Map WebHelp Responsive with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the *instructions to complete the system deployment*.

Parameters for Customizing WebHelp Responsive with Feedback Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is no).

editlink.remote.ditamap.url

Use this parameter in conjunction with `editlink.web.author.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the *main DITA map*. For example, a GitHub custom URL might look like this: `https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap`.

editlink.web.author.url

This parameter needs to be used in conjunction with `editlink.remote.ditamap.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the URL of the Web Author installation. For example: `https://www.oxygenxml.com/webapp-demo-aws/app/oxygen.html`.

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.enable.pagination

Specifies whether or not search results will be displayed on multiple pages. Allowed values are `yes` or `no`.

webhelp.search.page.numberOfItems

Specifies the number of search results items displayed on each page. This parameter is only used when the **webhelp.search.enable.pagination** parameter is enabled.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is `no`.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

Parameters Specific to WebHelp Responsive with Feedback Output

webhelp.default.collection.type

Specifies if the **sequence** value will be used by default when the `collection-type` attribute is not specified. This option is helpful if you want to have *Next* and *Previous* navigational buttons generated for all HTML pages. Allowed values are **no** (default) and **yes**.

webhelp.enable.search.autocomplete

Specifies if the *Autocomplete* feature is enabled in the WebHelp search text field. The default value is `yes`.

webhelp.fragment.after.body

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.logo_and_title

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.main.page.search

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.toc_or_tiles

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.top_menu

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.logo_and_title

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.page.search

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.toc_or_tiles

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.top_menu

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.head

In the generated output it inserts a given XHTML fragment in the `<head>` element. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.welcome

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, *Related Tasks*, *Related References*, *Related Information*) are merged into a single group. The default value is `yes`.

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is `yes`.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is `no`.

webhelp.show.indexterms.link

Specifies if an icon that links to the index will be presented in the output. The default value is `yes`.

webhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a *tree* style layout, this parameter should be set to no.

webhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is `yes`.

webhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is `yes`.

webhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is `yes`.

webhelp.show.related.links

Specifies if the related links component will be presented in the WebHelp Responsive output. The default value is `yes`. The webhelp.merge.nested.topics.related.links parameter can used in conjunction with this one to merge the related links from nested topics into the links in the parent topic.

webhelp.show.side.toc

Specifies if a side table of contents will be presented on the right side of each topic in the output. The default value is `yes`.

webhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is `yes`.

webhelp.side.toc.links

Specifies which links will be included in the side table of contents. The possible values are:

- **chapter** (default) - The side TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The side TOC will only include links for the current topic and its direct children.
- **all** - The side TOC will include all links.

webhelp.side.toc.tooltip.position

By default, if a topic contains a `shortdesc` element, its content is displayed in a tooltip when the user hovers over its link in the side table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 2.

WebHelp Classic Output

To publish a *DITA map* as a **WebHelp Classic** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Classic** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Skins Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.

- *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
- *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
- *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
- *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to process the transformation.

   When the **DITA Map WebHelp Classic** transformation is complete, the output is automatically opened in your default browser.

To further customize this transformation, you can edit various parameters, including the following most commonly used ones:

Parameters for Customizing WebHelp Classic Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.body.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<body>` section of every WebHelp page.

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
```

```
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.google.search.results

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (*iframe*) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

webhelp.google.search.script

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

webhelp.head.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<head>` section of every WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*,

appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

WebHelp Classic With Feedback Output

To publish a *DITA map* as a **WebHelp Classic with Feedback** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Classic with Feedback** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Skins Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.
   - *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
   - *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
   - *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
   - *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.
4. Click **Apply associated** to begin the transformation.
5. Enter the documentation product ID (value for the `webhelp.product.id` parameter) and the documentation version (value for the `webhelp.product.version` parameter).

   When the **DITA Map WebHelp Classic with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the *instructions to complete the system deployment*.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

Parameters for Customizing WebHelp Classic with Feedback Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.body.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<body>` section of every WebHelp page.

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
   </script>
   <div data-share="true" data-show-faces="true" data-action="like"
      data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.google.search.results

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (*iframe*) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

webhelp.google.search.script

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

webhelp.head.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<head>` section of every WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

WebHelp Classic Mobile Output

To publish a *DITA map* as a **WebHelp Classic Mobile** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Classic Mobile** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

- *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
- *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
- *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
- *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to process the transformation.

   When the **DITA Map WebHelp Classic Mobile** transformation is complete, the output is automatically opened in your default browser.

Parameters for Customizing WebHelp Classic Mobile Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
```

```
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.google.search.results

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (*iframe*) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

webhelp.google.search.script

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

webhelp.head.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<head>` section of every WebHelp page.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

DITA Map to PDF Output Customization

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting *DITA maps* to PDF output. There are numerous ways that you can customize the PDF output and the topics in this section discuss some of those possibilities.

Creating a DITA Map to PDF Transformation Scenario

To create a *DITA Map to PDF* transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF** and click the **Edit** button (or use the **Duplicate** button if your *framework* is read-only).
3. Use the various tabs to configure the transformation scenario. In the **Parameters** tab, you can use a variety of parameters to customize the output. For example, the following parameters are just a few of the most commonly used ones:
   - `show.changes.and.comments` - If set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output.
   - `customization.dir` - Specifies the path to a customization directory.
4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.

Customizing the PDF Output

DITA Open Toolkit PDF output can be customized in several ways:

- Creating a DITA Open Toolkit plugin that adds extensions to the PDF plugin. More details can be found in the *DITA Open Toolkit Documentation*.
- Creating a customization directory and using it from the PDF transformation scenario. A small example of this procedure can be found below.

How to Create a Customization Directory for PDF Output

The following procedure explains how to do a basic customization of the PDF output by setting up a customization directory. An example of a common use case is embedding a company logo image in the front matter of the book.

1. Copy the entire directory: *`DITA-OT-DIR`*`\plugins\org.dita.pdf2\Customization` to another location (for instance, `C:\Customization`).
2. Copy your logo image to: `C:\Customization\common\artwork\logo.png`.
3. Rename `C:\Customization\catalog.xml.orig` to: `C:\Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and *uncomment* this line:

   ```
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->
   ```

   It now looks like this:

   ```
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```
5. Rename the file: `C:\Customization\fo\xsl\custom.xsl.orig` to: `C:\Customization\fo\xsl\custom.xsl`
6. Open the `custom.xsl` file in Oxygen XML Editor and create the template called **createFrontCoverContents** for DITA-OT 2.5.2 (or createFrontMatter_1.0 for DITA-OT 1.8.5).

   Tip: You can copy the same template from *`DITA-OT-DIR`*`\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl` and modify it in whatever way necessary to achieve your specific goal. This new template in the `custom.xsl` file will override the same template from *`DITA-OT-DIR`*`\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl`.

   DITA OT 2.5.2 Example:

   For example, if you are using DITA OT 2.5.2, the `custom.xsl` could look like this:

   ```
   <?xml version='1.0'?>
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
       xmlns:fo="http://www.w3.org/1999/XSL/Format"
   ```

```
    version="2.0">

<xsl:template name="createFrontCoverContents">
 <!-- set the title -->
 <fo:block xsl:use-attribute-sets="__frontmatter__title">
  <xsl:choose>
   <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
    <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
      </xsl:when>
      <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
        <xsl:apply-templates select="$map//*[contains
                                      (@class,' bookmap/mainbooktitle ')][1]"/>
      </xsl:when>
      <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
        <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
      </xsl:when>
      <xsl:otherwise>
        <xsl:value-of select="/descendant::*[contains
          (@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
   </xsl:otherwise>
  </xsl:choose>
 </fo:block>

 <!-- set the subtitle -->
 <xsl:apply-templates select="$map//*[contains
                                     (@class,' bookmap/booktitlealt ')]"/>
 <fo:block xsl:use-attribute-sets="__frontmatter__owner">
  <xsl:apply-templates select="$map//*[contains(@class,' bookmap/bookmeta ')]"/>
 </fo:block>

 <!-- Load the image logo -->
  <fo:block text-align="center" width="100%">
   <fo:external-graphic
      src="url({concat($artworkPrefix,
                       '/Customization/OpenTopic/common/artwork/logo.png')})"
    />
  </fo:block>
 </xsl:template>

</xsl:stylesheet>
```

DITA OT 1.8.5 Example:

For example, if you are using DITA OT 1.8.5, the `custom.xsl` could look like this:

```
<?xml version='1.0'?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:fo="http://www.w3.org/1999/XSL/Format"
    version="1.1">

<xsl:template name="createFrontMatter_1.0">
   <fo:page-sequence master-reference="front-matter"
                        xsl:use-attribute-sets="__force__page__count">
     <xsl:call-template name="insertFrontMatterStaticContents"/>
       <fo:flow flow-name="xsl-region-body">
         <fo:block xsl:use-attribute-sets="__frontmatter">
     <!-- set the title -->
           <fo:block xsl:use-attribute-sets="__frontmatter__title">
            <xsl:choose>
             <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
     <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
                 </xsl:when>
    <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
     <xsl:apply-templates select="$map//*[contains
                                    (@class,' bookmap/mainbooktitle ')][1]"/>
         </xsl:when>
    <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
      <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
         </xsl:when>
      <xsl:otherwise>
    <xsl:value-of select="/descendant::*[contains
          (@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
      </xsl:otherwise>
         </xsl:choose>
     </fo:block>

  <!-- set the subtitle -->
     <xsl:apply-templates select="$map//*[contains
                                       (@class,' bookmap/booktitlealt ')]"/>

        <fo:block xsl:use-attribute-sets="__frontmatter__owner">
            <xsl:apply-templates select="$map//*[contains
                                              (@class,' bookmap/bookmeta ')]"/>
        </fo:block>

        <fo:block text-align="center" width="100%">
           <fo:external-graphic src="url({concat($artworkPrefix,
                        '/Customization/OpenTopic/common/artwork/logo.png')})"/>
         </fo:block>

    </fo:block>

   <!--<xsl:call-template name="createPreface"/>-->
```

```
            </fo:flow>
        </fo:page-sequence>
        <xsl:call-template name="createNotices"/>
    </xsl:template>
</xsl:stylesheet>
```

7. Edit the **DITA Map PDF** transformation scenario and in the **Parameters** tab, set the customization.dir parameter to `C:\Customization`.

Tip: For other specific examples, see *DITA-OT 2.x Documentation - PDF Customization Plugin*.

Customizing the Header and Footer in PDF Output

The XSLT stylesheet *DITA-OT-DIR*`/plugins/org.dita.pdf2/xsl/fo/static-content.xsl` contains templates that output the static header and footers for various parts of the PDF such as the prolog, table of contents, front matter, or body.

The templates for generating a footer for pages in the body are called `insertBodyOddFooter` or `insertBodyEvenFooter`.

These templates get the static content from resource files that depend on the language used for generating the PDF. The default resource file is *DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg/common/vars/en.xml`. These resource files contain variables (such as *Body odd footer*) that can be set to specific user values.

Instead of modifying these resource files directly, they can be overwritten with modified versions of the resources in a PDF customization directory as explained in *Customizing the PDF Output* on page 1897.

Adding a Watermark to PDF Output

To add a watermark to the PDF output of a *DITA map* transformation, create a DITA-OT customization directory and use it from a **DITA Map to PDF** transformation scenario, as in the following procedure:

1. Copy the entire directory: *DITA-OT-DIR*`\plugins\org.dita.pdf2\Customization` to another location (for instance, `C:\Customization`).
2. Copy your watermark image (for example, `watermark.png`) to: `C:\Customization\common\artwork\watermark.png`.
3. Rename the `C:\Customization\catalog.xml.orig` file to: `C:\Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and *uncomment* this line:

   ```
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->
   ```

   The uncommented line should look like this:

   ```
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```

5. Rename the file: `C:\Customization\fo\xsl\custom.xsl.orig` to: `C:\Customization\fo\xsl\custom.xsl`
6. Open the `C:\Customization\fo\xsl\custom.xsl` file in Oxygen XML Editor to overwrite two XSLT templates:
   - The first template is located in the XSLT stylesheet *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\static-content.xsl` and we override it specifying a watermark image for every page in the PDF content, using a *block-container* element that references the watermark image file:

     ```
     <fo:static-content flow-name="odd-body-header">
            <fo:block-container absolute-position="absolute"
               top="-2cm" left="-3cm" width="21cm" height="29.7cm"
               background-image="{concat($artworkPrefix,
     '/Customization/OpenTopic/common/artwork/watermark.png')}">
              <fo:block/>
            </fo:block-container>
           <fo:block xsl:use-attribute-sets="__body__odd__header">
               <xsl:call-template name="insertVariable">
                   <xsl:with-param name="theVariableID" select="'Body odd header'"/>
                   <xsl:with-param name="theParameters">
     ```

```
                <prodname>
                    <xsl:value-of select="$productName"/>
                </prodname>
                <heading>
              <fo:inline xsl:use-attribute-sets="__body__odd__header__heading">
                     <fo:retrieve-marker retrieve-class-name="current-header"/>
              </fo:inline>
               </heading>
              <pagenum>
            <fo:inline xsl:use-attribute-sets="__body__odd__header__pagenum">
                  <fo:page-number/>
            </fo:inline>
          </pagenum>
        </xsl:with-param>
      </xsl:call-template>
    </fo:block>
  </fo:static-content>

</xsl:template>
```

- The second template that we override is located in the XSLT stylesheet *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\commons.xsl` and is used for styling the first page of the output. We also override it by copying the original template content in our `custom.xsl` and adding the `block-container` element that references the watermark image file:

```
<xsl:template name="createFrontMatter_1.0">
      <fo:page-sequence master-reference="front-matter"
xsl:use-attribute-sets="__force__page__count">
          <xsl:call-template name="insertFrontMatterStaticContents"/>
          <fo:flow flow-name="xsl-region-body">
              <fo:block-container absolute-position="absolute"
                  top="-2cm" left="-3cm" width="21cm" height="29.7cm"
                  background-image="{concat($artworkPrefix,
'/Customization/OpenTopic/common/artwork/watermark.png')}">
                  <fo:block/>
              </fo:block-container>
  <fo:block xsl:use-attribute-sets="__frontmatter">
       <!-- set the title -->
    <fo:block xsl:use-attribute-sets="__frontmatter__title">
     <xsl:choose>
      <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
    <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
      </xsl:when>
      <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
    <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/mainbooktitle ')][1]"/>
          </xsl:when>
          <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
              <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
          </xsl:when>
            <xsl:otherwise>
             <xsl:value-of select="/descendant::*[contains
(@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
            </xsl:otherwise>
      </xsl:choose>
    </fo:block>

   <!-- set the subtitle -->
   <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/booktitlealt ')]"/>

      <fo:block xsl:use-attribute-sets="__frontmatter__owner">
         <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/bookmeta ')]"/>
      </fo:block>

      </fo:block>

   <!--<xsl:call-template name="createPreface"/>-->

      </fo:flow>
        </fo:page-sequence>
        <xsl:if test="not($retain-bookmap-order)">
            <xsl:call-template name="createNotices"/>
        </xsl:if>
    </xsl:template>
```

7. Edit your **DITA Map PDF** transformation scenario. In the **Parameters** tab, set the customization.dir parameter to `C:\Customization`.

Related Information:

Adding a Watermark in DITA Map to XHTML Output on page 1906

Adding an Edit Link in PDF Output to Launch Oxygen XML Web Author

You can embed *Edit* links in the DITA Map PDF output that will automatically launch a particular document in *Oxygen XML Web Author*. A reviewer can then simply click the link and they will be redirected to the Oxygen XML Web Author editing page with that particular file open and editable.

To embed an *Edit* link in the DITA Map PDF output, follow these steps:

1. *Edit a **DITA Map PDF** transformation scenario* and open the **Parameters** tab.
2. Set values for the following parameters:
   - **editlink.remote.ditamap.url** - The URL of the DITA Map suitable for opening in Oxygen XML Web Author.
   - **editlink.web.author.url** - The URL of the Oxygen XML Web Author installation.
3. Run the transformation scenario.

Result: In the PDF output, all topics will have an **Edit** link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

Force Page Breaks Between Two Block Elements in PDF Output

Suppose that in your DITA content you have two *block elements*, such as two paragraphs:

```
<p>First para</p>
<p>Second para</p>
```

and you want to force a page break between them in the PDF output.

Here is how you can implement a DITA Open Toolkit *plugin* that would achieve this:

1. Define your custom processing instruction that marks the place where a page break should be inserted in the PDF, for example:

   ```
   <p>First para</p>
     <?pagebreak?>
   <p>Second para</p>
   ```
2. Locate the **DITA Open Toolkit** distribution and in the `plugins` directory create a new *plugin* folder (for example, *`DITA-OT-DIR`*`/plugins/pdf-page-break`).
3. In this new folder, create a new `plugin.xml` file with the following content:

   ```
   <plugin id="com.yourpackage.pagebreak">
     <feature extension="package.support.name" value="Force Page Break Plugin"/>
     <feature extension="package.support.email" value="support@youremail.com"/>
     <feature extension="package.version" value="1.0.0"/>
     <feature extension="dita.xsl.xslfo" value="pageBreak.xsl" type="file"/>
   </plugin>
   ```

   The most important feature in the *plugin* is that it will add a new XSLT stylesheet to the XSL processing that produces the PDF content.
4. In the same folder, create an XSLT stylesheet named `pageBreak.xsl` with the following content:

   ```
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                   xmlns:fo="http://www.w3.org/1999/XSL/Format"version="1.0">
     <xsl:template match="processing-instruction('pagebreak')">
       <fo:block break-after="page"/>
     </xsl:template>
   </xsl:stylesheet>
   ```
5. *Install your plugin in the DITA Open Toolkit.*

Customizing `note` Images in PDF

To customize the images that appear next to each type of note in the PDF output, use a *PDF customization folder* with the following procedure:

1. Copy the *`DITA-OT-DIR`*`/plugins/org.dita.pdf2/cfg/common/vars/en.xml` file to the `[CUSTOMIZATION_DIR]\common\vars` folder.
2. Edit the copied `en.xml` file and modify, for example, the path to the image for `<note>` element with the `type` attribute set to `notice` from:

   ```
   <variable id="notice Note Image
     Path">Configuration/OpenTopic/cfg/common/artwork/important.png</variable>
   ```

to:

```
<variable id="notice Note Image
  Path">Customization/OpenTopic/common/artwork/notice.gif</variable>
```

3. Add your custom **notice** image to `[CUSTOMIZATION_DIR]\common\artwork\notice.gif`.
4. Edit the **DITA Map PDF** transformation scenario and in the **Parameters** tab set the path for the customization.dir property to point to the customization folder. Also, set the **com.oxygenxml.use.custom.note.images** parameter to **no**.

Show Comments and Tracked Changes in PDF Output

To include comments and *tracked changes* (stored within your DITA topics) in the PDF output, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF** and click the **Edit** button (or use the **Duplicate** button if your *framework* is read-only).
3. In the **Parameters** tab, set the value of the show.changes.and.comments parameter to `yes`.
4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.

   Result: Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

Set a Font for PDF Output Generated with FO Processor

When a *DITA map* is transformed to PDF using an FO processor and it contains some Unicode characters that cannot be rendered by the default PDF fonts, a font that is capable of rendering these characters must be configured and embedded in the PDF result.

The settings that must be modified for configuring a font for the built-in FO processor are detailed in *Add a Font to the Built-in FO Processor*.

DITA OT PDF Font Mapping

The DITA OT contains a file *`DITA-OT-DIR`*`/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml` that maps logical fonts used in the XSLT stylesheets to physical fonts that will be used by the FO processor to generate the PDF output.

The XSLT stylesheets used to generate the XSL-FO output contain code like this:

```
<xsl:attribute name="font-family">monospace</xsl:attribute>
```

The font-family is defined to be *monospace*, but *monospace* is just an alias. It is not a physical font name. Therefore, another stage in the PDF generation takes this *monospace* alias and looks in the `font-mappings.xml`.

If it finds a mapping like this:

```
<aliases>
      <alias name="monospace">Monospaced</alias>
 </aliases>
```

then it looks to see if the *Monospaced* has a *logical-font* definition and if so, it will use the *physical-font* specified there:

```
<logical-font name="Monospaced">
      <physical-font char-set="default">
        <font-face>Courier New, Courier</font-face>
      </physical-font>
.............
</logical-font>
```

Important:

If no alias mapping is found for a font-family specified in the XSLT stylesheets, the processing defaults to **Helvetica**.

Related Information:

DITA Map to PDF WYSIWYG Transformation

Oxygen XML Editor comes bundled with a DITA OT plugin that allows you to convert *DITA maps* to PDF using a CSS layout processor. Oxygen XML Editor also comes bundled with a built-in CSS-based PDF processing engine called **Chemistry**. For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations.

Oxygen XML Editor supports the following processors (not included in the Oxygen XML Editor installation kit):

- **Oxygen Chemistry** - A built-in processor that is bundled with Oxygen XML Editor. For more information, see the *Oxygen PDF Chemistry User Guide*.
- **Prince Print with CSS** - A third-party component that needs to be purchased from *http://www.princexml.com*.
- **Antenna House Formatter** - A third-party component that needs to be purchased from *http://www.antennahouse.com/antenna1/formatter/*.

The DITA-OT plugin is located in the following directory: *`DITA-OT-DIR`*`/plugins/com.oxygenxml.pdf.css`.

Although it includes a set of CSS files in its `css` subfolder, when this plugin is used in Oxygen XML Editor, the CSS files located in the `${frameworks}` directory take precedence.

Creating the Transformation Scenario

To create an **DITA Map to PDF WYSIWYG** transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF - WYSIWYG**.
3. In the **CSS Processor** tab, choose the processor type. You can select between **Oxygen PDF Chemistry**, **Prince XML**, or **Antenna House**.
4. In the **Parameters** tab, configure any of the following parameters (if applicable):
   - `css.processor.path.prince` (if you are using the **Prince Print with CSS** processor) - Specifies the path to the Prince executable file that will be run to produce the PDF. If you installed Prince using its default settings, you can leave this blank.
   - `css.processor.path.antenna-house` (if you are using the **Antenna House Formatter** processor) - Specifies the path to the Antenna House executable file that will be run to produce the PDF. If you installed Antenna House using its default settings, you can leave this blank.
   - `show.changes.and.comments` - When set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output. The default value is no.
   - `dita.css.list` - Allows you to specify a list of CSS URLs to be used by the PDF processor (instead of the default CSS files). The files must have URL syntax and be separated using semicolons. If the value is empty, the CSS associated with the current selection from the **Styles** drop-down menu is used.
   - `args.css` - Allows you to specify a list of CSS URLs to be used in addition to those specified in the `dita.css.list` parameter OR in addition to the CSS that is currently selected in the **Styles** drop-down menu. The files must have URL syntax and be separated using semicolons. Also, the `dita.css.list` parameter must be left empty to use these files in addition to the selection in the **Styles** drop-down menu.
5. Click **OK** and run the transformation scenario.

Customizing the Styles (for Output and Editing)

If you need to change the styles in the associated CSS, make sure you install Oxygen XML Editor in a folder where you have full read and write privileges (for instance, your user home directory). This is due to the fact that the installed files are usually placed in a read-only folder (for instance, in Windows, Oxygen XML Editor is installed in the `Program Files` folder where the users do not have change rights).

To change the styles of an element you need to create an additional CSS file that will store the customization rules. Once you have created this file, you need to instruct the editor how to use this additional CSS. This can be done in two ways:

- Create an alternate CSS for the DITA document type:
  1. Follow the procedure for adding an alternate CSS file in *Customizing the Main CSS of a Framework* on page 1454.

2. Once you have configured your CSS as an additional layer, you can *select it from the **Styles** drop-down menu (on the toolbar)*.
3. Run the **DITA Map PDF - WYSIWYG** transformation scenario and the customization rules from the additional CSS will be visible in the produced PDF.

This method allows you to have many customization CSS files and simply select the one that you need at any time for both the output and rendering **Author** mode while editing.

- Use the `args.css` parameter that allows you to specify a list of CSS URLs to be used in addition to the `dita.css.list` parameter:

1. Configure a **DITA map to PDF WYSIWYG** transformation scenario, as described in the procedure *above*.
2. In the **Parameters** tab, specify the path to your custom CSS files in the `args.css` parameter.
3. Click **OK** and run the transformation scenario.

This method is appropriate if you just want to apply the styling customization to the output.

Tip: For more information about customizing CSS styles for PDF output, see the *Oxygen PDF Chemistry User Guide*. It offers numerous tips for customizing CSS styles even if you are not using the Chemistry processor.

Using the CSS Inspector to See Style Associated with an Element

To find the styles associated with an element, follow this procedure:

1. Open a document in the editor and select **Inspect Styles** from the contextual menu. This opens the ***CSS Inspector** view* that shows all the CSS rules that apply to the selected element.
2. Click the particular link for the CSS selector that you need to change and Oxygen XML Editor will open the CSS file and position the cursor at that selector.
3. After you identify the source of the styles you want to modify, copy the CSS rule in your customization CSS file and modify it according to your needs.

   To see the changes in **Author** mode, press **F5** to reload the document.

How to Make Remote Resources Appear in the Output When Using the Prince Processor

If your documentation references external resources (such as images that are stored on a Web-based repository) and your system is behind an HTTP(S) proxy, you may find that they do not appear in the output when using the **Prince Print with CSS** processor. To solve this, follow this procedure:

1. Edit the **`build.xml`** file that is located in *`DITA-OT-DIR`*`/plugins/com.oxygenxml.pdf.css`.
2. There are two instances in the file where a pair of arguments are commented out:

```
<!-- Please remove the comment wrapping the following two arguments
if you are behind a proxy and your documentation refers remote resources,
for example images.

Note: You also need to remove the backslash '\' that appears before the
property name: "http-proxy". That backslash is there because a sequence of
two dashes ('-') is not permited inside a comment.
-->
<!--
  <arg value="-\-http-proxy=${http.proxyHost}:${http.proxyPort}"/>
  <arg value="-\-http-proxy=${https.proxyHost}:${https.proxyPort}"/>
-->
```

3. Remove the comment in both instances.
4. Make sure you also remove the slash that appears before the property name `http-proxy` in each instance.

   Step Result: The arguments should now look like this:

```
<arg value="--http-proxy=${http.proxyHost}:${http.proxyPort}"/>
<arg value="--http-proxy=${https.proxyHost}:${https.proxyPort}"/>
```

5. Save the **`build.xml`** file.
6. Run the *DITA map to PDF WYSIWYG transformation scenario*.

   Result: Your external resources should now appear in your output.

Customizing CSS Styles Using Oxygen PDF Chemistry

Oxygen PDF Chemistry makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations. It allows you to style the PDF output by simply changing the CSS and then re-running the transformation scenario until you get the desired result.

For more information, see the *Oxygen PDF Chemistry User Guide*. It also offers numerous tips for customizing CSS styles for PDF output even if you are not using the Chemistry processor.

DITA Map to MS Office Word Transformation

Oxygen XML Editor comes bundled with a transformation scenario that allows you to convert *DITA maps* to Microsoft Office Word documents. It utilizes the ***DITA to Word plugin*** *created by Jarno Elovirta*. This *plugin* contains a Word document named **Normal.docx** (located in: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/DITA-OT2.x/plugins/com.elovirta.ooxml/resources`) that is used by the transformation scenario as a template to generate the final Word document.

Tip: You can make general modifications to the **Normal.docx** template file to alter the published output.

Configuring the Transformation Scenario

To configure an **DITA Map to MS Office Word** transformation scenario, follow these steps:

1. Open the DITA map in the ***DITA Maps Manager***.
2. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
3. Select **DITA Map MS Office Word**.
4. For advanced customizations, in the **Parameters** tab you can use any of the following parameters that are unique to this transformation scenario to specify paths to files that affect the output in various ways:
   - `dotx.file` - Specifies the path to a Word template file (`.docx`) that will be used in the transformation to generate the final Word document. Set this parameter if you want to use a different template file other than the **Normal.docx** file that is used by default.
   - `document.flat.xsl` - Specifies the path to a pre-process clean-up stylesheet.
   - `core.xsl` - Specifies the path to a core metadata stylesheet.
   - `custom.xsl` - Specifies the path to a custom metadata stylesheet.
   - `document.xsl` - Specifies the path to a main document stylesheet.
   - `comments.xsl` - Specifies the path to a comments stylesheet.
   - `numbering.xsl` - Specifies the path to a list and title numbering stylesheet.
   - `footnotes.xsl` - Specifies the path to a footnote stylesheet.
   - `document.xml.xsl` - Specifies the path to a document relations metadata stylesheet.
   - `inkscape.exec` - Specifies the path to an Inkscape (open-source vector graphics editor) executable file.
5. Click **OK** and run the transformation scenario.

Result: The result of the transformation will automatically be opened in your system's default word processing application (such as Microsoft Word).

Migrating MS Office Documents to DITA on page 1930

Compiled HTML Help (CHM) Output Format

To perform a *Compiled HTML Help (CHM)* transformation, Oxygen XML Editor needs `Microsoft HTML Help Workshop` to be installed on your computer. Oxygen XML Editor automatically detects `HTML Help Workshop` and uses it.

Note: `HTML Help Workshop` might fail if the files used for transformation contain accents in their names, due to different encodings used when writing the *.hhp* and *.hhc* files. If the transformation fails to produce the CHM output but the *.hhp* (HTML Help Project) file is already generated, you can manually try to build the CHM output using `HTML Help Workshop`.

Changing the Output Encoding

Oxygen XML Editor uses the `htmlhelp.locale` parameter to correctly display specific characters of different languages in the output of the *Compiled HTML Help (CHM)* transformation. By default, the **DITA Map CHM** transformation scenario that comes bundled with Oxygen XML Editor has the `htmlhelp.locale` parameter set to `en-US`.

To customize this parameter, follow this procedure:

1. Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
2. Select the **DITA Map CHM** transformation scenario and click the **Edit** button.
3. In the **Parameter** tab, search for the `htmlhelp.locale` parameter and change its value to the desired language tag.

   Note: The format of the `htmlhelp.locale` parameter is `LL-CC`, where `LL` represents the language code (`en`, for example) and `CC` represents the country code (`US`, for example). The language codes are contained in the `ISO 639-1` standard and the country codes are contained in the `ISO 3166-1` standard. For further details about language tags, go to *http://www.rfc-editor.org/rfc/rfc5646.txt*.

Kindle Output Format

Oxygen XML Editor requires KindleGento generate Kindle output from *DITA maps*. To install KindleGen for use by Oxygen XML Editor, follow these steps:

1. Go to *www.amazon.com/kindleformat/kindlegen* and download the zip file that matches your operating system.
2. Unzip the file on your local disk.
3. Start Oxygen XML Editor and open a *DITA map* in the ***DITA Maps Manager** view*.
4. Click the **Configure Transformation Scenario(s)** button.
5. Select the **DITA Map Kindle** transformation and press the **Edit** button to edit it.
6. Go to **Parameters** tab and set the **kindlegen.executable** parameter as the path to the *KindleGen* directory.
7. Accept the changes.

XHTML Document Type (Framework)

The Extensible HyperText Markup Language (XHTML), is a markup language that has the same depth of expression as HTML, but also conforms to XML syntax.

File Definition

A file is considered to be an XHTML document when the root element name is `html`.

Default Document Templates

There are a variety of default *XHTML* templates available when creating *new documents from templates* and they can be found in: **Framework Templates** > **XHTML**.

The default templates for XHTML documents are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml/templates/` folder.

Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the XHTML file are stored in the following locations:

- XHTML 1.0 - *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml/dtd/` or *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml/nvdl/`.
- XHTML 1.1 - *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml11/dtd/` or *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml11/schema/`.
- XHTML 5 - *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml/xhtml5 (epub3)/`.

Default CSS

The default CSS files used for rendering XHTML content in **Author** mode are stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalogs

The default *XML Catalogs* for the XHTML document type are as follows:

- *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml/dtd/xhtmlcatalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/frameworks/relaxng/catalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/frameworks/nvdl/catalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml11/dtd/xhtmlcatalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/frameworks/xhtml11/schema/xhtmlcatalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/xhtml5 (epub3)/catalog-compat.xml`

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform XHTML documents to several types of DITA document types (topic, task, concept, reference). They can be found in the **XHTML** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

XHTML Author Mode Actions

A variety of actions are available in the XHTML *framework* that can be added to the **XHTML** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

XHTML Toolbar Actions

The following default actions are readily available on the **XHTML (Author Custom Actions)** toolbar when editing in **Author** mode (by default, they are also available in the **XHTML** menu and some of them are in various submenus of the contextual menu):

B **Bold**

Changes the style of the selected text to `bold` by surrounding it with b tag. You can use this action on multiple non-contiguous selections.

Italic

Changes the style of the selected text to `italic` by surrounding it with `i` tag. You can use this action on multiple non-contiguous selections.

Underline

Changes the style of the selected text to `underline` by surrounding it with u tag. You can use this action on multiple non-contiguous selections.

Link

Inserts an a element with an `href` attribute at the cursor position. You can type the URL of the reference you want to insert or use the **Browse** drop-down menu to select it using one of the following options:

- **Browse for local file** - Displays the **Open** dialog box to select a local file.
- **Browse for remote file** - Displays the ***Open URL*** *dialog box* to select a remote file.
- **Browse for archived file** - Opens the ***Archive Browser*** to select a file from an archive.
- **Browse Data Source Explorer** - Open the ***Data Source Explorer*** to select a file from a connected data source.
- **Search for file** - Opens the ***Find Resource*** *dialog box* to search for a file.

Insert Image

Inserts a graphic object at the cursor position. This is done by inserting an `img` element regardless of the current context. The following graphical formats are supported: GIF, JPG, JPEG, BMP, PNG, SVG.

Insert Media Resource

Opens a ***Choose Media*** *dialog box* that allows you to select the URL of a media object to be inserted into a document at the cursor position. The result will be that a reference to the specified video, audio, or embedded HTML frame is inserted and rendered in **Author** mode so that it can be played directly from there.

Headings Drop-down Menu

A drop-down menu that includes actions for inserting h1, h2, h3, h4, h5, h6 elements.

Insert Paragraph

Insert a new paragraph element at current cursor position.

Insert Equation

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

Insert List Item

Inserts a list item in the current list type.

Insert Unordered List

Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert a definition list at the cursor position

Inserts a definition list (`dl` element) with one list item (a `dt` child element and a `dd` child element). You can also use this action to convert selected paragraphs or other types of lists to a definition list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content — text + markup — that is

rendered inside a *block element*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Column After

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

XHTML Menu Actions

In addition, the following default actions are available in the **XHTML** menu when editing in **Author** mode (some of them are also available in the contextual menu):

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Insert Column Before

Inserts a column before the current one.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

XHTML Contextual Menu Actions

In addition to many of the *XHTML toolbar actions* and the *general* ***Author*** *mode contextual menu actions*, the following XHTML *framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

XHTML Drag/Drop (or Copy/Paste) Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into an XHTML document that is edited in **Author** mode, creates a link to the dragged file (the a element with the `href` attribute) at the drop location. Copy and paste actions work the same.

You can also drag images or media files from your system explorer or the ***Project*** *view* and drop them into an XHTML document (or copy and paste). This will insert the appropriate element at the drop or paste location (for example, dropping/pasting an image will insert the `img` element with the `src` attribute).

TEI P5 Document Type (Framework)

The *TEI (Text Encoding Initiative)* document type is an international and interdisciplinary standard that enables libraries, museums, publishers, and individual scholars to represent a variety of literary and linguistic texts for online research, teaching, and preservation.

File Definition

A file is considered to be a TEI P5 document when one of the following conditions are true:

- The document namespace is *http://www.tei-c.org/ns/1.0*.
- The public ID of the document is *-//TEI P5*.

Default Document Templates

There are a variety of default *TEI P5* templates available when creating *new documents from templates* and they can be found in: **Framework Templates** > **TEI P5**.

The default templates for TEI P5 documents are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/templates/TEI P5` folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected in the TEI P5 document is `tei_all.rng` and it is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/custom/schema/relaxng/`.

Default CSS

The default CSS files used for rendering TEI content in **Author** mode are stored in *[OXYGEN_INSTALL_DIR]*/frameworks/tei/xml/tei/css/.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalogs

The default *XML Catalogs* for the TEI P5 document type are as follows:

- *[OXYGEN_INSTALL_DIR]*/frameworks/tei/xml/tei/schema/dtd/catalog.xml
- *[OXYGEN_INSTALL_DIR]*/frameworks/tei/xml/tei/custom/schema/dtd/catalog.xml
- *[OXYGEN_INSTALL_DIR]*/frameworks/tei/xml/tei/stylesheet/catalog.xml

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform TEI P5 documents to a variety of outputs, such as PDF, XHTML, EPUB, DOCX, and ODT. They can be found in the **TEI P5** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

Adding Tables in TEI Documents on page 615

TEI P5 Author Mode Actions

A variety of actions are available in the TEI P5 *framework* that can be added to the **TEI P5** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

TEI P5 Toolbar Actions

The following default actions are readily available on the **TEI P5 (Author Custom Actions)** toolbar when editing in **Author** mode (by default, they are also available in the **TEI P5** menu and some of them are in various submenus of the contextual menu):

Bold

Changes the style of the selected text to `bold` by surrounding it with `hi` tag and setting the `rend` attribute to `bold`. You can use this action on multiple non-contiguous selections.

Italic

Changes the style of the selected text to `italic` by surrounding it with `hi` tag and setting the `rend` attribute to `italic`. You can use this action on multiple non-contiguous selections.

Underline

Changes the style of the selected text to `underline` by surrounding it with `hi` tag and setting the `rend` attribute to `ul`. You can use this action on multiple non-contiguous selections.

Insert Section

Inserts a new section or subsection, depending on the current context. For example, if the current context is `div1`, then a `div2` is inserted. By default, this action also inserts a paragraph element as a child node.

Insert Paragraph

Insert a new paragraph element at current cursor position.

Insert Image

Inserts an image reference at the cursor position. Depending on the current location, an image-type element is inserted.

Insert List Item

Inserts a list item in the current list type.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert Itemized List

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

Sort

Sorts cells or list items in a table.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content — text + markup — that is rendered inside a *block element*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Insert Column After

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

TEI P5 Menu Actions

In addition, the following default actions are available in the **TEI P5** menu when editing in **Author** mode (some of them are also available in the contextual menu):

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Insert Column Before

Inserts a column before the current one.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is *cut* and *pasted*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

TEI Contextual Menu Actions

In addition to many of the *TEI toolbar actions* and the *general* ***Author*** *mode contextual menu actions*, the following TEI *framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Image Map Editor

This action is available in the contextual menu when it is invoked on an image. This action applies an *image map* to the current image (if one does not already exist) and opens the **Image Map Editor** dialog box. This feature allows you to create hyperlinks in specific areas of an image that will link to various destinations.

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

Sort

Sorts cells or list items in a table.

Table Properties

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

TEI P5 Drag/Drop Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a TEI P5 document that is edited in **Author** mode, creates a link to the dragged file (the `ptr` element with the `target` attribute) at the drop location. Dragging an image file from the default file system application (Windows Explorer on Windows or Finder on Mac OS X, for example) and dropping it into a TEI P5 document inserts a graphic element (the `graphic` element with the `url` attribute) at the drop location, similar to the **Insert Image** toolbar action.

Customization of TEI Frameworks Using the Latest Sources

The *TEI P5 framework* is available as a public project at the following SVN repository: *https://github.com/TEIC/oxygen-tei*. This project is the base for customizing a TEI *framework*.

To customize a TEI *framework*, follow this procedure:

1. Check out the project on a local computer from the SVN repository.

   This action is done with an SVN client application that creates a working copy of the SVN repository on a local computer.
2. Customize the TEI *framework* in Oxygen XML Editor.
   a) Set the Oxygen XML Editor `frameworks` folder to the `oxygen/frameworks` subfolder of the folder of the SVN working copy.

      Open the ***Preferences*** *dialog box* ***(Options > Preferences)***, go to **Global**, and set the path of the SVN working copy in the **Use custom frameworks** option.
   b) *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)***, go to **Document Type Association** > **Locations**, and select **Custom**.
3. Build a *JAR* file with the TEI *framework*.

   The SVN project includes a `build.xml` file that can be used for building a *JAR* file using the Ant tool. The command that should be used:

   ```
   ant -f build.xml
   ```
4. Distribute the *JAR* file to the users that need the customized TEI *framework*.

   The command from the above step creates a file `tei.zip` in the `dist` subfolder of the SVN project. Each user that needs the customized TEI *framework* will receive the `tei.zip` file and will unzip it in the `frameworks` folder of the Oxygen XML Editor install folder.

Customization of TEI Frameworks Using the Compiled Sources

The following procedure describes how to update to the latest stable version of TEI Schema and TEI XSL, already integrated in the TEI *framework* for Oxygen XML Editor.

1. Go to *https://code.google.com/p/oxygen-tei/*;
2. Go to **Downloads**;

3. Download the latest uploaded `.zip` file;
4. Unpack the `.zip` file and copy its content in the Oxygen XML Editor `frameworks` folder.

TEI ODD Document Type (Framework)

The *TEI ODD (Text Encoding Initiative - One Document Does it all)* document type is a TEI XML-conformant specification format that allows you to create a custom TEI P5 schema in a literate programming fashion. A system of XSLT stylesheets called *Roma* was created by the TEI Consortium for manipulating the ODD files.

File Definition

A file is considered to be a TEI ODD document when the following conditions are true:

- The file extension is `.odd`.
- The document namespace is *http://www.tei-c.org/ns/1.0*.

Default Document Templates

There is a default *TEI ODD* document template available when creating *new documents from templates* and they can be found in: **Framework Templates** > **TEI ODD**.

The default template is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/templates/TEI ODD` folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected in the TEI ODD document is `tei_odds.rng` and it is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/custom/schema/relaxng/`.

Default CSS

The default CSS files used for rendering TEI ODD content in **Author** mode are stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalogs

The default *XML Catalogs* for the TEI ODD document type are as follows:

- *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/custom/schema/catalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/schema/catalog.xml`

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform TEI ODD documents to a variety of outputs, such as PDF, XHTML, EPUB, DOCX, ODT, RNG, DTD, and XML Schema. They can be found in the **TEI ODD** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

Editing XML Documents in Text Mode on page 492

TEI ODD Author Mode Actions

A variety of actions are available in the TEI ODD *framework* that can be added to the **TEI ODD** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

TEI ODD Toolbar Actions

The following default actions are readily available on the **TEI ODD (Author Custom Actions)** toolbar when editing in **Author** mode (by default, they are also available in the **TEI ODD** menu and some of them are in various submenus of the contextual menu):

Bold

Changes the style of the selected text to `bold` by surrounding it with `hi` tag and setting the `rend` attribute to `bold`. You can use this action on multiple non-contiguous selections.

Italic

Changes the style of the selected text to `italic` by surrounding it with `hi` tag and setting the `rend` attribute to `italic`. You can use this action on multiple non-contiguous selections.

Underline

Changes the style of the selected text to `underline` by surrounding it with `hi` tag and setting the `rend` attribute to `ul`. You can use this action on multiple non-contiguous selections.

Insert Section

Inserts a new section or subsection, depending on the current context. For example, if the current context is `div1`, then a `div2` is inserted. By default, this action also inserts a paragraph element as a child node.

Insert Paragraph

Insert a new paragraph element at current cursor position.

Insert Image

Inserts an image reference at the cursor position. Depending on the current location, an image-type element is inserted.

Insert List Item

Inserts a list item in the current list type.

Insert Ordered List

Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Insert Itemized List

Inserts an itemized list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an itemized list.

Insert Table

Opens a dialog box that allows you to configure and insert a table. You can generate a header and footer, set the number of rows and columns of the table and decide how the table is framed. You can also use this action to convert selected paragraphs, lists, and inline content (mixed content — text + markup — that is rendered inside a *block element*) into a table, with the selected content inserted in the first column, starting from the first row after the header (if a header is inserted).

Note: If the selection contains a mixture of elements that cannot be converted, you will receive an error message saying that **Only lists, paragraphs, or inline content can be converted to tables**.

Insert Row Below

Inserts a new table row with empty cells below the current row. This action is available when the cursor is positioned inside a table.

Insert Column After

Inserts a new table column with empty cells after the current column. This action is available when the cursor is positioned inside a table.

Insert Cell

Inserts a new empty cell depending on the current context. If the cursor is positioned between two cells, Oxygen XML Editor a new cell at cursor position. If the cursor is inside a cell, the new cell is created after the current cell.

Delete Column(s)

Deletes the table column located at cursor position or multiple columns in a selection.

Delete Row(s)

Deletes the table row located at cursor position or multiple rows in a selection.

Join Cells

Joins the content of the selected cells (both horizontally and vertically).

Split Cell

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

TEI ODD Menu Actions

In addition, the following default actions are available in the **TEI ODD** menu when editing in **Author** mode (some of them are also available in the contextual menu):

Table submenu

In addition to the table actions available on the toolbar, the following actions are available in this submenu:

Insert Row Above

Inserts a new table row with empty cells above the current row. This action is available when the cursor is positioned inside a table.

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

Insert Column Before

Inserts a column before the current one.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

ID Options

Opens the **ID Options** dialog box that allows you to configure options for generating IDs in **Author** mode. The dialog box includes the following:

ID Pattern

The pattern for the ID values that will be generated. This text field can be customized using constant strings or any of the Oxygen XML Editor *Editor Variables*.

Element name or class value to generate ID for

The elements for which ID values will be generated, specified using class attribute values. To customize the list, use the **Add**, **Edit**, or **Remove** buttons.

Auto generate IDs for elements

If selected, Oxygen XML Editor will automatically generate unique IDs for the elements listed in this dialog box when they are created in **Author** mode.

Remove IDs when copying content in the same document

When copying and pasting content in the same document, this option allows you to control whether or not pasted elements that are listed in this dialog box should retain their existing IDs. To retain the element IDs, deselect this option.

Note: This option does not have an effect on content that is *cut* and *pasted*.

Generate IDs

Oxygen XML Editor generates unique IDs for the current element (or elements), depending on how the action is invoked:

- When invoked on a single selection, an ID is generated for the selected element at the cursor position.
- When invoked on a block of selected content, IDs are generated for all top-level elements and elements from the list in the **ID Options** dialog box that are found in the current selection.

Note: The **Generate IDs** action does not overwrite existing ID values. It only affects elements that do not already have an `id` attribute.

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

TEI Contextual Menu Actions

In addition to many of the *TEI toolbar actions* and the *general* ***Author*** *mode contextual menu actions*, the following TEI *framework*-specific actions are also available in the contextual menu when editing in **Author** mode:

Table Actions

The following table editing actions are available in the contextual menu when it is invoked on a table:

Insert Rows

Opens a dialog box that allows you to insert any number of rows and specify the position where they will be inserted (**Above** or **Below** the current row).

 **Delete Row(s)**

Deletes the table row located at cursor position or multiple rows in a selection.

Insert Columns

Opens a dialog box that allows you to insert any number of columns and specify the position where they will be inserted (**Above** or **Below** the current column).

 **Delete Column(s)**

Deletes the table column located at cursor position or multiple columns in a selection.

 **Join Cells**

Joins the content of the selected cells (both horizontally and vertically).

 **Split Cell**

Splits the cell at the cursor location. If Oxygen XML Editor detects more than one option to split the cell, a dialog box will be displayed that allows you to select the number of rows or columns to split the cell into.

 **Sort**

Sorts cells or list items in a table.

 **Table Properties**

Opens the **Table properties** dialog box that allows you to configure properties of a table (such as frame borders).

Other Actions submenu

This submenu give you access to all the usual contextual menu actions.

TEI ODD Drag/Drop Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a TEI ODD document that is edited in **Author** mode, creates a link to the dragged file (the `ptr` element with the `target` attribute) at the drop location.

jTEI Document Type (Framework)

The *jTEI (Journal of the Text Encoding Initiative)* document type is highly restrictive customization (only about 80 elements are included) of the TEI P5 *framework*.

File Definition

A file is considered to be a *jTEI* document when the root element is named *TEI*, it is in the namespace *http://www.tei-c.org/ns/1.0*, and the `@rend` attribute is set to *"jTEI"*.

Default Document Templates

There is a default **jTEI Article** template available when creating *new documents from templates* and they can be found in: **Framework Templates** > **TEI JTEI**.

The default template is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/templates/TEI jTEI` folder.

Default Schema for Validation and Content Completion

The default schema that is used if one is not detected is `tei_jtei.rng` and it is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/custom/schema/relaxng/`.

Default CSS

The default CSS file (`jtei.css`) that is used for rendering jTEI in **Author** mode is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalogs

The default *XML Catalogs* for jTEI are as follows:

- *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/schema/dtd/catalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/custom/schema/dtd/catalog.xml`
- *[OXYGEN_INSTALL_DIR]*`/frameworks/tei/xml/tei/stylesheet/catalog.xml`

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform jTEI documents to PDF and ODT. They can be found in the **TEI JTEI** section in the ***Configure Transformation Scenario(s)** dialog box*.

Adding Tables in TEI Documents on page 615

JATS Document Type (Framework)

The *JATS (NISO Journal Article Tag Suite)* document type is a technical standard that defines an XML format for scientific literature.

File Definition

A file is considered to be a JATS document when the PUBLIC ID of the document contains the string `-//NLM//DTD`.

Default Document Templates

There are some default *JATS* templates available when creating *new documents from templates* and they can be found in: **Framework Templates** > **JATSKit - NISO JATS and NLM BITS**

The default templates for JATS documents are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/jats/templates/` folder.

Default Schema for Validation and Content Completion

Default schemas that are used if one is not detected in the JATS document are stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/jats/lib/schemas/`.

Default CSS

The default CSS files used for rendering JATS content in **Author** mode are stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/jats/lib/author-css/`.

By default, these default CSS files are merged with any that are specified in the document. For more information, see *Configuring and Managing Multiple CSS Styles* on page 1473.

Default XML Catalog

The default *XML Catalog*, `jatskit-catalog.xml`, is stored in *[OXYGEN_INSTALL_DIR]*`/frameworks/jats/lib/schemas/`.

Transformation Scenarios

Oxygen XML Editor includes built-in transformation scenarios that allow you to transform JATS documents to a variety of outputs, such as PDF, HTML, and EPUB. They can be found in the **JATSKit** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

JATS Author Mode Actions

A variety of actions are available in the JATS *framework* that can be added to the **JATS** menu, the **Author Custom Actions** toolbar, the contextual menu, and the *Content Completion Assistant*.

JATS Toolbar Actions

The following default actions are readily available on the **JATS (Author Custom Actions)** toolbar when editing in **Author** mode (by default, they are also available in the **JATS** menu and in various submenus of the contextual menu):

Paragraph Level Drop-Down Menu

Insert Paragraph
Insert a new paragraph element at current cursor position.

Insert Unordered List
Inserts an unordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an unordered list.

Insert Ordered List
Inserts an ordered list at the cursor position. A child list item is also automatically inserted by default. You can also use this action to convert selected paragraphs or other types of lists to an ordered list.

Boxed Text
Inserts or wraps content in a box with a shaded background.

Code
Inserts or wraps content in a `code` element.

Display Quote
Inserts or wraps content in a `disp-quote` element.

Figure
Inserts a `fig` element with a `title` (inside a `caption` element). This action opens a dialog box that allows you to enter the text for the title for the figure.

Graphic Figure
Inserts a `fig` element with a `title` (inside a `caption` element), and a `graphic` element. A dialog box is displayed that allows you to enter the title for the figure, followed by a dialog box that allows you to select the URL of the graphic to be inserted.

Bold

Surrounds the selected text with a `bold` tag. You can use this action on multiple non-contiguous selections.

Italic

Surrounds the selected text with an `italic` tag. You can use this action on multiple non-contiguous selections.

Underline

Surrounds the selected text with an `underline` tag. You can use this action on multiple non-contiguous selections.

Monospace

Inserts or wraps content with a `monospace` element.

Insert Image

Inserts an image reference at the cursor position. Depending on the current location, an image-type element is inserted.

Insert List Item

Inserts a list item in the current list type.

Insert MathML

Opens the **XML Fragment Editor** that allows you to insert and *edit MathML notations*.

Subscript

Surrounds the selected text with a `sub` tag. The text will appear lower than the baseline and slightly smaller.

Superscript

Surrounds the selected text with a `sup` tag. The text will appear higher than the baseline and slightly smaller.

JATS Menu Actions

In addition, the following default actions are available in the **JATS** menu when editing in **Author** mode:

Refresh References

You can use this action to manually trigger a refresh and update of all referenced resources.

Tags display mode Submenu

Full Tags with Attributes

Displays full tag names with attributes for both *block* and *inline elements*.

Full Tags

Displays full tag names without attributes for both *block* and *inline elements*.

Block Tags

Displays full tag names for *block elements* and simple tags without names for *inline elements*.

Inline Tags

Displays full tag names for *inline elements*, while *block elements* are not displayed.

Partial Tags

Displays simple tags without names for *inline elements*, while *block elements* are not displayed.

No Tags

No tags are displayed. This is the most compact mode and is as close as possible to a word-processor view.

Configure Tags Display Mode

Use this option to go to the ***Author*** *preferences page* where you can configure the **Tags Display Mode** options.

Profiling/Conditional Text Submenu

Edit Profiling Attributes

Allows you to configure the *profiling attributes* and their values.

Show Profiling Colors and Styles

Select this option to turn on conditional styling.

Show Profiling Attributes

Select this option to turn on conditional text markers. They are displayed at the end of conditional text blocks, as a list of attribute name and their currently set values.

Show Excluded Content

When this option is selected, the content filtered by the currently applied condition set is grayed-out. To show only the content that matches the currently applied condition set, deselect this option.

List of all profiling condition sets that match the current document type

You can click a listed *condition set* to activate it.

Profiling Settings

Opens the *profiling options preferences page*, where you can manage profiling attributes and profiling conditions sets. You can also configure the profiling styles and colors options from the *colors/styles preferences page* and the *attributes rendering preferences page*.

JATS Drag/Drop Actions

Dragging a file from the ***Project*** *view* or ***DITA Maps Manager*** *view* and dropping it into a JATS document that is edited in **Author** mode, creates a link to the dragged file (the `ext-link` element with the `xlink:href` attribute) at the drop location. Dragging an image file from the default file system application (Windows Explorer on Windows or Finder on Mac OS X, for example) and dropping it into a JATS document inserts an image element (the `inline-graphic` element with the `xlink:href` attribute) at the drop location, similar to the **Insert Image** toolbar action.

EPUB Document Type (Framework)

EPUB is an e-book file format that is a ZIP archive and can be downloaded and read on devices such as phones, tablets, computers, or e-readers. Oxygen XML Editor includes an ***Archive Browser*** *view* that allows you to view the contents and structure of this type of file.

Three distinct *frameworks* are supported for the EPUB document type:

- **NCX** - A declarative global navigation definition.
- **OCF** - The Open Container Format (OCF) defines a mechanism by which all components of an Open Publication Structure (OPS) can be combined into a single file system entity.
- **OPF** - The Open Packaging Format (OPF) defines the mechanism by which all components of a published work that conforms to the Open Publication Structure (OPS) standard (including metadata, reading order, and navigational information) are packaged in an OPS Publication.

  Note: Oxygen XML Editor supports OPF 2.0, OPF 3.0, and OPF 3.1.

File Definition

A file is considered to be an *EPUB* document if it has a file extension of `.epub`.

Default Document Templates

There are a variety of default *EPUB* templates available when creating *new documents from templates* and they can be found the following folders in **Framework Templates**: **NCX**, **OCF**, **OPF 2.0**, **OPF 3.0**, and **OPF 3.1**.

- The default templates for the **NCX** document types are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/ncx/templates` folder.
- The default templates for the **OCF** document types are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/ocf/templates` folder.

- The default template for the **OPF 2.0** document type is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/opf/templates/2.0` folder.
- The default template for the **OPF 3.0** document type is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/opf/templates/3.0` folder.
- The default template for the **OPF 3.1** document type is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/opf/templates/3.1` folder.

Default Schema

The default schema files for the various types of EPUB document types are located in the following directories:

- The default schema files for the **NCX** document types are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/ncx/schemas` folder.
- The default schema files for the **OCF** document types are located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/ocf/schemas` folder.
- The default schema files for the **OPF 2.0** document type is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/opf/schemas/2.0` folder.
- The default schema files for the **OPF 3.0** document type is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/opf/schemas/3.0` folder.
- The default schema files for the **OPF 3.1** document type is located in the *[OXYGEN_INSTALL_DIR]*`/frameworks/opf/schemas/3.1` folder.

Related Information:

Working with Archive Files on page 1280

Other Supported Document Types

Along with the *fully supported predefined frameworks (document types)*, Oxygen XML Editor also provides limited support (including file templates) for editing a variety of other document types. All the specialized views, editors, actions, and options are dynamic according to the type of file that is opened or created. Other document types that are supported in Oxygen XML Editor include:

- *EPUB (NCX, OCF, OPF 2.0, 3.0, & 3.1)* - A standard for e-book files.
- *OOXML* - An XML-based file format for representing spreadsheets, charts, presentations, and word processing documents.
- *ODF* - An free and open-source XML-based file format for electronic office documents, such as spreadsheets, charts, presentations, and word processing documents.
- *DocBook Targetset* - For resolving cross-references when using *olinks*.
- *Ant Build Scripts* - A tool for automating software build processes, written in Java and primarily intended for use with Java.
- *XSLT Stylesheets* - A document type that provides a visual mode for editing XSLT stylesheets.
- *WSDL* - Web Services Description Language is an XML language for describing the functionality offered by a web service.
- *Schematron* - For making assertions about the presence or absence of patterns in XML documents. This document type applies to the ISO Schematron version.
- *Schematron Quick Fixes (SQF)* - An extension of the ISO standard Schematron, allows developers to define *Quick Fixes* for Schematron errors.
- *StratML (Part 1 & 2)* - Part 1 and 2 of the Strategy Markup Language specification.
- *XProc* - A document type for processing XProc script files.
- *XML Schema* - Documents that provide support for editing annotations.
- *SVG* - Scalable Vector Graphics is a language for describing two-dimensional graphics in XML.
- *MathML* - Mathematical Markup Language (2.0 and 3.0) is an application of XML for describing mathematical notations.
- *XLIFF (1.2 & 2.0)* - XML Localization Interchange File Format is a standard for passing data between tools during a localization process.
- *XQuery* - The common query language for XML.

- *CSS* - Cascading Style Sheets is a language used for describing the look and formatting of a document.
- *LESS* - A dynamic style sheet language that can be compiled into CSS.
- *Relax NG Schema* - A schema language that specifies a pattern for the structure and content of an XML document.
- *NVDL Schema* - Namespace Validation Dispatching Language allows you to specify sections of XML documents to be validated against various schemas.
- *JSON* - JavaScript Object Notation is a lightweight data-interchange format.
- *Markdown* - A lightweight markup language with plain text formatting syntax that can be converted to HTML or DITA.
- *JavaScript* - Programming language of HTML and the Web.
- XMLSpec - A markup language for W3C specifications and other technical reports.
- DITAVAL - DITA conditional processing profile to identify the values you want to conditionally process for a particular output, build, or other purpose.
- Daisy - A technical standard for digital audio books, periodicals, and computerized text. It is designed to be an audio substitute for print material.
- EAD - Encoded Archival Description is an XML standard for encoding archival finding aids.
- KML - Keyhole Markup Language is an XML notation for expressing geographic visualization in maps and browsers.
- Maven Project & Settings - Project or settings file for Maven build automation tool that is primarily used for Java projects.
- Oasis *XML Catalog* - An *XML Catalog* document that describes a mapping between external entity references and locally-cached equivalents.
- *Other Non-XML Files*- Oxygen XML Editor also includes a simple text editor and a variety of helpful features for creating and editing non-XML files.

Transforming Documents

9

Topics:

- *Transformation Scenarios*
- *WebHelp System Output*

XML documents can be transformed into a variety of user-friendly output formats that can be viewed by other users. This process is known as a *transformation*.

Oxygen XML Editor allows you to use transformation scenarios to publish XML content in various output formats (such as WebHelp, PDF, CHM, EPUB, JavaHelp, Eclipse Help, XHTML, etc.)

For transformations that are not included in your installed version of Oxygen XML Editor, simply install the tool chain required to perform the specific transformation and process the files in accordance with the processor instructions. A multitude of target formats are possible. The basic condition for transformation to any format is that your source document is well-formed.

Note: You need to use the appropriate stylesheet according to the source definition and the desired output. For example, if you want to transform into an HTML format using a DocBook stylesheet, your source XML document should conform with the DocBook DTD.

Transformation Scenarios

A transformation scenario is a set of complex operations and settings that gives you the possibility to obtain outputs of multiple types (XML, HTML, PDF, EPUB, etc.) from the same source of XML files and stylesheets.

Executing a transformation scenario implies multiple actions, such as:

- Validating the input file.
- Obtaining intermediate output files (for example, formatting objects for the XML to PDF transformation).
- Using transformation engines to produce the output.

Before transforming an XML document in Oxygen XML Editor, you need to define a transformation scenario to apply to that document. A scenario is a set of values for various parameters that define a transformation. It is not related to a particular document, but rather to a document type. Types of transformation scenarios include:

- **Scenarios that Apply to XML Files** - This type of scenario contains the location of an XSLT stylesheet that is applied on the edited XML document, as well as other transformation parameters.
- **Scenarios that Apply to XSLT Files** - This type of scenario contains the location of an XML document that the edited XSLT stylesheet is applied to, as well as other transform parameters.
- **Scenarios that Apply to XQuery Files** - This type of scenario contains the location of an XML source, that the edited XQuery file is applied to, as well as other transform parameters. When the XML source is a native XML database, the XML source field of the scenario is empty because the XML data is read with XQuery-specific functions, such as `document()`. When the XML source is a local XML file, the URL of the file is specified in the XML input field of the scenario.
- **Scenarios that Apply to SQL Files** - This type of scenario specifies a database connection for the database server that runs the SQL file that is associated with the scenario. The data processed by the SQL script is located in the database.
- **Scenarios that Apply to XProc Files** - This type of scenario contains the location of an XProc script, as well as other transform parameters.
- **DITA-OT Scenarios** - This type of scenario provides the parameters for an Ant transformation that executes a DITA-OT build script. Oxygen XML Editor includes a built-in version of Ant and a built-in version of DITA-OT, although you can also set other versions in the scenario.

- **ANT Scenarios** - This type of scenario contains the location of an Ant build script, as well as other transform parameters.

Note:

Status messages generated during the transformation process are displayed in the ***Information*** *view*.

Built-in Transformation Scenarios

Oxygen XML Editor included preconfigured built-in transformation scenarios that are used for common transformations. They can be found in the various sections in the ***Configure Transformation Scenario(s)*** *dialog box* or ***Transformation Scenarios*** *view*. All the predefined *document types (frameworks)* that are included in Oxygen XML Editor have various transformation scenarios in their specific sections, including the most popular *frameworks*, such as DITA, DocBook, TEI, XHTML, JATS, OOXML, and more.

To obtain the desired output, use one of the following actions from the toolbar or **Transform** submenu in the contextual menu of the ***Project*** *view*:

- **Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))** - If you have associated transformation scenarios for the current document, this action will simply *apply the association* and begin the transformation process. If an association is not detected, this action will open the ***Configure Transformation Scenario(s)*** *dialog box* where you can choose the scenarios you want to apply.
- **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** - This action will open the ***Configure Transformation Scenario(s)*** *dialog box* where you can choose the scenarios you want to apply.

Note:

- You can apply a transformation even if the current document is not associated with a transformation scenario.
- If the document contains an `xml-stylesheet` processing instruction that refers to an XSLT stylesheet (commonly used to display the document in web browsers), Oxygen XML Editor prompts you to associate the document with a built-in transformation scenario.
- The default transformation scenario is suggested based on the processing instruction from the edited document.

DocBook 4 Transformation Scenarios

Default transformation scenarios allow you to convert DocBook 4 to DocBook 5 documents and transform DocBook documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. All of them are listed in the **DocBook 4** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

DocBook 4 to WebHelp Output

DocBook 4 documents can be transformed into several types of WebHelp systems.

WebHelp Classic Output

To publish a DocBook 4 document as a **WebHelp Classic** system, follow these steps:

1. Click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
2. Select the **DocBook WebHelp Classic** scenario from the **DocBook 4** section.
3. Click **Apply associated**.

   When the **DocBook WebHelp Classic** transformation is complete, the output is automatically opened in your default browser.

WebHelp Classic with Feedback Output

To publish a DocBook 4 document as a **WebHelp Classic with Feedback** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic with Feedback** scenario from the **DocBook 4** section.
3. Click **Apply associated**.
4. Enter the documentation product ID and the documentation version.

   When the **DocBook WebHelp Classic with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment. For more information, see *Deploying a Feedback-Enabled WebHelp System*.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

WebHelp Classic Mobile Output

To publish a DocBook 4 document as a **WebHelp Classic Mobile** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic Mobile** scenario from the **DocBook 4** section.
3. Click **Apply associated**.

When the **DocBook WebHelp Classic Mobile** transformation is complete, the output is automatically opened in your default browser.

Customizing WebHelp Transformation Scenarios

To customize a DocBook WebHelp transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

l10n.gentext.default.language

This parameter is used to identify the correct stemmer that differs from language to language. For example, for English the value of this parameter is `en` or for French it is `fr`, and so on.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, `mobile-phone-user-guide`, `hvac-installation-guide`).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.skin.css

Path to a CSS file that sets the style theme in the output WebHelp pages. It can be one of the predefined skin CSS from the `OXYGEN_INSTALL_DIR\frameworks\docbook\xsl\com.oxygenxml.webhelp`

`\predefined-skins` directory, or it can be a custom skin CSS generated with the *Oxygen Skin Builder* web application.

For more information about all the DocBook transformation parameters, go to *http://docbook.sourceforge.net/release/xsl/current/doc/fo/index.html*.

Customizing WebHelp Classic Mobile Systems on page 1239

DocBook to PDF Output Customization

When the default layout and output of the DocBook to PDF transformation needs to be customized, follow these steps:

1. Create a custom version of the DocBook title spec file.

   You should start from a copy of the file *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/fo/titlepage.templates.xml` and customize it. The instructions for the spec file can be found *here.*

   An example of spec file:

   ```
   <t:titlepage-content t:side="recto">
       <mediaobject/>
       <title
           t:named-template="book.verso.title"
           font-size="&hsize2;"
           font-weight="bold"
           font-family="{$title.font.family}"/>
       <corpauthor/>
         ...
   </t:titlepage-content>
   ```

2. Generate a new XSLT stylesheet from the title spec file from the previous step.

   Apply *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/template/titlepage.xsl` to the title spec file. The result is an XSLT stylesheet (for example, `mytitlepages.xsl`).

3. Import `mytitlepages.xsl` in a *DocBook customization layer*.

   The customization layer is the stylesheet that will be applied to the XML document. The `mytitlepages.xsl` should be imported with an element like this:

   ```
   <xsl:import href="dir-name/mytitlepages.xsl"/>
   ```

4. Insert a logo image in the XML document.

   The path to the logo image must be inserted in the `book/info/mediaobject` element of the XML document.

5. Apply the customization layer to the XML document.

   A quick way is to duplicate the transformation scenario **DocBook PDF** that is included with Oxygen XML Editor and set the customization layer in *the **XSL URL** property of the scenario*.

Related Information:

*The book **DocBook XSL: The Complete Guide** by Bob Stayton contains more details about customizing the PDF output.*
Video demonstration for creating a DocBook customization layer in Oxygen XML Editor.

DocBook to DITA Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to DITA. This transformation scenario is based upon a DITA Open Toolkit plugin that is available at *sourceforge.net*.

To convert a DocBook document to DITA, follow these steps:

1. Use one of the following two methods to begin the transformation process:

- To apply the transformation scenario to a newly opened file, use the **Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
- To customize the transformation or change the scenario that is associated with the document, use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.

2. Select the **DocBook to DITA** transformation scenario in the **DocBook 4** or **DocBook 5** section.
3. Click the **Apply associated** button to run the transformation.

   Step Result: The transformation will convert as many of the DocBook elements into equivalent DITA elements as it can recognize in its mapping process. For elements that cannot be mapped, the transformation will insert XML comments so that you can see which elements could not be converted.
4. Adjust the resulting DITA composite to suit your needs. You may have to remove comments, fix validation errors, adjust certain attributes, or split the content into individual topics.

Related Information:

Editing a Transformation Scenario on page 1136
Configure Transformation Scenario(s) Dialog Box on page 1138

DocBook to EPUB Transformation

The EPUB specification recommends the use of *OpenType* fonts (recognized by their `.otf` file extension) when possible. To use a specific font, follow these steps:

1. Declare it in your CSS file, as in the following example:

```
@font-face {
font-family: "MyFont";
font-weight: bold;
font-style: normal;
src: url(fonts/MyFont.otf);
}
```

2. In the CSS, specify where this font is used. To set it as default for h1 elements, use the `font-family` rule, as in the following example:

```
h1 {
font-size:20pt;
margin-bottom:20px;
font-weight: bold;
font-family: "MyFont";
text-align: center;
}
```

3. Open the ***Configure Transformation Scenario(s)*** *dialog box*, select the **DocBook EPUB** transformation scenario, and click **Edit**.
4. In the **Parameters** tab, set the `epub.embedded.fonts` parameter to `fonts/MyFont.otf`. If you need to provide more files, use commas to separate their file paths.

   Note: The `html.stylesheet` parameter allows you to include a custom CSS in the output EPUB.
5. Run the transformation scenario.

DocBook 5 Transformation Scenarios

Built-in transformation scenarios allow you to transform DocBook 5 documents to a variety of outputs, such as WebHelp, PDF, HTML, HTML Chunk, XHTML, XHTML Chunk, and EPUB. Oxygen XML Editor also includes a DocBook 5.1 transformation scenario for *Assembly* documents. All of them are listed in the **DocBook 5** section in the ***Configure Transformation Scenario(s)*** *dialog box*.

Related Information:

Editing a Transformation Scenario on page 1136
Configure Transformation Scenario(s) Dialog Box on page 1138
Apply Associated Transformation Scenarios on page 1141

DocBook 5 to WebHelp Output

DocBook 5 documents can be transformed into several types of WebHelp systems.

WebHelp Classic Output

To publish a DocBook 5 document as a **WebHelp Classic** system, follow these steps:

1. Click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
2. Select the **DocBook WebHelp Classic** scenario from the **DocBook 5** section.
3. Click **Apply associated**.

   When the **DocBook WebHelp Classic** transformation is complete, the output is automatically opened in your default browser.

WebHelp Classic with Feedback Output

To publish a DocBook 5 document as a **WebHelp Classic with Feedback** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic with Feedback** scenario from the **DocBook 5** section.
3. Click **Apply associated**.
4. Enter the documentation product ID and the documentation version.

   When the **DocBook WebHelp Classic with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the instructions to complete the system deployment. For more information, see *Deploying a Feedback-Enabled WebHelp System*.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

WebHelp Classic Mobile Output

To publish a DocBook 5 document as a **WebHelp Classic Mobile** system, follow these steps:

1. Click **Configure Transformation Scenarios**.
2. Select the **DocBook WebHelp Classic Mobile** scenario from the **DocBook 5** section.
3. Click **Apply associated**.

When the **DocBook WebHelp Classic Mobile** transformation is complete, the output is automatically opened in your default browser.

Customizing WebHelp Transformation Scenarios

To customize a DocBook WebHelp transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

l10n.gentext.default.language

This parameter is used to identify the correct stemmer that differs from language to language. For example, for English the value of this parameter is `en` or for French it is `fr`, and so on.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, `mobile-phone-user-guide`, `hvac-installation-guide`).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.skin.css

Path to a CSS file that sets the style theme in the output WebHelp pages. It can be one of the predefined skin CSS from the `OXYGEN_INSTALL_DIR\frameworks\docbook\xsl\com.oxygenxml.webhelp\predefined-skins` directory, or it can be a custom skin CSS generated with the *Oxygen Skin Builder* web application.

For more information about all the DocBook transformation parameters, go to *http://docbook.sourceforge.net/release/xsl/current/doc/fo/index.html*.

DocBook to PDF Output Customization

When the default layout and output of the DocBook to PDF transformation needs to be customized, follow these steps:

1. Create a custom version of the DocBook title spec file.

   You should start from a copy of the file *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/fo/titlepage.templates.xml` and customize it. The instructions for the spec file can be found *here*.

   An example of spec file:

   ```
   <t:titlepage-content t:side="recto">
       <mediaobject/>
       <title
           t:named-template="book.verso.title"
           font-size="&hsize2;"
           font-weight="bold"
           font-family="{$title.font.family}"/>
       <corpauthor/>
         ...
   </t:titlepage-content>
   ```

2. Generate a new XSLT stylesheet from the title spec file from the previous step.

   Apply *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/template/titlepage.xsl` to the title spec file. The result is an XSLT stylesheet (for example, `mytitlepages.xsl`).

3. Import `mytitlepages.xsl` in a *DocBook customization layer*.

   The customization layer is the stylesheet that will be applied to the XML document. The `mytitlepages.xsl` should be imported with an element like this:

   ```
   <xsl:import href="dir-name/mytitlepages.xsl"/>
   ```

4. Insert a logo image in the XML document.

   The path to the logo image must be inserted in the `book/info/mediaobject` element of the XML document.

5. Apply the customization layer to the XML document.

   A quick way is to duplicate the transformation scenario **DocBook PDF** that is included with Oxygen XML Editor and set the customization layer in *the **XSL URL** property of the scenario*.

Related Information:

*The book **DocBook XSL: The Complete Guide** by Bob Stayton contains more details about customizing the PDF output.*
Video demonstration for creating a DocBook customization layer in Oxygen XML Editor.

Show Comments and Tracked Changes in DocBook 5 PDF Output

To include comments and *tracked changes* (stored within your DocBook 5 documents) in the PDF output, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button.
2. Select **DocBook PDF (Show Change Tracking and Comments)** in the **DocBook 5** section.
3. If you need to configure the transformation, click the ***Edit*** or ***Duplicate*** button, make your changes to the scenario, and click **OK**.
4. Click the **Apply Associated** button to run the transformation scenario.

   Result: Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

DocBook to DITA Transformation

Oxygen XML Editor includes a built-in transformation scenario that is designed to convert DocBook content to DITA. This transformation scenario is based upon a DITA Open Toolkit plugin that is available at *sourceforge.net*.

To convert a DocBook document to DITA, follow these steps:

1. Use one of the following two methods to begin the transformation process:
   - To apply the transformation scenario to a newly opened file, use the **Apply Transformation Scenario(s) (Ctrl + Shift + T (Command + Shift + T on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
   - To customize the transformation or change the scenario that is associated with the document, use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
2. Select the **DocBook to DITA** transformation scenario in the **DocBook 4** or **DocBook 5** section.
3. Click the **Apply associated** button to run the transformation.

   Step Result: The transformation will convert as many of the DocBook elements into equivalent DITA elements as it can recognize in its mapping process. For elements that cannot be mapped, the transformation will insert XML comments so that you can see which elements could not be converted.
4. Adjust the resulting DITA composite to suit your needs. You may have to remove comments, fix validation errors, adjust certain attributes, or split the content into individual topics.

Related Information:

Editing a Transformation Scenario on page 1136
Configure Transformation Scenario(s) Dialog Box on page 1138

DocBook to EPUB Transformation

The EPUB specification recommends the use of *OpenType* fonts (recognized by their `.otf` file extension) when possible. To use a specific font, follow these steps:

1. Declare it in your CSS file, as in the following example:

```
@font-face {
font-family: "MyFont";
font-weight: bold;
font-style: normal;
src: url(fonts/MyFont.otf);
}
```

2. In the CSS, specify where this font is used. To set it as default for `h1` elements, use the `font-family` rule, as in the following example:

```
h1 {
font-size:20pt;
margin-bottom:20px;
font-weight: bold;
font-family: "MyFont";
text-align: center;
}
```

3. Open the ***Configure Transformation Scenario(s)*** *dialog box*, select the **DocBook EPUB** transformation scenario, and click **Edit**.
4. In the **Parameters** tab, set the `epub.embedded.fonts` parameter to `fonts/MyFont.otf`. If you need to provide more files, use commas to separate their file paths.

   Note: The `html.stylesheet` parameter allows you to include a custom CSS in the output EPUB.
5. Run the transformation scenario.

DITA Map Transformation Scenarios

The following types of transformations scenarios are available for *DITA maps*:

- Predefined transformation scenarios allow you to transform a *DITA map* to a variety of outputs, such as WebHelp, PDF, ODF, XHTML, EPUB, CHM, Kindle, and MS Word.
- **Run DITA-OT Integrator** - Use this transformation scenario if you want to *integrate a DITA-OT plugin*. This scenario runs an Ant task that integrates all the plugins from the DITA-OT/plugins directory.
- **DITA Map Metrics Report** - Use this type of transformation scenario if you want to generate a *DITA map* statistics report. They contain information such as:
  - The number of processed maps and topics.
  - Content reuse percentage.
  - Number of elements, attributes, words, and characters used in the entire *DITA map* structure.
  - DITA conditional processing attributes used in the *DITA maps*.
  - Words count.
  - Information types such as number of containing *maps*, *bookmaps*, or topics.

DITA Map to WebHelp Output

DITA maps can be transformed into a variety of WebHelp systems designed to suit your specific needs. This section contains the procedures for obtaining the output for the variants of the WebHelp system.

Related Information:

WebHelp System Output on page 1152

WebHelp Responsive Output

To publish a *DITA map* as a **WebHelp Responsive** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Responsive** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Templates Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.
   - *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
   - *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
   - *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
   - *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.
4. Click **Apply associated** to process the transformation.

When the **DITA Map WebHelp Responsive** transformation is complete, the output is automatically opened in your default browser.

Parameters for Customizing WebHelp Responsive Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

editlink.remote.ditamap.url

Use this parameter in conjunction with `editlink.web.author.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the *main DITA map*. For example, a GitHub custom URL might look like this: `https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap`.

editlink.web.author.url

This parameter needs to be used in conjunction with `editlink.remote.ditamap.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the URL of the Web Author installation. For example: `https://www.oxygenxml.com/webapp-demo-aws/app/oxygen.html`.

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.enable.pagination

Specifies whether or not search results will be displayed on multiple pages. Allowed values are `yes` or `no`.

webhelp.search.page.numberOfItems

Specifies the number of search results items displayed on each page. This parameter is only used when the **webhelp.search.enable.pagination** parameter is enabled.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is `no`.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

Parameters Specific to WebHelp Responsive Output

webhelp.default.collection.type

Specifies if the **sequence** value will be used by default when the `collection-type` attribute is not specified. This option is helpful if you want to have *Next* and *Previous* navigational buttons generated for all HTML pages. Allowed values are **no** (default) and **yes**.

webhelp.enable.search.autocomplete

Specifies if the *Autocomplete* feature is enabled in the WebHelp search text field. The default value is `yes`.

webhelp.fragment.after.body

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.logo_and_title

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.main.page.search

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.toc_or_tiles

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.top_menu

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.logo_and_title

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.page.search

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.toc_or_tiles

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.top_menu

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.head

In the generated output it inserts a given XHTML fragment in the <head> element. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.welcome

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, *Related Tasks*, *Related References*, *Related Information*) are merged into a single group. The default value is yes.

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is yes.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.

webhelp.show.indexterms.link

Specifies if an icon that links to the index will be presented in the output. The default value is yes.

webhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a *tree* style layout, this parameter should be set to no.

webhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is yes.

webhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is yes.

webhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is yes.

webhelp.show.related.links

Specifies if the related links component will be presented in the WebHelp Responsive output. The default value is `yes`. The webhelp.merge.nested.topics.related.links parameter can used in conjunction with this one to merge the related links from nested topics into the links in the parent topic.

webhelp.show.side.toc

Specifies if a side table of contents will be presented on the right side of each topic in the output. The default value is `yes`.

webhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is `yes`.

webhelp.side.toc.links

Specifies which links will be included in the side table of contents. The possible values are:

- **chapter** (default) - The side TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The side TOC will only include links for the current topic and its direct children.
- **all** - The side TOC will include all links.

webhelp.side.toc.tooltip.position

By default, if a topic contains a `shortdesc` element, its content is displayed in a tooltip when the user hovers over its link in the side table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 2.

WebHelp Responsive System on page 1153

WebHelp Responsive with Feedback Output

To publish a *DITA map* as a **WebHelp Responsive with Feedback** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Responsive with Feedback** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Templates Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.
   - *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
   - *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
   - *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
   - *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.
4. Click **Apply associated** to begin the transformation.
5. Enter the documentation product ID (value for the `webhelp.product.id` parameter) and the documentation version (value for the `webhelp.product.version` parameter).

When the **DITA Map WebHelp Responsive with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the *instructions to complete the system deployment*.

Parameters for Customizing WebHelp Responsive with Feedback Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

editlink.remote.ditamap.url

Use this parameter in conjunction with `editlink.web.author.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the custom URL of the *main DITA map*. For example, a GitHub custom URL might look like this: `https://getFileContent/oxyengxml/userguide/master/UserGuide.ditamap`.

editlink.web.author.url

This parameter needs to be used in conjunction with `editlink.remote.ditamap.url` to add an *Edit* link next to the topic title in the WebHelp output. When a user clicks the link, the topic is opened in Oxygen XML Web Author where they can make changes that can be saved to a file server. The value should be set as the URL of the Web Author installation. For example: `https://www.oxygenxml.com/webapp-demo-aws/app/oxygen.html`.

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.enable.pagination

Specifies whether or not search results will be displayed on multiple pages. Allowed values are `yes` or `no`.

webhelp.search.page.numberOfItems

Specifies the number of search results items displayed on each page. This parameter is only used when the **webhelp.search.enable.pagination** parameter is enabled.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is `no`.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

Parameters Specific to WebHelp Responsive with Feedback Output

webhelp.default.collection.type

Specifies if the **sequence** value will be used by default when the `collection-type` attribute is not specified. This option is helpful if you want to have *Next* and *Previous* navigational buttons generated for all HTML pages. Allowed values are **no** (default) and **yes**.

webhelp.enable.search.autocomplete

Specifies if the *Autocomplete* feature is enabled in the WebHelp search text field. The default value is `yes`.

webhelp.fragment.after.body

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.logo_and_title

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.main.page.search

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.toc_or_tiles

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.after.top_menu

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.body

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.logo_and_title

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.main.page.search

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.toc_or_tiles

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.before.top_menu

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.head

In the generated output it inserts a given XHTML fragment in the <head> element. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.fragment.welcome

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

webhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, *Related Tasks*, *Related References*, *Related Information*) are merged into a single group. The default value is yes.

webhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is yes.

webhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.

webhelp.show.indexterms.link

Specifies if an icon that links to the index will be presented in the output. The default value is yes.

webhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a *tree* style layout, this parameter should be set to no.

webhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is yes.

webhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is yes.

webhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is yes.

webhelp.show.related.links

Specifies if the related links component will be presented in the WebHelp Responsive output. The default value is `yes`. The webhelp.merge.nested.topics.related.links parameter can used in conjunction with this one to merge the related links from nested topics into the links in the parent topic.

webhelp.show.side.toc

Specifies if a side table of contents will be presented on the right side of each topic in the output. The default value is `yes`.

webhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is `yes`.

webhelp.side.toc.links

Specifies which links will be included in the side table of contents. The possible values are:

- **chapter** (default) - The side TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The side TOC will only include links for the current topic and its direct children.
- **all** - The side TOC will include all links.

webhelp.side.toc.tooltip.position

By default, if a topic contains a `shortdesc` element, its content is displayed in a tooltip when the user hovers over its link in the side table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

webhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 2.

WebHelp Classic Output

To publish a *DITA map* as a **WebHelp Classic** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Classic** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Skins Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.
   - *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
   - *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
   - *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
   - *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.
4. Click **Apply associated** to process the transformation.

   When the **DITA Map WebHelp Classic** transformation is complete, the output is automatically opened in your default browser.

To further customize this transformation, you can edit various parameters, including the following most commonly used ones:

Parameters for Customizing WebHelp Classic Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only no and `yes` values are valid and the default value is no).

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.body.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<body>` section of every WebHelp page.

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value,

then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.google.search.results

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (*iframe*) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

webhelp.google.search.script

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

webhelp.head.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<head>` section of every WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8.

The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

WebHelp Classic With Feedback Output

To publish a *DITA map* as a **WebHelp Classic with Feedback** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Classic with Feedback** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Skins Tab* - This tab contains a set of predefined skins that you can use for the layout of your WebHelp system output.
   - *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
   - *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
   - *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
   - *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.
4. Click **Apply associated** to begin the transformation.
5. Enter the documentation product ID (value for the `webhelp.product.id` parameter) and the documentation version (value for the `webhelp.product.version` parameter).

   When the **DITA Map WebHelp Classic with Feedback** transformation is complete, your default browser opens the `installation.html` file. This file contains information about the output location, system requirements, installation instructions, and deployment of the output. Follow the *instructions to complete the system deployment*.

For more information about the feedback-enabled WebHelp system, watch our video demonstration:

Parameters for Customizing WebHelp Classic with Feedback Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only `no` and `yes` values are valid and the default value is `no`).

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.body.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<body>` section of every WebHelp page.

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.google.search.results

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (*iframe*) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

webhelp.google.search.script

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

webhelp.head.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<head>` section of every WebHelp page.

webhelp.logo.image.target.url

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

webhelp.logo.image

Specifies a path to an image displayed as a logo in the left side of the output header.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.search.ranking

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

webhelp.show.changes.and.comments

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

WebHelp Classic Mobile Output

To publish a *DITA map* as a **WebHelp Classic Mobile** system, follow these steps:

1. Select the **Configure Transformation Scenario(s)** action from the ***DITA Maps Manager*** toolbar.
2. Select the **DITA Map WebHelp Classic Mobile** scenario from the **DITA Map** section.
3. If you want to configure the transformation, click the **Edit** button.

   Step Result: This opens an **Edit scenario** configuration dialog box that allows you to configure various options in the following tabs:

   - *Parameters Tab* - This tab includes numerous parameters that can be set to customize your WebHelp system output. See the *Parameters section* below for details about the most commonly used parameters for WebHelp Responsive transformations.
   - *Filters Tab* - This tab allows you to filter certain content elements from the generated output.
   - *Advanced Tab* - This tab allows you to specify some advanced options for the transformation scenario.
   - *Output Tab* - This tab allows you to configure options that are related to the location where the output is generated.

4. Click **Apply associated** to process the transformation.

   When the **DITA Map WebHelp Classic Mobile** transformation is complete, the output is automatically opened in your default browser.

Parameters for Customizing WebHelp Classic Mobile Output

To customize a transformation scenario, you can edit various parameters, including the following most commonly used ones:

args.default.language

This parameter is used if the language is not detected in the *DITA map*. The default value is `en-us`.

clean.output

Deletes all files from the output folder before the transformation is performed (only no and `yes` values are valid and the default value is no).

fix.external.refs.com.oxygenxml (Only supported when the DITA OT transformation process is started from Oxygen XML Editor)

The DITA Open Toolkit usually has problems processing references that point to locations outside of the directory of the processed *DITA map*. This parameter is used to specify whether or not the application should try to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references. The fix has no impact on your edited DITA content. Allowed values: `true` or `false` (default).

force.unique

When set to `true` (default value), the transformation will be forced to create unique output files for each instance of a resource when a map contains multiple references to a single topic.

use.stemming

Controls whether or not you want to include stemming search algorithms into the published output (default setting is `false`).

webhelp.copyright

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

webhelp.custom.resources

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

webhelp.favicon

The file path that points to an image to be used as a *favicon* in the WebHelp output.

webhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

webhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

webhelp.google.search.results

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (*iframe*) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

webhelp.google.search.script

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

webhelp.head.script

URL value that specifies the location of a well-formed XHTML file containing the custom script that will be copied in the `<head>` section of every WebHelp page.

webhelp.reload.stylesheet

Set this parameter to `true` if you have out of memory problems when generating WebHelp. It will increase processing time but decrease the memory footprint. The default value is `false`.

webhelp.search.custom.excludes.file

The path of the file that contains name patterns for HTML files that should not be indexed by the WebHelp search engine. Each exclude pattern must be on a new line. The patterns are considered to be relative to the output directory, and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

webhelp.search.japanese.dictionary

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

webhelp.sitemap.base.url

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

webhelp.sitemap.change.frequency

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

webhelp.sitemap.priority

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

WebHelp Classic Mobile System (Deprecated) on page 1238

DITA Map to PDF Output Customization

Oxygen XML Editor comes bundled with the DITA Open Toolkit that provides a mechanism for converting *DITA maps* to PDF output. There are numerous ways that you can customize the PDF output and the topics in this section discuss some of those possibilities.

Creating a DITA Map to PDF Transformation Scenario

To create a *DITA Map to PDF* transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF** and click the **Edit** button (or use the **Duplicate** button if your *framework* is read-only).
3. Use the various tabs to configure the transformation scenario. In the **Parameters** tab, you can use a variety of parameters to customize the output. For example, the following parameters are just a few of the most commonly used ones:
   - `show.changes.and.comments` - If set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output.
   - `customization.dir` - Specifies the path to a customization directory.
4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.

Customizing the PDF Output

DITA Open Toolkit PDF output can be customized in several ways:

- Creating a DITA Open Toolkit plugin that adds extensions to the PDF plugin. More details can be found in the *DITA Open Toolkit Documentation*.
- Creating a customization directory and using it from the PDF transformation scenario. A small example of this procedure can be found below.

How to Create a Customization Directory for PDF Output

The following procedure explains how to do a basic customization of the PDF output by setting up a customization directory. An example of a common use case is embedding a company logo image in the front matter of the book.

1. Copy the entire directory: *DITA-OT-DIR*`\plugins\org.dita.pdf2\Customization` to another location (for instance, `C:\Customization`).
2. Copy your logo image to: `C:\Customization\common\artwork\logo.png`.
3. Rename `C:\Customization\catalog.xml.orig` to: `C:\Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and *uncomment* this line:

   ```
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->
   ```

   It now looks like this:

   ```
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```
5. Rename the file: `C:\Customization\fo\xsl\custom.xsl.orig` to: `C:\Customization\fo\xsl\custom.xsl`
6. Open the `custom.xsl` file in Oxygen XML Editor and create the template called **createFrontCoverContents** for DITA-OT 2.5.2 (or createFrontMatter_1.0 for DITA-OT 1.8.5).

   Tip: You can copy the same template from *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl` and modify it in whatever way necessary to achieve your specific goal. This new template in the `custom.xsl` file will override the same template from *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\front-matter.xsl`.

   DITA OT 2.5.2 Example:

   For example, if you are using DITA OT 2.5.2, the `custom.xsl` could look like this:

   ```
   <?xml version='1.0'?>
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
       xmlns:fo="http://www.w3.org/1999/XSL/Format"
       version="2.0">

   <xsl:template name="createFrontCoverContents">
    <!-- set the title -->
    <fo:block xsl:use-attribute-sets="__frontmatter__title">
     <xsl:choose>
      <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
       <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
         </xsl:when>
         <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
           <xsl:apply-templates select="$map//*[contains
                                       (@class,' bookmap/mainbooktitle ')][1]"/>
         </xsl:when>
         <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
   ```

```
        <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
      </xsl:when>
      <xsl:otherwise>
        <xsl:value-of select="/descendant::*[contains
           (@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
   </xsl:otherwise>
  </xsl:choose>
 </fo:block>

 <!-- set the subtitle -->
 <xsl:apply-templates select="$map//*[contains
                                    (@class,' bookmap/booktitlealt ')]"/>
 <fo:block xsl:use-attribute-sets="__frontmatter__owner">
  <xsl:apply-templates select="$map//*[contains(@class,' bookmap/bookmeta ')]"/>
 </fo:block>

 <!-- Load the image logo -->
  <fo:block text-align="center" width="100%">
   <fo:external-graphic
      src="url({concat($artworkPrefix,
                       '/Customization/OpenTopic/common/artwork/logo.png')})"
    />
  </fo:block>
 </xsl:template>

</xsl:stylesheet>
```

DITA OT 1.8.5 Example:

For example, if you are using DITA OT 1.8.5, the `custom.xsl` could look like this:

```
<?xml version='1.0'?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:fo="http://www.w3.org/1999/XSL/Format"
    version="1.1">

<xsl:template name="createFrontMatter_1.0">
   <fo:page-sequence master-reference="front-matter"
                        xsl:use-attribute-sets="__force__page__count">
     <xsl:call-template name="insertFrontMatterStaticContents"/>
       <fo:flow flow-name="xsl-region-body">
         <fo:block xsl:use-attribute-sets="__frontmatter">
     <!-- set the title -->
          <fo:block xsl:use-attribute-sets="__frontmatter__title">
           <xsl:choose>
            <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
     <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
                  </xsl:when>
    <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
     <xsl:apply-templates select="$map//*[contains
                                    (@class,' bookmap/mainbooktitle ')][1]"/>
         </xsl:when>
    <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
      <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
         </xsl:when>
      <xsl:otherwise>
    <xsl:value-of select="/descendant::*[contains
          (@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
      </xsl:otherwise>
         </xsl:choose>
     </fo:block>

  <!-- set the subtitle -->
     <xsl:apply-templates select="$map//*[contains
                                          (@class,' bookmap/booktitlealt ')]"/>

        <fo:block xsl:use-attribute-sets="__frontmatter__owner">
            <xsl:apply-templates select="$map//*[contains
                                                 (@class,' bookmap/bookmeta ')]"/>
        </fo:block>

        <fo:block text-align="center" width="100%">
           <fo:external-graphic src="url({concat($artworkPrefix,
                       '/Customization/OpenTopic/common/artwork/logo.png')})"/>
         </fo:block>

    </fo:block>

   <!--<xsl:call-template name="createPreface"/>-->

           </fo:flow>
        </fo:page-sequence>
        <xsl:call-template name="createNotices"/>
    </xsl:template>
</xsl:stylesheet>
```

7. Edit the **DITA Map PDF** transformation scenario and in the **Parameters** tab, set the customization.dir parameter to `C:\Customization`.

Tip: For other specific examples, see *DITA-OT 2.x Documentation - PDF Customization Plugin*.

Customizing the Header and Footer in PDF Output

The XSLT stylesheet *DITA-OT-DIR*`/plugins/org.dita.pdf2/xsl/fo/static-content.xsl` contains templates that output the static header and footers for various parts of the PDF such as the prolog, table of contents, front matter, or body.

The templates for generating a footer for pages in the body are called `insertBodyOddFooter` or `insertBodyEvenFooter`.

These templates get the static content from resource files that depend on the language used for generating the PDF. The default resource file is *DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg/common/vars/en.xml`. These resource files contain variables (such as *Body odd footer*) that can be set to specific user values.

Instead of modifying these resource files directly, they can be overwritten with modified versions of the resources in a PDF customization directory as explained in *Customizing the PDF Output*.

Adding a Watermark to PDF Output

To add a watermark to the PDF output of a *DITA map* transformation, create a DITA-OT customization directory and use it from a **DITA Map to PDF** transformation scenario, as in the following procedure:

1. Copy the entire directory: *DITA-OT-DIR*`\plugins\org.dita.pdf2\Customization` to another location (for instance, `C:\Customization`).
2. Copy your watermark image (for example, `watermark.png`) to: `C:\Customization\common\artwork\watermark.png`.
3. Rename the `C:\Customization\catalog.xml.orig` file to: `C:\Customization\catalog.xml`.
4. Open the `catalog.xml` in Oxygen XML Editor and *uncomment* this line:

   ```
   <!--uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/-->
   ```

   The uncommented line should look like this:

   ```
   <uri name="cfg:fo/xsl/custom.xsl" uri="fo/xsl/custom.xsl"/>
   ```

5. Rename the file: `C:\Customization\fo\xsl\custom.xsl.orig` to: `C:\Customization\fo\xsl\custom.xsl`
6. Open the `C:\Customization\fo\xsl\custom.xsl` file in Oxygen XML Editor to overwrite two XSLT templates:
   - The first template is located in the XSLT stylesheet *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\static-content.xsl` and we override it specifying a watermark image for every page in the PDF content, using a *block-container* element that references the watermark image file:

     ```
     <fo:static-content flow-name="odd-body-header">
            <fo:block-container absolute-position="absolute"
               top="-2cm" left="-3cm" width="21cm" height="29.7cm"
               background-image="{concat($artworkPrefix,
     '/Customization/OpenTopic/common/artwork/watermark.png')}">
              <fo:block/>
            </fo:block-container>
           <fo:block xsl:use-attribute-sets="__body__odd__header">
               <xsl:call-template name="insertVariable">
                   <xsl:with-param name="theVariableID" select="'Body odd header'"/>
                   <xsl:with-param name="theParameters">
                      <prodname>
                          <xsl:value-of select="$productName"/>
                      </prodname>
                      <heading>
                    <fo:inline xsl:use-attribute-sets="__body__odd__header__heading">
                           <fo:retrieve-marker retrieve-class-name="current-header"/>
                    </fo:inline>
                     </heading>
                    <pagenum>
                  <fo:inline xsl:use-attribute-sets="__body__odd__header__pagenum">
                         <fo:page-number/>
                   </fo:inline>
                 </pagenum>
             </xsl:with-param>
     ```

```
      </xsl:call-template>
    </fo:block>
  </fo:static-content>

</xsl:template>
```

- The second template that we override is located in the XSLT stylesheet *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\commons.xsl` and is used for styling the first page of the output. We also override it by copying the original template content in our `custom.xsl` and adding the `block-container` element that references the watermark image file:

```
<xsl:template name="createFrontMatter_1.0">
      <fo:page-sequence master-reference="front-matter"
xsl:use-attribute-sets="__force__page__count">
          <xsl:call-template name="insertFrontMatterStaticContents"/>
          <fo:flow flow-name="xsl-region-body">
              <fo:block-container absolute-position="absolute"
                  top="-2cm" left="-3cm" width="21cm" height="29.7cm"
                  background-image="{concat($artworkPrefix,
'/Customization/OpenTopic/common/artwork/watermark.png')}">
                  <fo:block/>
              </fo:block-container>
  <fo:block xsl:use-attribute-sets="__frontmatter">
       <!-- set the title -->
    <fo:block xsl:use-attribute-sets="__frontmatter__title">
     <xsl:choose>
      <xsl:when test="$map/*[contains(@class,' topic/title ')][1]">
    <xsl:apply-templates select="$map/*[contains(@class,' topic/title ')][1]"/>
      </xsl:when>
      <xsl:when test="$map//*[contains(@class,' bookmap/mainbooktitle ')][1]">
    <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/mainbooktitle ')][1]"/>
          </xsl:when>
          <xsl:when test="//*[contains(@class, ' map/map ')]/@title">
              <xsl:value-of select="//*[contains(@class, ' map/map ')]/@title"/>
          </xsl:when>
            <xsl:otherwise>
             <xsl:value-of select="/descendant::*[contains
(@class, ' topic/topic ')][1]/*[contains(@class, ' topic/title ')]"/>
            </xsl:otherwise>
      </xsl:choose>
    </fo:block>

   <!-- set the subtitle -->
   <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/booktitlealt ')]"/>

      <fo:block xsl:use-attribute-sets="__frontmatter__owner">
         <xsl:apply-templates select="$map//*[contains
(@class,' bookmap/bookmeta ')]"/>
      </fo:block>

      </fo:block>

   <!--<xsl:call-template name="createPreface"/>-->

      </fo:flow>
        </fo:page-sequence>
        <xsl:if test="not($retain-bookmap-order)">
            <xsl:call-template name="createNotices"/>
        </xsl:if>
    </xsl:template>
```

7. Edit your **DITA Map PDF** transformation scenario. In the **Parameters** tab, set the customization.dir parameter to `C:\Customization`.

Related Information:

Adding a Watermark in DITA Map to XHTML Output on page 1906

Adding an Edit Link in PDF Output to Launch Oxygen XML Web Author

You can embed *Edit* links in the DITA Map PDF output that will automatically launch a particular document in *Oxygen XML Web Author*. A reviewer can then simply click the link and they will be redirected to the Oxygen XML Web Author editing page with that particular file open and editable.

To embed an *Edit* link in the DITA Map PDF output, follow these steps:

1. *Edit a **DITA Map PDF** transformation scenario* and open the **Parameters** tab.
2. Set values for the following parameters:
   - **editlink.remote.ditamap.url** - The URL of the DITA Map suitable for opening in Oxygen XML Web Author.
   - **editlink.web.author.url** - The URL of the Oxygen XML Web Author installation.
3. Run the transformation scenario.

Result: In the PDF output, all topics will have an **Edit** link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

Force Page Breaks Between Two Block Elements in PDF Output

Suppose that in your DITA content you have two *block elements*, such as two paragraphs:

```
<p>First para</p>
<p>Second para</p>
```

and you want to force a page break between them in the PDF output.

Here is how you can implement a DITA Open Toolkit *plugin* that would achieve this:

1. Define your custom processing instruction that marks the place where a page break should be inserted in the PDF, for example:

   ```
   <p>First para</p>
     <?pagebreak?>
   <p>Second para</p>
   ```

2. Locate the **DITA Open Toolkit** distribution and in the `plugins` directory create a new *plugin* folder (for example, *`DITA-OT-DIR`*`/plugins/pdf-page-break`).
3. In this new folder, create a new `plugin.xml` file with the following content:

   ```
   <plugin id="com.yourpackage.pagebreak">
     <feature extension="package.support.name" value="Force Page Break Plugin"/>
     <feature extension="package.support.email" value="support@youremail.com"/>
     <feature extension="package.version" value="1.0.0"/>
     <feature extension="dita.xsl.xslfo" value="pageBreak.xsl" type="file"/>
   </plugin>
   ```

   The most important feature in the *plugin* is that it will add a new XSLT stylesheet to the XSL processing that produces the PDF content.
4. In the same folder, create an XSLT stylesheet named `pageBreak.xsl` with the following content:

   ```
   <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                       xmlns:fo="http://www.w3.org/1999/XSL/Format"version="1.0">
     <xsl:template match="processing-instruction('pagebreak')">
       <fo:block break-after="page"/>
     </xsl:template>
   </xsl:stylesheet>
   ```

5. *Install your plugin in the DITA Open Toolkit.*

Customizing `note` Images in PDF

To customize the images that appear next to each type of note in the PDF output, use a *PDF customization folder* with the following procedure:

1. Copy the *`DITA-OT-DIR`*`/plugins/org.dita.pdf2/cfg/common/vars/en.xml` file to the `[CUSTOMIZATION_DIR]\common\vars` folder.
2. Edit the copied `en.xml` file and modify, for example, the path to the image for `<note>` element with the `type` attribute set to `notice` from:

   ```
   <variable id="notice Note Image
     Path">Configuration/OpenTopic/cfg/common/artwork/important.png</variable>
   ```

   to:

   ```
   <variable id="notice Note Image
     Path">Customization/OpenTopic/common/artwork/notice.gif</variable>
   ```

3. Add your custom **notice** image to `[CUSTOMIZATION_DIR]\common\artwork\notice.gif`.
4. Edit the **DITA Map PDF** transformation scenario and in the **Parameters** tab set the path for the customization.dir property to point to the customization folder. Also, set the **com.oxygenxml.use.custom.note.images** parameter to **no**.

Show Comments and Tracked Changes in PDF Output

To include comments and *tracked changes* (stored within your DITA topics) in the PDF output, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.

2. Select **DITA Map PDF** and click the **Edit** button (or use the **Duplicate** button if your *framework* is read-only).
3. In the **Parameters** tab, set the value of the show.changes.and.comments parameter to `yes`.
4. Click **OK** and then the **Apply Associated** button to run the transformation scenario.

   Result: Comment threads and tracked changes will now appear in the PDF output. Details about each comment or change will be available in the footer section for each page.

Set a Font for PDF Output Generated with FO Processor

When a *DITA map* is transformed to PDF using an FO processor and it contains some Unicode characters that cannot be rendered by the default PDF fonts, a font that is capable of rendering these characters must be configured and embedded in the PDF result.

The settings that must be modified for configuring a font for the built-in FO processor are detailed in *Add a Font to the Built-in FO Processor*.

DITA OT PDF Font Mapping

The DITA OT contains a file *DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml` that maps logical fonts used in the XSLT stylesheets to physical fonts that will be used by the FO processor to generate the PDF output.

The XSLT stylesheets used to generate the XSL-FO output contain code like this:

```
<xsl:attribute name="font-family">monospace</xsl:attribute>
```

The font-family is defined to be *monospace*, but *monospace* is just an alias. It is not a physical font name. Therefore, another stage in the PDF generation takes this *monospace* alias and looks in the `font-mappings.xml`.

If it finds a mapping like this:

```
<aliases>
      <alias name="monospace">Monospaced</alias>
 </aliases>
```

then it looks to see if the *Monospaced* has a *logical-font* definition and if so, it will use the *physical-font* specified there:

```
<logical-font name="Monospaced">
      <physical-font char-set="default">
        <font-face>Courier New, Courier</font-face>
      </physical-font>
.............
</logical-font>
```

Important:

If no alias mapping is found for a font-family specified in the XSLT stylesheets, the processing defaults to **Helvetica**.

DITA Map to PDF WYSIWYG Transformation

Oxygen XML Editor comes bundled with a DITA OT plugin that allows you to convert *DITA maps* to PDF using a CSS layout processor. Oxygen XML Editor also comes bundled with a built-in CSS-based PDF processing engine called **Chemistry**. For those who are familiar with CSS, this makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations.

Oxygen XML Editor supports the following processors (not included in the Oxygen XML Editor installation kit):

- **Oxygen Chemistry** - A built-in processor that is bundled with Oxygen XML Editor. For more information, see the *Oxygen PDF Chemistry User Guide*.
- **Prince Print with CSS** - A third-party component that needs to be purchased from *http://www.princexml.com*.
- **Antenna House Formatter** - A third-party component that needs to be purchased from *http://www.antennahouse.com/antenna1/formatter/*.

The DITA-OT plugin is located in the following directory: *DITA-OT-DIR*`/plugins/com.oxygenxml.pdf.css`.

Although it includes a set of CSS files in its `css` subfolder, when this plugin is used in Oxygen XML Editor, the CSS files located in the `${frameworks}` directory take precedence.

Creating the Transformation Scenario

To create an **DITA Map to PDF WYSIWYG** transformation scenario, follow these steps:

1. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
2. Select **DITA Map PDF - WYSIWYG**.
3. In the **CSS Processor** tab, choose the processor type. You can select between **Oxygen PDF Chemistry**, **Prince XML**, or **Antenna House**.
4. In the **Parameters** tab, configure any of the following parameters (if applicable):
   - `css.processor.path.prince` (if you are using the **Prince Print with CSS** processor) - Specifies the path to the Prince executable file that will be run to produce the PDF. If you installed Prince using its default settings, you can leave this blank.
   - `css.processor.path.antenna-house` (if you are using the **Antenna House Formatter** processor) - Specifies the path to the Antenna House executable file that will be run to produce the PDF. If you installed Antenna House using its default settings, you can leave this blank.
   - `show.changes.and.comments` - When set to `yes`, user comments, replies to comments, and *tracked changes* are published in the PDF output. The default value is no.
   - `dita.css.list` - Allows you to specify a list of CSS URLs to be used by the PDF processor (instead of the default CSS files). The files must have URL syntax and be separated using semicolons. If the value is empty, the CSS associated with the current selection from the **Styles** drop-down menu is used.
   - `args.css` - Allows you to specify a list of CSS URLs to be used in addition to those specified in the `dita.css.list` parameter OR in addition to the CSS that is currently selected in the **Styles** drop-down menu. The files must have URL syntax and be separated using semicolons. Also, the `dita.css.list` parameter must be left empty to use these files in addition to the selection in the **Styles** drop-down menu.
5. Click **OK** and run the transformation scenario.

Customizing the Styles (for Output and Editing)

If you need to change the styles in the associated CSS, make sure you install Oxygen XML Editor in a folder where you have full read and write privileges (for instance, your user home directory). This is due to the fact that the installed files are usually placed in a read-only folder (for instance, in Windows, Oxygen XML Editor is installed in the `Program Files` folder where the users do not have change rights).

To change the styles of an element you need to create an additional CSS file that will store the customization rules. Once you have created this file, you need to instruct the editor how to use this additional CSS. This can be done in two ways:

- Create an alternate CSS for the DITA document type:
  1. Follow the procedure for adding an alternate CSS file in *Customizing the Main CSS of a Framework* on page 1454.
  2. Once you have configured your CSS as an additional layer, you can *select it from the **Styles** drop-down menu (on the toolbar)*.
  3. Run the **DITA Map PDF - WYSIWYG** transformation scenario and the customization rules from the additional CSS will be visible in the produced PDF.

  This method allows you to have many customization CSS files and simply select the one that you need at any time for both the output and rendering **Author** mode while editing.
- Use the `args.css` parameter that allows you to specify a list of CSS URLs to be used in addition to the `dita.css.list` parameter:
  1. Configure a **DITA map to PDF WYSIWYG** transformation scenario, as described in the procedure *above*.
  2. In the **Parameters** tab, specify the path to your custom CSS files in the `args.css` parameter.
  3. Click **OK** and run the transformation scenario.

This method is appropriate if you just want to apply the styling customization to the output.

Tip: For more information about customizing CSS styles for PDF output, see the *Oxygen PDF Chemistry User Guide*. It offers numerous tips for customizing CSS styles even if you are not using the Chemistry processor.

Using the CSS Inspector to See Style Associated with an Element

To find the styles associated with an element, follow this procedure:

1. Open a document in the editor and select **Inspect Styles** from the contextual menu. This opens the ***CSS Inspector** view* that shows all the CSS rules that apply to the selected element.
2. Click the particular link for the CSS selector that you need to change and Oxygen XML Editor will open the CSS file and position the cursor at that selector.
3. After you identify the source of the styles you want to modify, copy the CSS rule in your customization CSS file and modify it according to your needs.

   To see the changes in **Author** mode, press **F5** to reload the document.

How to Make Remote Resources Appear in the Output When Using the Prince Processor

If your documentation references external resources (such as images that are stored on a Web-based repository) and your system is behind an HTTP(S) proxy, you may find that they do not appear in the output when using the **Prince Print with CSS** processor. To solve this, follow this procedure:

1. Edit the **`build.xml`** file that is located in *`DITA-OT-DIR`*`/plugins/com.oxygenxml.pdf.css`.
2. There are two instances in the file where a pair of arguments are commented out:

```
<!-- Please remove the comment wrapping the following two arguments
if you are behind a proxy and your documentation refers remote resources,
for example images.

Note: You also need to remove the backslash '\' that appears before the
property name: "http-proxy". That backslash is there because a sequence of
two dashes ('-') is not permited inside a comment.
-->
<!--
  <arg value="-\-http-proxy=${http.proxyHost}:${http.proxyPort}"/>
  <arg value="-\-http-proxy=${https.proxyHost}:${https.proxyPort}"/>
-->
```

3. Remove the comment in both instances.
4. Make sure you also remove the slash that appears before the property name `http-proxy` in each instance.

   Step Result: The arguments should now look like this:

```
<arg value="--http-proxy=${http.proxyHost}:${http.proxyPort}"/>
<arg value="--http-proxy=${https.proxyHost}:${https.proxyPort}"/>
```

5. Save the **`build.xml`** file.
6. Run the *DITA map to PDF WYSIWYG transformation scenario*.

   Result: Your external resources should now appear in your output.

Customizing CSS Styles Using Oxygen PDF Chemistry

Oxygen PDF Chemistry makes it very easy to style and customize the PDF output of your DITA projects without having to work with *xsl:fo* customizations. It allows you to style the PDF output by simply changing the CSS and then re-running the transformation scenario until you get the desired result.

For more information, see the *Oxygen PDF Chemistry User Guide*. It also offers numerous tips for customizing CSS styles for PDF output even if you are not using the Chemistry processor.

DITA Map to MS Office Word Transformation

Oxygen XML Editor comes bundled with a transformation scenario that allows you to convert *DITA maps* to Microsoft Office Word documents. It utilizes the ***DITA to Word plugin*** *created by Jarno Elovirta*. This *plugin* contains a Word document named **Normal.docx** (located in: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/DITA-OT2.x/plugins/com.elovirta.ooxml/resources`) that is used by the transformation scenario as a template to generate the final Word document.

Tip: You can make general modifications to the **Normal.docx** template file to alter the published output.

Configuring the Transformation Scenario

To configure an **DITA Map to MS Office Word** transformation scenario, follow these steps:

1. Open the DITA map in the ***DITA Maps Manager***.
2. Click the **Configure Transformation Scenario(s)** button from the ***DITA Maps Manager*** toolbar.
3. Select **DITA Map MS Office Word**.
4. For advanced customizations, in the **Parameters** tab you can use any of the following parameters that are unique to this transformation scenario to specify paths to files that affect the output in various ways:
   - `dotx.file` - Specifies the path to a Word template file (`.docx`) that will be used in the transformation to generate the final Word document. Set this parameter if you want to use a different template file other than the **Normal.docx** file that is used by default.
   - `document.flat.xsl` - Specifies the path to a pre-process clean-up stylesheet.
   - `core.xsl` - Specifies the path to a core metadata stylesheet.
   - `custom.xsl` - Specifies the path to a custom metadata stylesheet.
   - `document.xsl` - Specifies the path to a main document stylesheet.
   - `comments.xsl` - Specifies the path to a comments stylesheet.
   - `numbering.xsl` - Specifies the path to a list and title numbering stylesheet.
   - `footnotes.xsl` - Specifies the path to a footnote stylesheet.
   - `document.xml.xsl` - Specifies the path to a document relations metadata stylesheet.
   - `inkscape.exec` - Specifies the path to an Inkscape (open-source vector graphics editor) executable file.
5. Click **OK** and run the transformation scenario.

Result: The result of the transformation will automatically be opened in your system's default word processing application (such as Microsoft Word).

Migrating MS Office Documents to DITA on page 1930

Compiled HTML Help (CHM) Output Format

To perform a *Compiled HTML Help (CHM)* transformation, Oxygen XML Editor needs `Microsoft HTML Help Workshop` to be installed on your computer. Oxygen XML Editor automatically detects `HTML Help Workshop` and uses it.

Note: `HTML Help Workshop` might fail if the files used for transformation contain accents in their names, due to different encodings used when writing the *.hhp* and *.hhc* files. If the transformation fails to produce the CHM output but the *.hhp* (HTML Help Project) file is already generated, you can manually try to build the CHM output using `HTML Help Workshop`.

Changing the Output Encoding

Oxygen XML Editor uses the `htmlhelp.locale` parameter to correctly display specific characters of different languages in the output of the *Compiled HTML Help (CHM)* transformation. By default, the **DITA Map CHM** transformation scenario that comes bundled with Oxygen XML Editor has the `htmlhelp.locale` parameter set to `en-US`.

To customize this parameter, follow this procedure:

1. Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.
2. Select the **DITA Map CHM** transformation scenario and click the **Edit** button.
3. In the **Parameter** tab, search for the `htmlhelp.locale` parameter and change its value to the desired language tag.

   Note: The format of the `htmlhelp.locale` parameter is `LL-CC`, where `LL` represents the language code (en, for example) and `CC` represents the country code (US, for example). The language codes are contained in the `ISO 639-1` standard and the country codes are contained in the `ISO 3166-1` standard. For further details about language tags, go to *http://www.rfc-editor.org/rfc/rfc5646.txt*.

Kindle Output Format

Oxygen XML Editor requires KindleGento generate Kindle output from *DITA maps*. To install KindleGen for use by Oxygen XML Editor, follow these steps:

1. Go to *www.amazon.com/kindleformat/kindlegen* and download the zip file that matches your operating system.
2. Unzip the file on your local disk.
3. Start Oxygen XML Editor and open a *DITA map* in the ***DITA Maps Manager** view*.
4. Click the **Configure Transformation Scenario(s)** button.
5. Select the **DITA Map Kindle** transformation and press the **Edit** button to edit it.
6. Go to **Parameters** tab and set the **kindlegen.executable** parameter as the path to the *KindleGen* directory.
7. Accept the changes.

Creating New Transformation Scenarios

Defining a transformation scenario is the first step in the process of transforming a document. This section includes information on the types of scenarios that are available in Oxygen XML Editor and how to create each type of transformation.

XML Transformation with XSLT
This type of transformation specifies the transformation parameters and location of an XSLT stylesheet that is applied to the edited XML document. This scenario is useful when you develop an XML document and the XSLT document is in its final form.

To create an **XML transformation with XSLT** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu. Then click the **New** button and select **XML transformation with XSLT**.
- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **XML transformation with XSLT**.

Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

XSLT Tab

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XSLT** tab contains the following options:

XML URL

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

Note: If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the *advanced Saxon preferences page*, the XML input of the transformation is passed to that URI resolver. If the transformer engine is one of the built-in XSLT 2.0 / 3.0 engines and *the name of an initial template* is specified in the scenario, the **XML URL** field can be empty. The **XML URL** field can also be empty if you use *external XSLT processors*. Otherwise, a value is mandatory in this field.

XSL URL

Specifies the source XSL file that the transformation will use. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

Use "xml-stylesheet" declaration

If selected, the scenario applies the stylesheet specified explicitly in the XML document with the `xml-stylesheet` processing instruction. By default, this option is deselected and the transformation applies the XSLT stylesheet that is specified in the **XSL URL** field.

Transformer

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and *the external engines defined in the Custom Engines preferences page*. The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

Advanced options

Allows you to configure the *advanced options of the Saxon HE/PE/EE engine* for the current transformation scenario. To configure the same options globally, go to the *Saxon-HE/PE/EE preferences page*. For the current transformation scenario, these **Advanced options** override the options configured in that preferences page.

Parameters

Opens a ***Configure parameters** dialog box* that allows you to configure the XSLT parameters used in the current transformation. In this dialog box, you can also configure the parameters for *additional XSLT stylesheets*. If the XSLT transformation engine is custom-defined, you can not use this dialog box to configure the parameters sent to the custom engine. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XSLT engine to include the necessary parameters in the command line that starts the transformation process.

Extensions

Opens a *dialog box for configuring the XSLT extension JARS or classes* that define extension Java functions or extension XSLT elements used in the transformation.

Additional XSLT stylesheets

Opens a *dialog box for adding XSLT stylesheets* that are applied on the main stylesheet specified in the **XSL URL** field. This is useful when a chain of XSLT stylesheets must be applied to the input XML document.

XSLT Parameters

The global parameters of the XSLT stylesheet used in a transformation scenario can be configured by using the **Parameters** button in the **XSLT** tab of a new or edited transformation scenario dialog box.

The resulting dialog box includes a table that displays all the parameters of the current XSLT stylesheet, all imported and included stylesheets, and all *additional stylesheets*, along with their descriptions and current values.

You can also add, edit, and remove parameters, and you can use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the **XPath** column is selected, the parameter value is evaluated as an XPath expression before starting the XSLT transformation.

Example:

For example, you can use expressions such as:

```
doc('test.xml')//entry
//person[@atr='val']
```

Note:

1. The **doc** function solves the argument relative to the XSL stylesheet location. You can use full paths or *editor variables* (such as **${cfdu}** [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`
2. You cannot use XSLT Functions. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Edit

Opens the **Edit Parameter** dialog box that allows you to edit the selected parameter. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:

Editor Variables on page 173

XSLT Extensions

The **Extensions** button opens a dialog box that allows you to specify the *JARS* and classes that contain extension functions called from the XSLT file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

Tip: You can specify the path to the resources using wildcards (for example, `${oxygenHome}/lib/*.jar`).

An extension function called from the XSLT file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the **Move up** or **Move down** buttons.

Additional XSLT Stylesheets

Use the **Additional XSLT Stylesheets** button in the **XSLT** tab to display a list of additional XSLT stylesheets to be used in the transformation and you can add files to the list or edit existing entries. The following actions are available:

Add

Adds a stylesheet in the **Additional XSLT stylesheets** list using a file browser dialog box. You can type an *editor variable* in the file name field of the browser dialog box. The name of the stylesheet will be added in the list after the current selection.

Remove

Deletes the selected stylesheet from the **Additional XSLT stylesheets** list.

Open

Opens the selected stylesheet in a separate view.

Up

Moves the selected stylesheet up in the list.

Down

Moves the selected stylesheet down in the list.

Advanced Saxon HE/PE/EE XSLT Transformation Options

The XSLT transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as *those in the **Saxon HE/PE/EE** preferences page* but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the *global options* defined in the preferences page.

Saxon-HE/PE/EE Options

The advanced options for Saxon 9.7.0.19 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Mode ("-im")

A Saxon-specific option that sets the initial mode for the transformation.

Template ("-it")

A Saxon-specific option that sets the name of the initial XSLT template to be executed.

Use a configuration file ("-config")

Sets a Saxon 9.7.0.19 configuration file that is executed for XSLT transformation and validation processes.

Debugger trace into XPath expressions (applies to debugging sessions)

Instructs the *XSLT Debugger* to *step into* XPath expressions.

Version warnings ("-versmsg")

Warns you when the transformation is applied to an XSLT 1.0 stylesheet.

Line numbering ("-l")

Line numbers where errors occur are included in the output messages.

Expand attributes defaults ("-expand")

Specifies whether or not the attributes defined in the associated DTD or XML Schema are expanded in the output of the transformation you are executing.

DTD validation of the source ("-dtd")

Specifies whether or not the source document will be validated against their associated DTD. You can choose from the following:

- **On** - Requests DTD validation of the source file and of any files read using the `document()` function.
- **Off** - (default setting) Suppresses DTD validation.
- **Recover** - Performs DTD validation but treats the errors as non-fatal.

  Note: Any external DTD is likely to be read even if not used for validation, since DTDs can contain definitions of entities.

Recoverable errors ("-warnings")

Allows you to choose how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

Strip whitespaces ("-strip")

Allows you to choose how the *strip whitespaces* operation is handled. You can choose one of the following values:

- **All ("all")** - Strips *all* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document.
- **Ignore ("ignorable")** - Strips all *ignorable* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips *no* whitespace before further processing.

Optimization level ("-opt")

Allows you to set the optimization level. It is the value is an integer in the range of 0 (no optimization) to 10 (full optimization). This option allows optimization to be suppressed when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.7.0.19 Professional Edition (PE) and Enterprise Edition (EE) only:

Register Saxon-CE extension functions and instructions

Registers the Saxon-CE extension functions and instructions when compiling a stylesheet using the Saxon 9.7.0.19 processors.

Note: Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about *executing such a stylesheet on Saxonica's website*.

Allow calls on extension functions ("-ext")

If selected, the stylesheet is allowed to call external Java functions. This does not affect calls on integrated extension functions, including Saxon and EXSLT extension functions. This option is useful when loading an untrusted stylesheet (such as from a remote site using `http://[URL]`). It ensures that the stylesheet cannot call arbitrary Java methods and thus gain privileged access to resources on your machine.

Enable assertions ("-ea")

In XSLT 3.0, you can use the **xsl:assert** element to make assertions in the form of XPath expressions, causing a dynamic error if the assertion turns out to be false. If this option is selected, XSLT 3.0 `xsl:assert` instructions are enabled. If it is not selected (default), the assertions are ignored.

Saxon-EE Options

The advanced options that are specific for Saxon 9.7.0.19 Enterprise Edition (EE) are as follows:

XML Schema version

Use this option to change the default XML Schema version for this transformation. To change the default XML Schema version globally, *open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **XML** > **XML Parser** > **XML Schema** and use the ***Default XML Schema version** option*.

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.

- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Generate bytecode ("--generateByteCode:(on|off)")

If you select this option, Saxon-EE attempts to generate Java bytecode for evaluation of parts of a query or stylesheet that are amenable to such an action. For further details regarding this option, go to *http://www.saxonica.com/documentation9.5/index.html#!javadoc*.

Enable streaming mode

Selecting this option will allow an XSLT to run in streaming mode. It is not selected by default.

Other Options

Initializer class

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the *net.sf.saxon.lib.Initializer* interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

FO Processor Tab (XSLT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

Perform FO Processing

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in **Preferences**) during the transformation.

Input

Choose between the following options to specify which input file to use:

- **XSLT result as input** - The FO processor is applied to the result of the XSLT transformation that is defined in the **XSLT** tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an *external processor*.

Output Tab (XSLT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

Prompt for file

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

Save As

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).

Note: To set the web browser that is used for displaying HTML/XHTML pages, go to **Options** > **Preferences** > **Global**, and set it in the **Default Internet browser** field.

- **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in editor

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

Show in results view as

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with *syntax highlighting*.
- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an *integrated SVG viewer in the **Results** panel* at the bottom of the application window and renders the result as an SVG image.
- **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

  Important: When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

  - **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

XML Transformation with XQuery

This type of transformation specifies the transform parameters and location of an XQuery file that is applied to the edited XML document.

Use the **XML transformation with XQuery** scenario to apply a transformation in which an XQuery file queries an XML file for the output results.

To create an **XML transformation with XQuery** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s)** (**Ctrl + Shift + C (Command + Shift + C on OS X)**) action from the toolbar or the **Document** > **Transformation** menu. Then click the **New** button and select **XML transformation with XQuery**.
- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **XML transformation with XQuery**.

Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

XQuery Tab

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XQuery** tab contains the following options:

XML URL

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

Note: If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the *advanced Saxon preferences page*, the XML input of the transformation is passed to that URI resolver.

XQuery URL

Specifies the source XQuery file to be used for the transformation. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

Transformer

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and *the external engines defined in the Custom Engines preferences page*. The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

Advanced options

Allows you to configure the *advanced options of the Saxon HE/PE/EE engine* for the current transformation scenario. To configure the same options globally, go to the *Saxon-HE/PE/EE preferences page*. For the current transformation scenario, these **Advanced options** override the options configured in that preferences page.

Parameters

Opens the ***Configure parameters*** *dialog box* for configuring the XQuery parameters. You can use the buttons in this dialog box to add, edit, or remove parameters. If the XQuery transformation engine is custom-defined, you can not use this dialog box to set parameters. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XQuery engine to include the necessary parameters in the command line that starts the transformation process.

Extensions

Opens a *dialog box for configuring the XQuery extension JARS or classes* that define extension Java functions or extension XSLT elements used in the transformation.

XQuery Parameters

The global parameters of the XQuery file used in a transformation scenario can be configured by using the **Parameters** button in the **XQuery** tab.

The resulting dialog box includes a table that displays all the parameters of the current XQuery file, along with their descriptions and current values. You can also add, edit, and remove parameters, and use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the **XPath** column is selected, the parameter value is evaluated as an XPath expression before starting the XQuery transformation.

Example:

For example, you can use expressions such as:

```
doc('test.xml')//entry
//person[@atr='val']
```

Note:

1. The **doc** function solves the argument relative to the XQuery file location. You can use full paths or *editor variables* (such as **${cfdu}** [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`
2. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Edit

Opens the **Edit Parameter** dialog box that allows you to edit the selected parameter. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:

Editor Variables on page 173

XQuery Extensions

The **Extensions** button is used to specify the *JAR* and classes that contain extension functions called from the XQuery file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

An extension function called from the XQuery file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the **Move up** or **Move down** buttons.

Advanced Saxon HE/PE/EE XQuery Transformation Options

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as *those in the **Saxon HE/PE/EE** preferences page* but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The

advanced options configured in a transformation scenario override the *global options* defined in the preferences page.

The advanced options for Saxon 9.7.0.19 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Recoverable errors ("-warnings")

Allows you to choose how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

Strip whitespaces ("-strip")

Allows you to choose how the *strip whitespaces* operation is handled. You can choose one of the following values:

- **All ("all")** - Strips *all* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document.
- **Ignore ("ignorable")** - Strips all *ignorable* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips *no* whitespace before further processing.

Optimization level ("-opt")

Allows you to set the optimization level. It is the value is an integer in the range of 0 (no optimization) to 10 (full optimization). This option allows optimization to be suppressed when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Use linked tree model ("-tree:linked")

This option activates the linked tree model.

XQuery version ("-qversion:(1.0|3.0|3.1)")

Allows you to select the XQuery version to be used by the Saxon XQuery processor for transformation and validation scenarios.

Initializer class

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the *net.sf.saxon.lib.Initializer* interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

The following advanced options are specific for Saxon 9.7.0.19 Professional Edition (PE) and Enterprise Edition (EE) only:

Use a configuration file ("-config")

Sets a Saxon 9.7.0.19 configuration file that is used for XQuery transformation and validation scenarios.

Allow calls on extension functions ("-ext")

If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

The advanced options that are specific for Saxon 9.7.0.19 Enterprise Edition (EE) are as follows:

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.

- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Generate bytecode ("--generateByteCode:(on|off)")

If you select this option, Saxon-EE attempts to generate Java bytecode for evaluation of parts of a query or stylesheet that are amenable to such an action. For further details regarding this option, go to *http://www.saxonica.com/documentation9.5/index.html#!javadoc*.

Enable XQuery update ("-update:(on|off)")

This option controls whether or not XQuery update syntax is accepted. The default value is off.

Backup files updated by XQuery ("-backup:(on|off)")

If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the **Enable XQuery update** option is selected.

FO Processor Tab (XQuery Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

Perform FO Processing

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in **Preferences**) during the transformation.

Input

Choose between the following options to specify which input file to use:

- **XQuery result as input** - The FO processor is applied to the result of the XQuery transformation that is defined in the **XQuery** tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an *external processor*.

Output Tab (XQuery Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

Present as a sequence

Selecting this option will reduce the time necessary to fetch the full results, as it will only fetch the first chunk of the results.

Prompt for file

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

Save As

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).

Note: To set the web browser that is used for displaying HTML/XHTML pages, go to **Options** > **Preferences** > **Global**, and set it in the **Default Internet browser** field.

- **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in editor

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

Show in results view as

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with *syntax highlighting*.
- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an *integrated SVG viewer in the **Results** panel* at the bottom of the application window and renders the result as an SVG image.
- **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

  Important: When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

  - **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

DITA OT Transformation

This type of transformation specifies the parameters for an Ant transformation that executes a DITA-OT build script. Oxygen XML Editor includes a built-in version of Ant and a built-in version of DITA-OT, but other versions can be set in the scenario.

To create a **DITA OT Transformation** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s)** (**Ctrl + Shift + C (Command + Shift + C on OS X)**) action from the **DITA Maps Manager** toolbar, main toolbar, or the **Document** > **Transformation** menu. Then click the **New** button and select **DITA OT Transformation**.
- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **DITA OT Transformation**.

Both methods open the **DITA Transformation Type** dialog box that presents the list of possible outputs.

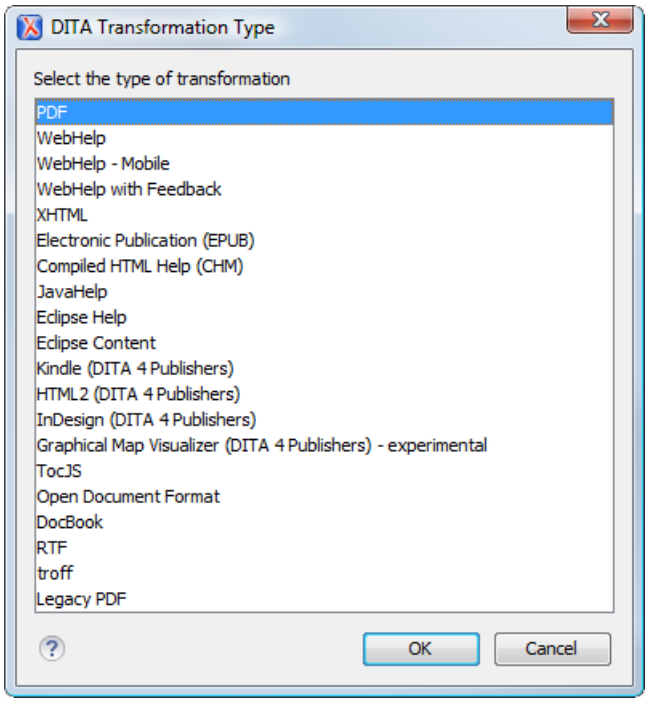

Figure 607: DITA Transformation Type Dialog Box

Select the desired type of output and click **OK**. This opens the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation. Some of these tabs are only available for certain output types (for example, a **Skins** tab is only available for **WebHelp Classic** and **WebHelp Classic with Feedback** output types, a **Templates** tab is available only for **WebHelp Responsive** and **WebHelp Responsive with Feedback**, and a **FO Processor** tab is available for PDF output).

Skins Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Skins** tab is available for DITA OT transformations with **WebHelp Classic** or **WebHelp Classic with Feedback** output types and it provides a set of predefined skins that you can use as a base for your WebHelp system output.

A *skin* is a collection of CSS properties that can alter the look of the output by changing colors, font types, borders, margins, and paddings. This allows you to rapidly adapt the look and feel of your output.

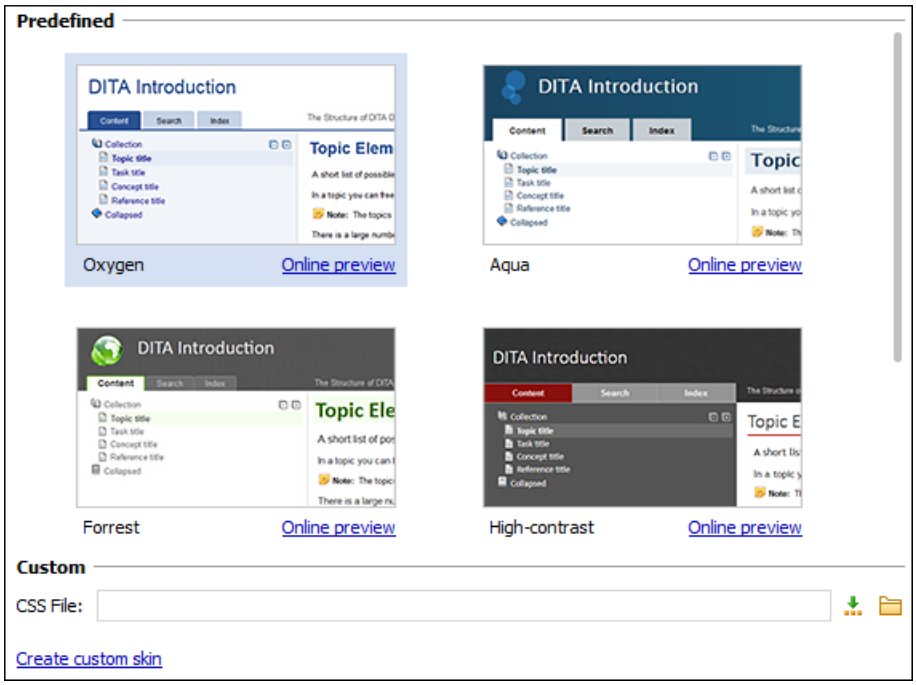

Figure 608: Skins Tab

The **Skins** tab includes the following sections:

Predefined Skins

This sections presents the predefined skins that are included in Oxygen XML Editor. The predefined skins cover a wide range of chromatic themes, ranging from a very light one to a high-contrast variant. To see how the *skin* looks when applied on a sample documentation project that is stored on the Oxygen XML Editor website, press the **Online preview** link.

Custom Skins

You can use this section to customize the look of the output.

CSS File

You can set this field to point to a custom CSS stylesheet or customized skin. A custom CSS file will overwrite a skin selection.

Note: The output can also be styled by setting the `args.css` parameter in the **Parameters tab**. The properties taken from the stylesheet referenced in this parameter take precedence over the properties declared in the skin set in the **Skins tab**.

Create custom skin

Use this link to open the ***WebHelp Skin Builder*** tool.

Templates Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Templates** tab is available for DITA OT transformations with **WebHelp Responsive** or **WebHelp Responsive with Feedback** output types and it provides a set of predefined *skins* that you can use as a base for the layout of your WebHelp system output.

A *skin* is a collection of CSS properties that can alter the look of the output by changing colors, font types, borders, margins, and paddings. This allows you to rapidly adapt the look and feel of your output. You can choose predefined skins in a *tile* style of layout or a *tree* style of layout, and you can also *add your own customized skins*.

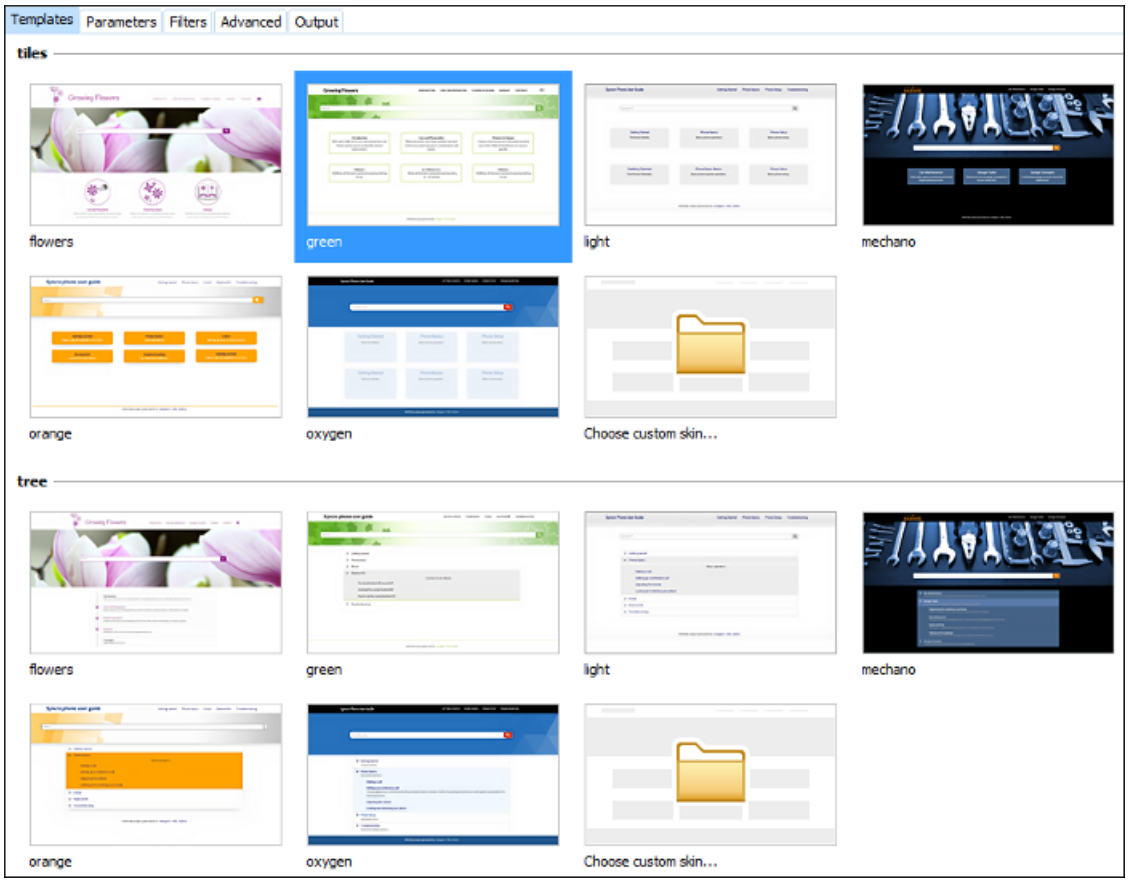

Figure 609: Templates Tab

The **Templates** tab comes by default with the following predefined collections of skins:

Tiles

This sections presents the predefined skins that are arranged in a *tiles* style of layout. These predefined skins include a variety of themes, ranging from a very light one to a high-contrast variant, and various styles. If you select **Choose custom skin**, you can select a custom CSS stylesheet to be used as your template.

Tree

This sections presents the predefined skins that are arranged in a *tree* style of layout. These predefined skins include a variety of themes, ranging from a very light one to a high-contrast variant, and various styles. If you select **Choose custom skin**, you can select a custom CSS stylesheet to be used as your template.

When you add a new collection of skins, this tab will list them.

FO Processor Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab is available for DITA OT transformations with a **PDF** output type.

This tab allows you to select an FO Processor to be used for the transformation.

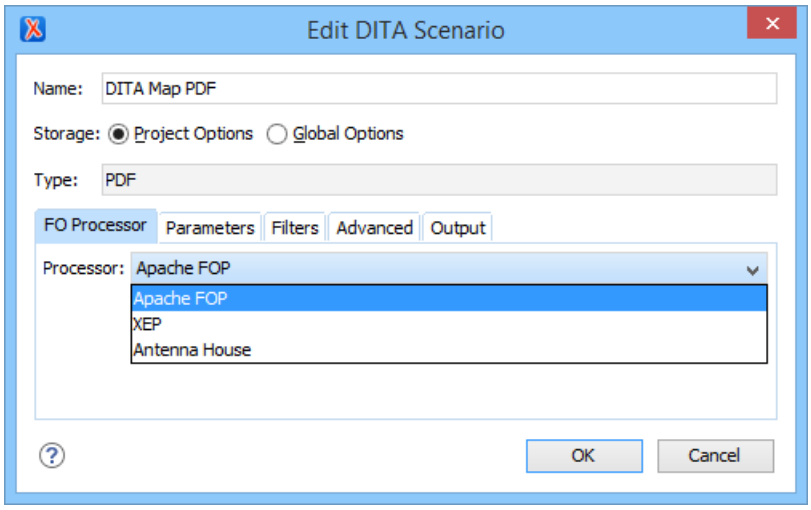

Figure 610: FO Processor Configuration Tab

You can choose one of the following processors:

Apache FOP

The default processor that comes bundled with Oxygen XML Editor.

XEP

The *RenderX* XEP processor. If XEP is already installed, Oxygen XML Editor displays the detected installation path under the drop-down menu. XEP is considered installed if it was detected in one of the following sources:

- XEP was configured as an external FO Processor in the ***FO Processors** option page*.
- The system property *com.oxygenxml.xep.location* was set to point to the XEP executable file for the platform (for example: `xep.bat` on Windows).
- XEP was installed in the *DITA-OT-DIR*`/plugins/org.dita.pdf2/lib` directory of the Oxygen XML Editor installation directory.

Antenna House

The *Antenna House* (AH Formatter) processor. If Antenna House is already installed, Oxygen XML Editordisplays the detected installation path under the drop-down menu. Antenna House is considered installed if it was detected in one of the following sources:

- Environment variable set by Antenna House installation (the newest installation version will be used).
- Antenna House was added as an external FO Processor in the Oxygen XML Editor preferences pages.

To further customize the PDF output obtained from the Antenna House processor, follow these steps:

1. **Edit** the transformation scenario.
2. Open the ***Parameters** tab*.
3. Add the `env.AXF_OPT` parameter and point to the Antenna House configuration file.

Related Information:

FO Processors Preferences on page 130

XSL-FO Processors

Parameters Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Parameters** tab allows you to configure the parameters sent to the DITA-OT build file.

The table in this tab displays all the parameters that the DITA-OT documentation specifies as available for each chosen type of transformation (for example, XHTML or PDF), along with their description and current values. You can find more information about each parameter in the *DITA OT Documentation*. You can also add, edit, and

remove parameters, and you can use the text box to filter or search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
- A file chooser and an *editor variable* selector to simplify setting a file path as the value of a parameter.

Note: To input parameter values at runtime, use the *ask editor variable* in the **Value** column.

Below the table, the following actions are available for managing parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. You can specify the **Value** of the parameter by using the ***Insert Editor Variables*** button or the **Browse** button.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Edit

Opens the **Edit Parameter** dialog box that allows you to change the value of the selected parameter or its description.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

Related Information:

DITA Open Toolkit Documentation

Filters Tab (DITA Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Filters** tab allows you to add filters to remove certain content elements from the generated output.

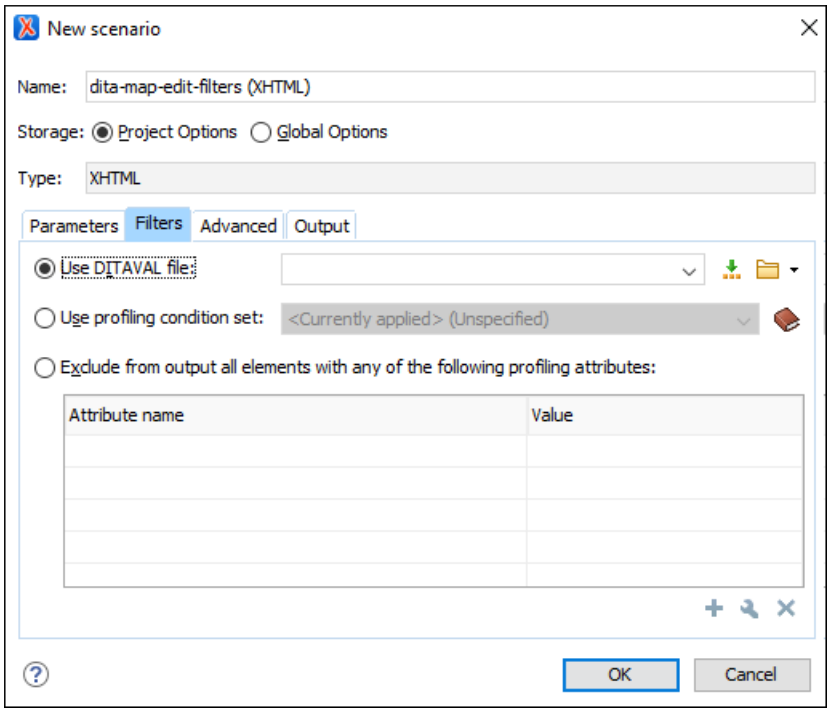

Figure 611: Edit Filters Tab

You can choose one of the following options to define filters:

Use DITAVAL file

If you already have a *DITAVAL* file associated with the *DITA map*, you can specify the file to be used when filtering content. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can find out more about constructing a *DITAVAL* file in the *DITA Documentation*.

Attention: If a filter file is specified in the `args.filter` parameter (in *the **Parameters** tab*), that file takes precedence over a *DITAVAL* file specified here.

Use profiling condition set

Sets the *profiling condition set* that will be applied to your transformation.

Exclude from output all elements with any of the following attributes

By using the **New**, **Edit**, or **Delete** buttons at the bottom of the pane, you can configure a list of attributes (name and value) to exclude all elements that contain any of these attributes from the output.

Advanced Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Advanced** tab allows you to specify advanced options for the transformation scenario.

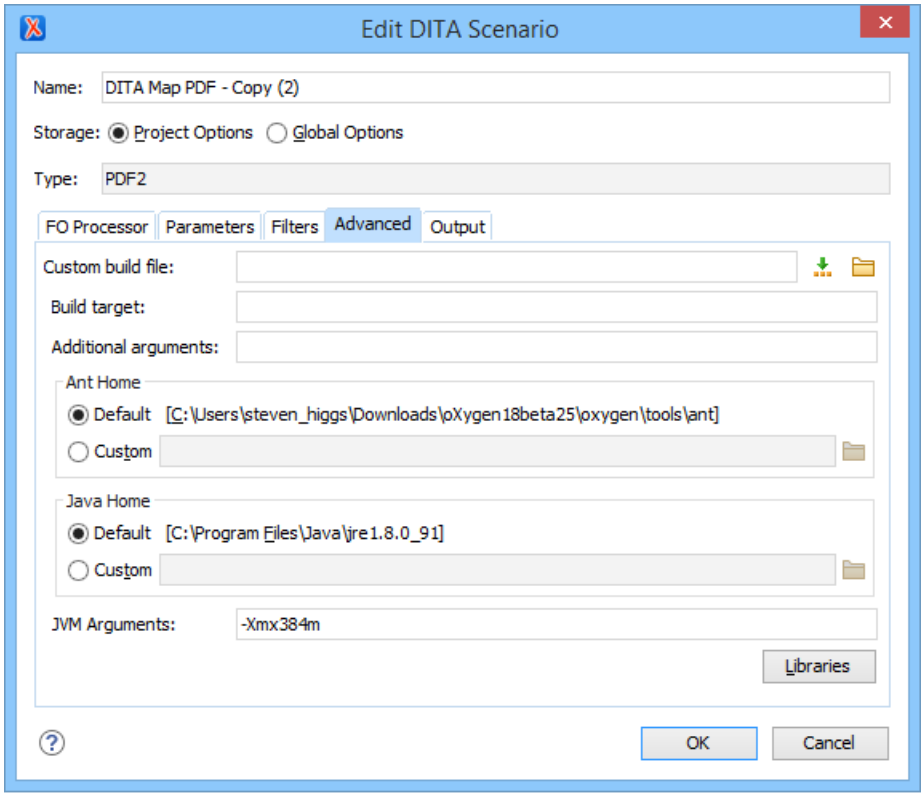

Figure 612: Advanced Settings Tab

You can specify the following parameters:

Custom build file

If you use a custom DITA-OT build file, you can specify the path to the customized build file. If empty, the `build.xml` file from the `dita.dir` parameter that is configured in the ***Parameters** tab* is used. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Build target

Optionally, you can specify a build target for the build file. If no target is specified, the default `init` target is used.

Additional arguments

You can specify additional command line arguments to be passed to the transformation (such as -verbose).

Ant Home

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the *Ant preferences page*.

Java Home

You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

Note: It may be possible that the used Java version is incompatible with the DITA Open Toolkit engine. For example, DITA OT 1.8 and older requires Java 1.6 or later, while DITA OT 2.0 and newer requires Java 1.7 or newer. Thus, if you encounter related errors running the transformation, consider installing a Java VM that is supported by the DITA OT publishing engine and using it in the **Java Home** text field.

JVM Arguments

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. For example, if it is set to -Xmx384m, the transformation process is allowed to use 384 megabytes of memory. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid *Out of Memory* error messages (**OutOfMemoryError**).

Libraries

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (*JAR* files or additional class paths) to be used by the Ant transformer.

Tip: You can specify the path to the additional libraries using wildcards (for example, `${oxygenHome}/lib/*.jar`).

Output Tab (DITA OT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab allows you to configure options that are related to the location where the output is generated.

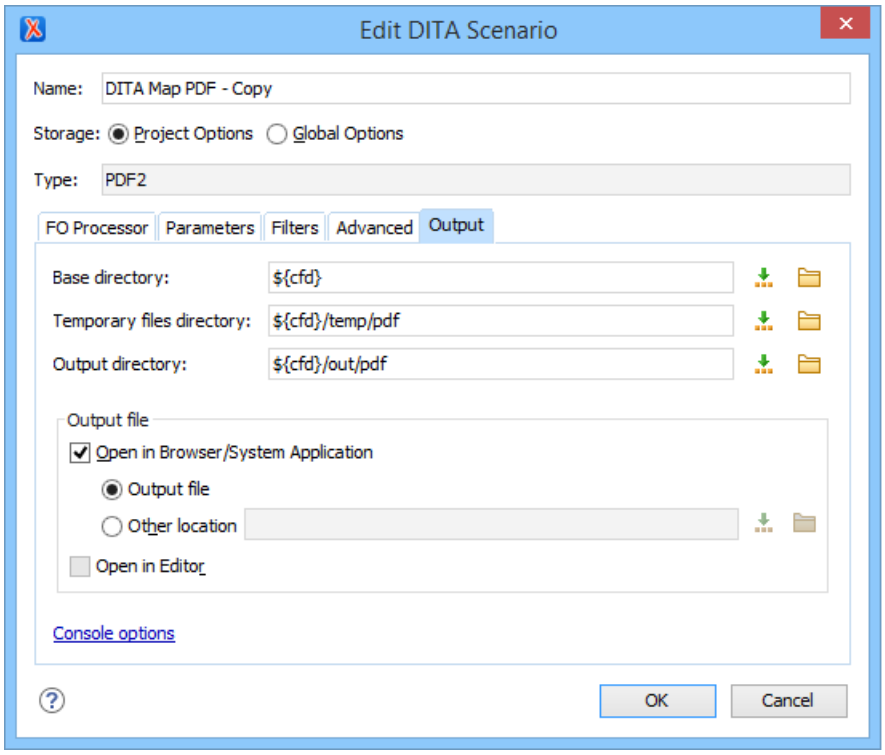

Figure 613: Output Settings Tab

You can specify the following parameters:

Base directory

All the relative paths that appear as values in parameters are considered relative to the base directory. The default value is the directory where the transformed map is located. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Temporary files directory

This directory is used to store pre-processed temporary files until the final output is obtained. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Output directory

The folder where the content of the final output is stored. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Note: If the *DITA map* or topic is opened from a remote location or a ZIP file, the parameters must specify absolute paths.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).

Note: To set the web browser that is used for displaying HTML/XHTML pages, go to **Options** > **Preferences** > **Global**, and set it in the **Default Internet browser** field.

- **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in editor

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

At the bottom of the pane there is a link to the *Console options* preferences page that contains options to control the display of the console output received from the publishing engine.

Troubleshooting DITA Transformation Errors

If a DITA transformation results in errors or warnings, the information is displayed in the message panel at the bottom of the editor. The information includes the severity, description of the problem, the name of the resource, and the path of the resource.

To help prevent and solve DITA transformation problems, follow these steps:

1. *Validate the DITA map* by using the **Validate and Check for Completeness** action that is available on the ***DITA Maps Manager*** toolbar and in the **DITA Maps** menu.
2. If this action results in validation errors, solve them prior to executing the transformation. Also, you should pay attention to the warning messages because they may identify problems in the transformation.
3. *Run the DITA transformation scenario*.
4. If the transformation results in errors or warnings, they are displayed in the ***Results** panel* at the bottom of the editor. The following information is presented to help you troubleshoot the problems:
   - **Severity** - The first column displays the following icons that indicate the severity of the problem:
     - **Informational** - The transformation encountered a condition of which you should be aware.
     - **Warning** - The transformation encountered a problem that should be corrected.
     - **Error** - The transformation encountered a more severe problem, and the output is affected or cannot be generated.
   - **Info** - You can click the **See More** icon to open a web page that contains details about DITA-OT error messages.
   - **Description** - A description of the problem.
   - **Resource** - The name of the transformation resource.
   - **System ID** - The path of the transformation resource.
5. Use this information or other resources from the online DITA-OT community to solve the transformation problems before re-executing the transformation scenario.
6. If you need to contact the Oxygen technical support team, they will need you to send the entire transformation scenario execution log. To obtain it:
   a. Go to the **Options** > **Preferences** > **DITA** preferences page and set the **Show console output** option to **Always**.
   b. Execute the transformation scenario again. The console output messages are displayed in the **DITA OT** view.
   c. Copy the entire log, save it in a text file, then send it to the Oxygen technical support team.
   d. After your issue has been solved, go back to the **Options** > **Preferences** > **DITA** preferences page and set the **Show console output** option to **When build fails**.

Ant Transformation

This type of transformation allows you to configure the options and parameters of an Ant build script.

An Ant transformation scenario is usually associated with an Ant build script. Oxygen XML Editor runs an Ant transformation scenario as an external process that executes the Ant build script with the built-in Ant distribution (*Apache Ant* version 1.8.2) that is included with the application, or optionally with a custom Ant distribution configured in the scenario.

To create an Ant transformation scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu. Then click the **New** button and select **ANT transformation**.

- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **ANT transformation**.

Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

Related Information:

Transforming Ant Build Files on page 758

Options Tab (Ant Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Options** tab allows you to specify the following options:

Working directory

The path of the current directory of the Ant external process. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Build file

The Ant script file that is the input of the Ant external process. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Build target

Optionally, you can specify a build target for the Ant script file. If no target is specified, the Ant target that is specified as the default in the Ant script file is used.

Additional arguments

You can specify additional command line arguments to be passed to the transformation (such as -verbose).

Ant Home

You can choose between the default or custom Ant installation to run the transformation. The default path can be configured in the *Ant preferences page*.

Java Home

You can choose between the default or custom Java installation to run the transformation. The default path is the Java installation that is used by Oxygen XML Editor.

JVM Arguments

This parameter allows you to set specific parameters for the Java Virtual Machine used by Ant. For example, if it is set to -Xmx384m, the transformation process is allowed to use 384 megabytes of memory. When performing a large transformation, you may want to increase the memory allocated to the Java Virtual Machine. This will help avoid *Out of Memory* error messages (**OutOfMemoryError**).

Libraries

By default, Oxygen XML Editor adds libraries (as high priority) that are not transformation-dependent and also patches for certain DITA Open Toolkit bugs. You can use this button to specify additional libraries (*JAR* files or additional class paths) to be used by the Ant transformer.

Tip: You can specify the path to the additional libraries using wildcards (for example, `${oxygenHome}/lib/*.jar`).

Parameters Tab (Ant Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Parameters** tab allows you to configure the parameters that are accessible as Ant properties in the Ant build script.

The table displays all the parameters that are available in the Ant build script, along with their description and current values. You can also add, edit, and remove parameters, and use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

Depending on the type of a parameter, its value can be one of the following:

- A simple text field for simple parameter values.
- A combo box with some predefined values.
- A file chooser and an *editor variable* selector to simplify setting a file path as the value of a parameter.

Note: To input parameter values at runtime, use the *ask editor variable* in the **Value** column.

Below the table, the following actions are available for managing parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. You can specify the **Value** of the parameter by using the ***Insert Editor Variables*** button or the **Browse** button.

Edit

Opens the **Edit Parameter** dialog box that allows you to change the value of the selected parameter or its description.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

These parameters are also available for the built-in validation processor and the *Content Completion Assistant*.

Related Information:

Content Completion in Ant Build Files on page 759

Output Tab (Ant Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

Open

Allows you to specify the file to open automatically when the transformation is finished. This is usually the output file of the Ant process. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

- **In System Application** - The file specified in the **Open** text box is opened in the system application that is set in the operating system as the default application for that type of file (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).
- **In Editor** - The file specified in the **Open** text box is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor).

Show console output

Allows you to specify when to display the console output log in the message panel at the bottom of the editor. The following options are available:

- **When build fails** - Displays the console output log only if the build fails.
- **Always** - Displays the console output log, regardless of whether or not the build fails.

XSLT Transformation
This type of transformation specifies the parameters and location of an XML document that the edited XSLT stylesheet is applied on. This scenario is useful when you develop an XSLT document and the XML document is in its final form.

To create an **XSLT transformation** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu. Then click the **New** button and select **XSLT transformation**.
- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **XSLT transformation**.

Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

XSLT Tab

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XSLT** tab contains the following options:

XML URL

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

Note: If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the *advanced Saxon preferences page*, the XML input of the transformation is passed to that URI resolver. If the transformer engine is one of the built-in XSLT 2.0 / 3.0 engines and *the name of an initial template* is specified in the scenario, the **XML URL** field can be empty. The **XML URL** field can also be empty if you use *external XSLT processors*. Otherwise, a value is mandatory in this field.

XSL URL

Specifies the source XSL file that the transformation will use. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

Use "xml-stylesheet" declaration

If selected, the scenario applies the stylesheet specified explicitly in the XML document with the `xml-stylesheet` processing instruction. By default, this option is deselected and the transformation applies the XSLT stylesheet that is specified in the **XSL URL** field.

Transformer

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and *the external engines defined in the Custom Engines preferences page*. The engine you choose is used as the default transformation engine. Also, if an XSLT or

XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

Advanced options

Allows you to configure the *advanced options of the Saxon HE/PE/EE engine* for the current transformation scenario. To configure the same options globally, go to the *Saxon-HE/PE/EE preferences page*. For the current transformation scenario, these **Advanced options** override the options configured in that preferences page.

Parameters

Opens a ***Configure parameters** dialog box* that allows you to configure the XSLT parameters used in the current transformation. In this dialog box, you can also configure the parameters for *additional XSLT stylesheets*. If the XSLT transformation engine is custom-defined, you can not use this dialog box to configure the parameters sent to the custom engine. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XSLT engine to include the necessary parameters in the command line that starts the transformation process.

Extensions

Opens a *dialog box for configuring the XSLT extension JARS or classes* that define extension Java functions or extension XSLT elements used in the transformation.

Additional XSLT stylesheets

Opens a *dialog box for adding XSLT stylesheets* that are applied on the main stylesheet specified in the **XSL URL** field. This is useful when a chain of XSLT stylesheets must be applied to the input XML document.

XSLT Parameters

The global parameters of the XSLT stylesheet used in a transformation scenario can be configured by using the **Parameters** button in the **XSLT** tab of a new or edited transformation scenario dialog box.

The resulting dialog box includes a table that displays all the parameters of the current XSLT stylesheet, all imported and included stylesheets, and all *additional stylesheets*, along with their descriptions and current values. You can also add, edit, and remove parameters, and you can use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the **XPath** column is selected, the parameter value is evaluated as an XPath expression before starting the XSLT transformation.

Example:

For example, you can use expressions such as:

```
doc('test.xml')//entry
//person[@atr='val']
```

Note:

1. The **doc** function solves the argument relative to the XSL stylesheet location. You can use full paths or *editor variables* (such as **${cfdu}** [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`
2. You cannot use XSLT Functions. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Edit

Opens the **Edit Parameter** dialog box that allows you to edit the selected parameter. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:
Editor Variables on page 173

XSLT Extensions

The **Extensions** button opens a dialog box that allows you to specify the *JARS* and classes that contain extension functions called from the XSLT file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

Tip: You can specify the path to the resources using wildcards (for example, `${oxygenHome}/lib/*.jar`).

An extension function called from the XSLT file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the **Move up** or **Move down** buttons.

Additional XSLT Stylesheets

Use the **Additional XSLT Stylesheets** button in the **XSLT** tab to display a list of additional XSLT stylesheets to be used in the transformation and you can add files to the list or edit existing entries. The following actions are available:

Add

Adds a stylesheet in the **Additional XSLT stylesheets** list using a file browser dialog box. You can type an *editor variable* in the file name field of the browser dialog box. The name of the stylesheet will be added in the list after the current selection.

Remove

Deletes the selected stylesheet from the **Additional XSLT stylesheets** list.

Open

Opens the selected stylesheet in a separate view.

Up

Moves the selected stylesheet up in the list.

Down

Moves the selected stylesheet down in the list.

Advanced Saxon HE/PE/EE XSLT Transformation Options

The XSLT transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as *those in the **Saxon HE/PE/EE** preferences page* but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the *global options* defined in the preferences page.

Saxon-HE/PE/EE Options

The advanced options for Saxon 9.7.0.19 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Mode ("-im")

A Saxon-specific option that sets the initial mode for the transformation.

Template ("-it")

A Saxon-specific option that sets the name of the initial XSLT template to be executed.

Use a configuration file ("-config")

Sets a Saxon 9.7.0.19 configuration file that is executed for XSLT transformation and validation processes.

Debugger trace into XPath expressions (applies to debugging sessions)

Instructs the *XSLT Debugger* to *step into* XPath expressions.

Version warnings ("-versmsg")

Warns you when the transformation is applied to an XSLT 1.0 stylesheet.

Line numbering ("-l")

Line numbers where errors occur are included in the output messages.

Expand attributes defaults ("-expand")

Specifies whether or not the attributes defined in the associated DTD or XML Schema are expanded in the output of the transformation you are executing.

DTD validation of the source ("-dtd")

Specifies whether or not the source document will be validated against their associated DTD. You can choose from the following:

- **On** - Requests DTD validation of the source file and of any files read using the `document()` function.
- **Off** - (default setting) Suppresses DTD validation.
- **Recover** - Performs DTD validation but treats the errors as non-fatal.

  Note: Any external DTD is likely to be read even if not used for validation, since DTDs can contain definitions of entities.

Recoverable errors ("-warnings")

Allows you to choose how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

Strip whitespaces ("-strip")

Allows you to choose how the *strip whitespaces* operation is handled. You can choose one of the following values:

- **All ("all")** - Strips *all* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document.
- **Ignore ("ignorable")** - Strips all *ignorable* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips *no* whitespace before further processing.

Optimization level ("-opt")

Allows you to set the optimization level. It is the value is an integer in the range of 0 (no optimization) to 10 (full optimization). This option allows optimization to be suppressed when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Saxon-PE/EE Options

The following advanced options are specific for Saxon 9.7.0.19 Professional Edition (PE) and Enterprise Edition (EE) only:

Register Saxon-CE extension functions and instructions

Registers the Saxon-CE extension functions and instructions when compiling a stylesheet using the Saxon 9.7.0.19 processors.

Note: Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about *executing such a stylesheet on Saxonica's website*.

Allow calls on extension functions ("-ext")

If selected, the stylesheet is allowed to call external Java functions. This does not affect calls on integrated extension functions, including Saxon and EXSLT extension functions. This option is useful when loading an untrusted stylesheet (such as from a remote site using `http://[URL]`). It ensures that the stylesheet cannot call arbitrary Java methods and thus gain privileged access to resources on your machine.

Enable assertions ("-ea")

In XSLT 3.0, you can use the **xsl:assert** element to make assertions in the form of XPath expressions, causing a dynamic error if the assertion turns out to be false. If this option is selected, XSLT 3.0 `xsl:assert` instructions are enabled. If it is not selected (default), the assertions are ignored.

Saxon-EE Options

The advanced options that are specific for Saxon 9.7.0.19 Enterprise Edition (EE) are as follows:

XML Schema version

Use this option to change the default XML Schema version for this transformation. To change the default XML Schema version globally, *open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **XML** > **XML Parser** > **XML Schema** and use the ***Default XML Schema version** option*.

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Generate bytecode ("--generateByteCode:(on|off)")

If you select this option, Saxon-EE attempts to generate Java bytecode for evaluation of parts of a query or stylesheet that are amenable to such an action. For further details regarding this option, go to *http://www.saxonica.com/documentation9.5/index.html#!javadoc*.

Enable streaming mode

Selecting this option will allow an XSLT to run in streaming mode. It is not selected by default.

Other Options

Initializer class

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the *net.sf.saxon.lib.Initializer* interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

FO Processor Tab (XSLT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

Perform FO Processing

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in **Preferences**) during the transformation.

Input

Choose between the following options to specify which input file to use:

- **XSLT result as input** - The FO processor is applied to the result of the XSLT transformation that is defined in the **XSLT** tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an *external processor*.

Output Tab (XSLT Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

Prompt for file

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

Save As

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).

Note: To set the web browser that is used for displaying HTML/XHTML pages, go to **Options** > **Preferences** > **Global**, and set it in the **Default Internet browser** field.

- **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in editor

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

Show in results view as

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with *syntax highlighting*.
- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an *integrated SVG viewer in the **Results** panel* at the bottom of the application window and renders the result as an SVG image.

- **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

  Important: When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

  - **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

XProc Transformation
This type of transformation specifies the parameters and location of an XProc script.

A sequence of transformations described by an XProc script can be executed with an XProc transformation scenario. To create an **XProc transformation** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu. Then click the **New** button and select **XProc transformation**.
- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **XProc transformation**.

Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

XProc Tab

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XProc** tab contains the following options:

XProc URL

Specify the source XSL file to be used by the transformation. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

Processor

Allows you to select the XProc engine to be used for the transformation. You can select the built-in *Calabash* engine or a custom engine that is *configured in the **Preferences** dialog box*.

Inputs Tab (XProc Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Inputs** tab contains a list with the ports that the XProc script uses to read input data. Use the **Filter** text box to search for a specific term in the entire ports collection.

Each input port has an assigned name in the XProc script. The XProc engine reads data from the URL specified in the **URL** column.

The following actions are available for managing the input ports:

New

Opens an **Edit** dialog box that allows you to add a new port and its URL. The *built-in editor variables* and *custom editor variables* can be used to specify the URL.

Edit

Opens an **Edit** dialog box that allows you to modify the selected port and its URL. The *built-in editor variables* and *custom editor variables* can be used to specify the URL.

Delete

Removes the selected port from the list. It is available only for new ports that have been added to the list.

Parameters Tab (XProc Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Parameters** tab presents a list of ports and parameters collected from the XProc script. The tab is divided into three sections:

List of Ports

In this section, you can use the **New** and **Delete** buttons to add or remove ports.

List of Parameters

This section presents a list of parameters for each port and includes columns for the parameter name, namespace URI, and its value. Use the **Filter** text box to search for a specific term in the entire parameters collection. You can use the **New** and **Delete** buttons to add or remove parameters. You can edit the value of each cell in this table by double-clicking the cell. You can also sort the parameters by clicking the column headers.

Editor Variable Information

The *built-in editor variables* and *custom editor variables* can be used for specifying the URI. The message pane at the bottom of the dialog box provides more information about the editor variables that can be used.

Outputs Tab (XProc Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Outputs** tab displays a list of output ports (along with the URL) collected from the XProc script. Use the **Filter** text box to search for a specific term in the entire ports collection. You can also sort the columns by clicking the column headers.

The following actions are available for managing the output ports:

New

Opens an **Edit** dialog box that allows you to add a new output port and its URL. An *editor variable* can be inserted for the URL by using the **Insert Editor Variables** button. There is also a **Show in transformation results view** option that allows you to select whether or not the results will be displayed in the output ***Results view***.

Edit

Opens an **Edit** dialog box that allows you to edit an existing output port and its URL. An *editor variable* can be inserted for the URL by using the **Insert Editor Variables** button. There is also a **Show in transformation results view** option that allows you to select whether or not the results will be displayed in the output ***Results view***.

Delete

Removes the selected output port from the list. It is available only for new ports that have been added to the list.

Additional options that are available at the bottom of this tab include:

Open in Editor

If this option is selected, the XProc transformation result is automatically opened in an editor panel.

Open in Browser/System Application

If this option is selected, you can specify a file to be opened at the end of the XProc transformation in the browser or system application that is associated with the file type. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list.

Results

The result of the XProc transformation can be displayed as a sequence in an output view with two sections:

- A list with the output ports on the left side.
- The content that correspond to the selected output port on the right side.

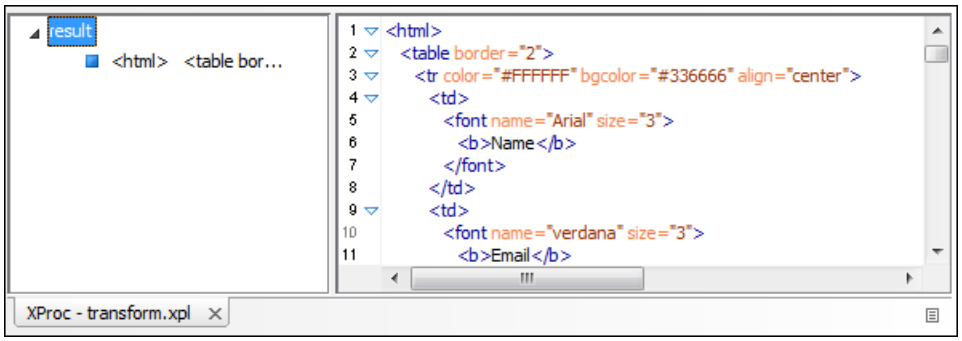

Figure 614: XProc Transformation Results View

Options Tab (XProc Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Options** tab displays a list of the options collected from the XProc script. The tab is divided into two sections:

List of Options

This section presents a list of options and includes columns for the option name, namespace URI, and its value. Use the **Filter** text box to search for a specific term in the entire options collection. You can use the **New** and **Delete** buttons to add or remove options. You can edit the value of each cell in this table by double-clicking the cell. You can also sort the parameters by clicking the column headers. The names of edited options are displayed in bold.

Editor Variable Information

The *built-in editor variables* and *custom editor variables* can be used for specifying the URI. This section provides more information about the editor variables that can be used.

XQuery Transformation

This type of transformation specifies the parameters and location of an XML source that the edited XQuery file is applied on.

Note: When the XML source is a native XML database, the source field of the scenario is empty because the XML data is read with XQuery-specific functions, such as `document()`. When the XML source is a local XML file, the URL of the file is specified in the input field of the scenario.

To create an **XQuery transformation** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu. Then click the **New** button and select **XQuery transformation**.
- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **XQuery transformation**.

Both methods open the **New Scenario** dialog box.

The upper part of the dialog box allows you to specify the **Name** of the transformation scenario and the following **Storage** options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

The lower part of the dialog box contains several tabs that allow you to configure the options that control the transformation.

XQuery Tab

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **XQuery** tab contains the following options:

XML URL

Specifies the source XML file. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, then the file is used directly from its remote location.

Note: If the transformer engine is Saxon 9.x and a custom URI resolver is configured in the *advanced Saxon preferences page*, the XML input of the transformation is passed to that URI resolver.

XQuery URL

Specifies the source XQuery file to be used for the transformation. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel. This URL is resolved through the catalog resolver. If the catalog does not have a mapping for the URL, the file is used directly from its remote location.

Transformer

This drop-down menu presents all the transformation engines available to Oxygen XML Editor for performing a transformation. These include the built-in engines and *the external engines defined in the Custom Engines preferences page*. The engine you choose is used as the default transformation engine. Also, if an XSLT or XQuery document does not have an associated validation scenario, this transformation engine is used in the validation process (if it provides validation support).

Advanced options

Allows you to configure the *advanced options of the Saxon HE/PE/EE engine* for the current transformation scenario. To configure the same options globally, go to the *Saxon-HE/PE/EE preferences page*. For the current transformation scenario, these **Advanced options** override the options configured in that preferences page.

Parameters

Opens the ***Configure parameters*** *dialog box* for configuring the XQuery parameters. You can use the buttons in this dialog box to add, edit, or remove parameters. If the XQuery transformation engine is custom-defined, you can not use this dialog box to set parameters. Instead, you can copy all parameters from the dialog box using contextual menu actions and edit the custom XQuery engine to include the necessary parameters in the command line that starts the transformation process.

Extensions

Opens a *dialog box for configuring the XQuery extension JARS or classes* that define extension Java functions or extension XSLT elements used in the transformation.

XQuery Parameters

The global parameters of the XQuery file used in a transformation scenario can be configured by using the **Parameters** button in the **XQuery** tab.

The resulting dialog box includes a table that displays all the parameters of the current XQuery file, along with their descriptions and current values. You can also add, edit, and remove parameters, and use the **Filter** text box to search for a specific term in the entire parameters collection. Note that edited parameters are displayed with their name in bold.

If the **XPath** column is selected, the parameter value is evaluated as an XPath expression before starting the XQuery transformation.

Example:

For example, you can use expressions such as:

```
doc('test.xml')//entry
//person[@atr='val']
```

Note:

1. The **doc** function solves the argument relative to the XQuery file location. You can use full paths or *editor variables* (such as **${cfdu}** [current file directory]) to specify other locations: `doc('${cfdu}/test.xml')//*`
2. Only XPath functions are allowed.

Below the table, the following actions are available for managing the parameters:

New

Opens the **Add Parameter** dialog box that allows you to add a new parameter to the list. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Edit

Opens the **Edit Parameter** dialog box that allows you to edit the selected parameter. An *editor variable* can be inserted in the text box using the **Insert Editor Variables** button. If the **Evaluate as XPath** option is selected, the parameter will be evaluated as an XPath expression.

Unset

Resets the selected parameter to its default value. Available only for edited parameters with set values.

Delete

Removes the selected parameter from the list. It is available only for new parameters that have been added to the list.

The bottom panel presents the following:

- The default value of the parameter selected in the table.
- A description of the parameter, if available.
- The system ID of the stylesheet that declares it.

Related Information:

Editor Variables on page 173

XQuery Extensions

The **Extensions** button is used to specify the *JAR* and classes that contain extension functions called from the XQuery file of the current transformation scenario. You can use the **Add**, **Edit**, and **Remove** buttons to configure the extensions.

An extension function called from the XQuery file of the current transformation scenario will be searched, in the specified extensions, in the order displayed in this dialog box. To change the order of the items, select the item to be moved and press the **Move up** or **Move down** buttons.

Advanced Saxon HE/PE/EE XQuery Transformation Options

The XQuery transformation scenario allows you to configure advanced options that are specific for the Saxon HE (Home Edition), PE (Professional Edition), and EE (Enterprise Edition) engines. They are the same options as *those in the **Saxon HE/PE/EE** preferences page* but they are configured as a specific set of transformation options for each transformation scenario, while the values set in the preferences page apply as global options. The advanced options configured in a transformation scenario override the *global options* defined in the preferences page.

The advanced options for Saxon 9.7.0.19 Home Edition (HE), Professional Edition (PE), and Enterprise Edition (EE) are as follows:

Recoverable errors ("-warnings")

Allows you to choose how dynamic errors are handled. The following options can be selected:

- **Recover silently ("silent")** - Continues processing without reporting the error.
- **Recover with warnings ("recover")** - Issues a warning but continues processing.
- **Signal the error and do not attempt recovery ("fatal")** - Issues an error and stops processing.

Strip whitespaces ("-strip")

Allows you to choose how the *strip whitespaces* operation is handled. You can choose one of the following values:

- **All ("all")** - Strips *all* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document.
- **Ignore ("ignorable")** - Strips all *ignorable* whitespace text nodes from source documents before any further processing, regardless of any `xml:space` attributes in the source document. Whitespace text nodes are ignorable if they appear in elements defined in the DTD or schema as having element-only content.
- **None ("none")** - Strips *no* whitespace before further processing.

Optimization level ("-opt")

Allows you to set the optimization level. It is the value is an integer in the range of 0 (no optimization) to 10 (full optimization). This option allows optimization to be suppressed when reducing the compiling time is important, optimization conflicts with debugging, or optimization causes extension functions with side-effects to behave unpredictably.

Use linked tree model ("-tree:linked")

This option activates the linked tree model.

XQuery version ("-qversion:(1.0|3.0|3.1)")

Allows you to select the XQuery version to be used by the Saxon XQuery processor for transformation and validation scenarios.

Initializer class

Equivalent to the `-init` Saxon command-line argument. The value is the name of a user-supplied class that implements the *net.sf.saxon.lib.Initializer* interface. This initializer is called during the initialization process, and may be used to set any options required on the configuration programmatically. It is particularly useful for tasks such as registering extension functions, collations, or external object models, especially in Saxon-HE where the option cannot be set via a configuration file. Saxon only calls the initializer when running from the command line, but the same code may be invoked to perform initialization when running user application code.

The following advanced options are specific for Saxon 9.7.0.19 Professional Edition (PE) and Enterprise Edition (EE) only:

Use a configuration file ("-config")

Sets a Saxon 9.7.0.19 configuration file that is used for XQuery transformation and validation scenarios.

Allow calls on extension functions ("-ext")

If selected, calls on external functions are allowed. Selecting this option is recommended in an environment where untrusted stylesheets may be executed. It also disables user-defined extension elements and the writing of multiple output files, both of which carry similar security risks.

The advanced options that are specific for Saxon 9.7.0.19 Enterprise Edition (EE) are as follows:

Validation of the source file ("-val")

Requests schema-based validation of the source file and of any files read using `document()` or similar functions. It can have the following values:

- **Schema validation ("strict")** - This mode requires an XML Schema and allows for parsing the source documents with strict schema-validation enabled.
- **Lax schema validation ("lax")** - If an XML Schema is provided, this mode allows for parsing the source documents with schema-validation enabled but the validation will not fail if, for example, element declarations are not found.
- **Disable schema validation** - This specifies that the source documents should be parsed with schema-validation disabled.

Validation errors in the result tree treated as warnings ("-outval")

Normally, if validation of result documents is requested, a validation error is fatal. Selecting this option causes such validation failures to be treated as warnings.

Write comments for non-fatal validation errors of the result document

The validation messages for non-fatal errors are written (wherever possible) as a comment in the result document itself.

Generate bytecode ("--generateByteCode:(on|off)")

If you select this option, Saxon-EE attempts to generate Java bytecode for evaluation of parts of a query or stylesheet that are amenable to such an action. For further details regarding this option, go to *http://www.saxonica.com/documentation9.5/index.html#!javadoc*.

Enable XQuery update ("-update:(on|off)")

This option controls whether or not XQuery update syntax is accepted. The default value is off.

Backup files updated by XQuery ("-backup:(on|off)")

If selected, backup versions for any XML files updated with an XQuery Update are generated. This option is available when the **Enable XQuery update** option is selected.

FO Processor Tab (XQuery Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **FO Processor** tab contains the following options:

Perform FO Processing

Specifies whether or not an FO processor is applied (either the built-in Apache FOP engine or an external engine defined in **Preferences**) during the transformation.

Input

Choose between the following options to specify which input file to use:

- **XQuery result as input** - The FO processor is applied to the result of the XQuery transformation that is defined in the **XQuery** tab.
- **XML URL as input** - The FO processor is applied to the input XML file.

Method

The output format of the FO processing. The available options depend on the selected processor type.

Processor

Specifies the FO processor to be used for the transformation. It can be the built-in Apache FOP processor or an *external processor*.

Output Tab (XQuery Transformations)

When you *create a new transformation scenario* or *edit an existing one*, a configuration dialog box allows you to customize the transformation with various options in several tabs.

The **Output** tab contains the following options:

Present as a sequence

Selecting this option will reduce the time necessary to fetch the full results, as it will only fetch the first chunk of the results.

Prompt for file

At the end of the transformation, a file browser dialog box is displayed for specifying the path and name of the file that stores the transformation result.

Save As

The path of the file where the result of the transformation is stored. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in Browser/System Application

If selected, Oxygen XML Editor automatically opens the result of the transformation in a system application associated with the file type of the result (for example, in Windows *PDF* files are often opened in *Acrobat Reader*).

Note: To set the web browser that is used for displaying HTML/XHTML pages, go to **Options** > **Preferences** > **Global**, and set it in the **Default Internet browser** field.

- **Output file** - When **Open in Browser/System Application** is selected, you can use this button to automatically open the default output file at the end of the transformation.
- **Other location** - When **Open in Browser/System Application** is selected, you can use this option to open the file specified in this field at the end of the transformation. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Open in editor

When this is option is selected, at the end of the transformation, the default output file is opened in a new editor panel with the appropriate built-in editor type (for example, if the result is an XML file it is opened in the built-in XML editor, or if it is an XSL-FO file it is opened with the built-in FO editor).

Show in results view as

You can choose to view the results in one of the following:

- **XML** - If this is selected, Oxygen XML Editor displays the transformation result in an XML viewer panel at the bottom of the application window with *syntax highlighting*.
- **SVG** - If this is selected, Oxygen XML Editor displays the transformation result in an *integrated SVG viewer in the **Results** panel* at the bottom of the application window and renders the result as an SVG image.
- **XHTML** - This option is only available if **Open in Browser/System Application** is not selected. If selected, Oxygen XML Editor displays the transformation result in a built-in XHTML browser panel at the bottom of the application window.

  Important: When transforming very large documents, you should be aware that selecting this option may result in very long processing times. This drawback is due to the built-in Java XHTML browser implementation. To avoid delays for large documents, if you want to see the XHTML result of the transformation, you should use an external browser by selecting the **Open in Browser/System Application** option instead.

  - **Image URLs are relative to** - If **Show in results view as XHTML** is selected, this option specifies the path used to resolve image paths contained in the transformation result. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

SQL Transformation

This type of transformation specifies a database connection for the database server that runs the SQL file associated with the scenario. The data processed by the SQL script is located in the database.

To create an **SQL transformation** scenario, use one of the following methods:

- Use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu. Then click the **New** button and select **SQL transformation**.

- Go to **Window** > **Show View** and select **Transformation Scenarios** to display *this view*. Click the **New Scenario** drop-down menu button and select **SQL transformation**.

Both methods open the **New Scenario** dialog box. This dialog box allows you to configure the following options that control the transformation:

Name

The unique name of the SQL transformation scenario.

Storage

Allows you to select one of the following storage options:

- ***Project Options*** - The scenario is stored in the project file and can be shared with other users. For example, if your project is saved on a source versioning/sharing system (CVS, SVN, Source Safe, etc.) or a shared folder, your team can use the scenarios that you store in the project file.
- ***Global Options*** - The scenario is saved in the global options that are stored in the user home directory and is not accessible to other users.

SQL URL

Allows you to specify the URL of the SQL script. You can specify the path by using the text field, its history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list. You can also use the **Open in editor** button to open the specified file in the editor panel.

Connection

Allows you to select a connection from a drop-down list. To configure a connection, use the **Advanced options** button to open the ***Data Source*** *preferences page*.

Parameters

Allows you to add or configure parameters for the transformation.

Editing a Transformation Scenario

Editing a transformation scenario is useful if you need to configure some of its parameters.

Note: Since transformation scenarios that are associated with predefined *frameworks* are read-only, to edit one of these scenarios you will need to *duplicate it and edit the duplicated scenario*.

To configure an existing transformation scenario, follow these steps:

1. Select the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.

   Step Result: The ***Configure Transformation Scenario(s)*** *dialog box* is opened.
2. Select the particular transformation scenario and click the **Edit** button at the bottom of the dialog box or from the contextual menu.

   Tip: You could also select the scenario and the **Edit** button in the ***Transformation Scenarios*** *view* to achieve the same result.

Result: This will open an **Edit scenario** configuration dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected.

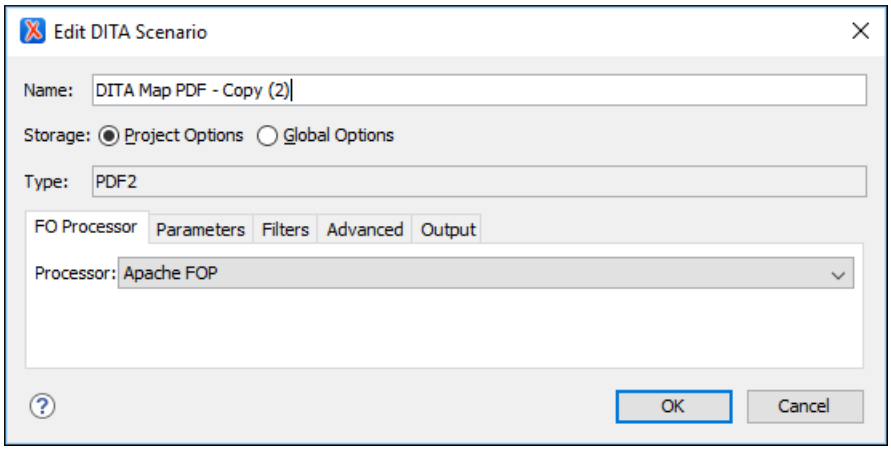

Figure 615: Edit Scenarios Configuration Dialog Box

Transformation Types

The ***Configure Transformation Scenario(s)*** *dialog box* contains a **Type** column that shows you the transformation type for each of the listed scenarios. Each type of transformation contains includes some tabs with various configuration options.

The following is a list of the transformation types and their particular tabs (click the name of each tab below to see details about all the options that are available):

- **DITA OT** - This type of transformation includes configurable options in the following tabs:
  - *Skins Tab* (Available for **WebHelp Classic** and **WebHelp Classic with Feedback**)
  - *Templates Tab* (Available for **WebHelp Responsive** and **WebHelp Responsive with Feedback**)
  - *FO Processor Tab* (Available for PDF output)
  - *Parameters Tab*
  - *Filters Tab*
  - *Advanced Tab*
  - *Output Tab*
- **ANT** - This type of transformation includes configurable options in the following tabs:
  - *Options Tab*
  - *Parameters Tab*
  - *Output Tab*
- **XSLT** - This type of transformation includes configurable options in the following tabs:
  - *XSLT Tab*
  - *FO Processor Tab*
  - *Output Tab*
- **XProc** - This type of transformation includes configurable options in the following tabs:
  - *XProc Tab*
  - *Inputs Tab*
  - *Parameters Tab*
  - *Outputs Tab*
  - *Options Tab*
- **XQuery** - This type of transformation includes configurable options in the following tabs:
  - *XQuery Tab*
  - *FO Processor Tab*
  - *Output Tab*

Configure Transformation Scenario(s) Dialog Box on page 1138
Apply Associated Transformation Scenarios on page 1141

Duplicating a Transformation Scenario

Duplicating a transformation scenario is useful for creating a scenario that is similar to an existing one or to edit a predefined transformation scenario.

To configure an existing transformation scenario, follow these steps:

1. Select the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.

   Step Result: The ***Configure Transformation Scenario(s)*** *dialog box* is opened.
2. Select the particular transformation scenario and click the **Duplicate** button at the bottom of the dialog box or from the contextual menu.

   Tip: You could also select the scenario and the **Duplicate** button in the ***Transformation Scenarios*** *view* to achieve the same result.

Result: This will open an **Edit scenario** configuration dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected. For information about all the specific options in the various tabs, see the *Transformation Types section*.

Configure Transformation Scenario(s) Dialog Box

You can use the **Configure Transformation Scenarios(s)** dialog box for *editing exiting transformation scenarios* or *creating new ones*.

To open this dialog box, use the **Configure Transformation Scenario(s) (Ctrl + Shift + C (Command + Shift + C on OS X))** action from the toolbar or the **Document** > **Transformation** menu.

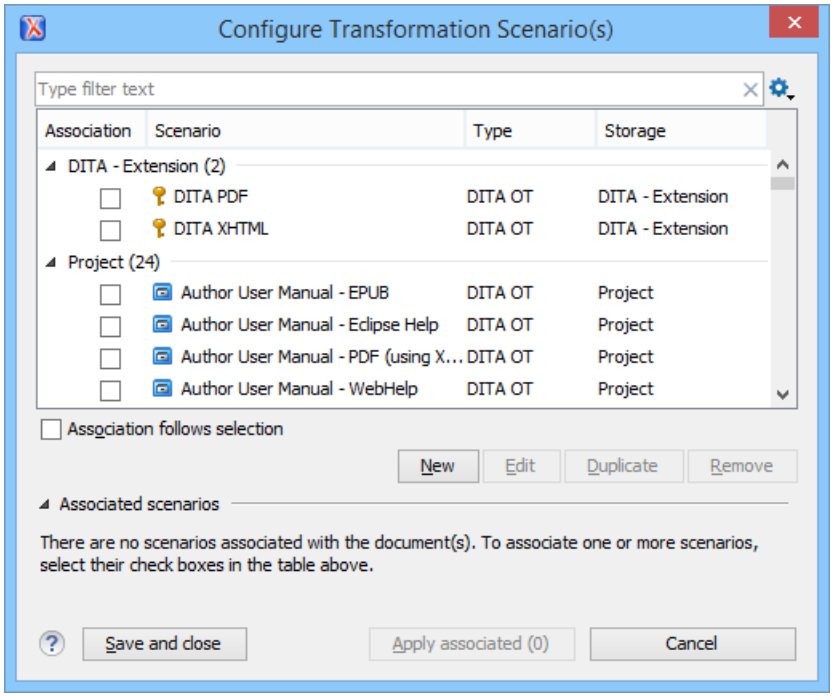

Figure 616: Configure Transformation Scenario(s) Dialog Box

Top Section

The top section of the dialog box contains a filter that allows you to search through the scenarios list and the **Settings** button allows you to configure the following options:

Show all scenarios

Select this option to display all the available scenarios, regardless of the document they are associated with.

Show only the scenarios available for the editor

Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

Show associated scenarios

Select this option to only display the scenarios associated with the document you are editing.

Import scenarios

This option opens the **Import scenarios** dialog box that allows you to select the `scenarios` file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

  Note: When you keep both scenarios, Oxygen XML Editor adds `imported` to the name of the imported scenario.

Export selected scenarios

Use this option to export selected scenarios individually. Oxygen XML Editor creates a `scenarios` file that contains the scenarios that you export. This is useful if you want to share scenarios with others or export them to another computer.

Middle Section

The middle section of the dialog box displays the scenarios that you can apply to the current document. You can view both the scenarios associated with the current document type and the scenarios defined at *project level*. The following columns are used to display the transformation scenarios:

- **Association** - The checkboxes in this column mark whether or not a transformation scenario is associated with the current document.
- **Scenario** - This column presents the names of the transformation scenarios.
- **Type** - If the **Show Type** contextual menu option is selected, this column displays the type of the transformation scenario. For further details about the types of transformation scenarios that are available in Oxygen XML Editor, see the *Transformation Types section*.
- **Storage** - If the **Show Storage** contextual menu option is selected, this column displays where a transformation scenario is stored.

To sort each column you can left-click its header. The contextual menu of each header also includes the following actions:

Show Type

Use this option to display the transformation type of each scenario.

Show Storage

Use this option to display the storage location of the scenarios.

Group by Association

Select this option to group the scenarios depending on whether or not they are associated with the current document.

Group by Type

Select this option to group the scenarios by their type.

Group by Storage

Select this option to group the scenarios by their storage location.

Ungroup all

Select this option to ungroup all the scenarios.

Reset Layout

Select this option to restore the default settings of the layout.

Each transformation scenarios listed in the middle section of the dialog box also includes the following contextual menu actions:

Edit

This button opens the ***Edit Scenario*** *configuration dialog box* that allows you to configure the options of the transformations scenario.

Duplicate

Use this button to create a *duplicate transformation scenario*.

Remove

Use this button to remove custom transformation scenarios.

Change storage

Allows you to change the storage location of a transformation scenario to ***Project Options*** or ***Global Options***. You are also able to keep the original storage location and make a copy of the selected scenario in the new storage location.

Import scenarios

This option opens the **Import scenarios** dialog box that allows you to select the `scenarios` file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

  Note: When you keep both scenarios, Oxygen XML Editor adds `imported` to the name of the imported scenario.

Export selected scenarios

Use this option to export selected scenarios individually. Oxygen XML Editor creates a `scenarios` file that contains the scenarios that you export. This is useful if you want to share scenarios with others or export them to another computer.

Bottom Section

The bottom section of the dialog box contains the following actions and information:

Association follows selection

Select this checkbox to automatically associate selected transformation scenarios with the current document. This option can also be used for multiple selections.

Note: When this option is selected, the **Association** column is hidden.

New

This button allows you to *create a new transformation scenario*.

Edit

This button opens the **Edit Scenario** dialog box that allows you to configure the options of the transformations scenario. For information about all the specific options in the various tabs, see the *Transformation Types section*.

Note: If you try to edit a transformation scenario associated with a defined document type, Oxygen XML Editor displays a warning message to inform you that this is not possible and gives you the option to create a *duplicate transformation scenario* to edit instead.

Duplicate

Use this button to create a *duplicate transformation scenario*.

Remove

Use this button to remove transformation scenarios.

Note: Removing scenarios associated with a defined document type is not allowed.

Associated scenarios section

Displays the scenarios that are associated with the current document. Selecting a checkbox in the ***Association** column* in the list of scenarios will add that scenario to this section. To remove a scenario from being associated with the current document, simply click the remove icon () to the right of the scenario name.

Save and close

Saves the current configuration and closes the dialog box.

Apply associated

Use this button to apply the associated scenarios and run the transformation on the current document.

Cancel

Cancels any changes made in the dialog box and reverts to the previously saved association.

Your selections in the **Configure Transformation Scenarios(s)** dialog box are persistent so the configured associations for the current document will be remembered after the dialog box is closed.

Related Information:

Editing a Transformation Scenario on page 1136

Apply Associated Transformation Scenarios on page 1141
Creating New Transformation Scenarios on page 1099
Sharing Transformation Scenarios on page 1142

Apply Associated Transformation Scenarios

If you have associated transformation scenarios for the current document (in the ***Configure Transformation Scenario(s)** dialog box* or ***Transformation Scenarios** view*), Oxygen XML Editor included an **Apply Transformation Scenario(s)** action that allows you to quickly apply the associated transformation scenarios on the current document. Note that if an association is not detected, this action will open the ***Configure Transformation Scenario(s)** dialog box* where you can choose the scenarios you want to apply.

The **Apply Transformation Scenario(s)** action can be initiated from any of the following methods:

- Use the **Ctrl + Shift + T (Command + Shift + T on OS X))** keyboard shortcut.
- Click the **Apply Transformation Scenario(s)** button on the main toolbar.
- Click the **Apply Transformation Scenario(s)** button on the toolbar in the ***Transformation Scenarios** view*.
- Right-click a file in the ***Project** view* and select **Transform** > **Apply Transformation Scenario(s)**.
- Use the **Apply Associated** button in the ***Configure Transformation Scenario(s)** dialog box*.

Related Information:

Creating New Transformation Scenarios on page 1099
Editing a Transformation Scenario on page 1136
Configure Transformation Scenario(s) Dialog Box on page 1138
Transformation Scenarios View on page 1143

Apply Batch Transformations

A transformation action can be applied on a batch of selected files *from the contextual menu of the **Project** view* without having to open the files involved in the transformation. You can apply the same scenario to a batch of files or multiple scenarios to a single file or batch of files.

1. (Optional, but recommended) Organize the files you want to transform in logical folders.
   a) Create a logical folder in the ***Project** view* by using the **New** > **Logical Folder** action from the contextual menu of the root file.
   b) Add files you want to transform to the logical folder by using the **Add Files** or **Add Edited File** actions from the contextual menu of the logical folder.

      Note: You can skip this step if the files are already in a dedicated folder that does not include any additional files or folders. You can also manually select the individual files in the ***Project** view* each time you want to transform them, but this can be tedious.
2. Select the files you want to transform (or the newly created logical folder) and from the contextual menu, select **Transform** > **Configure Transformation Scenario(s)** to choose one or more transformation scenarios to be applied on all the files in the logical folder.
3. Use Oxygen XML Editor *editor variables* to specify the input and output files. This ensures that each file from the selected set of resources is processed and that the output is not overwritten by the subsequent processing.
   a) Edit the transformation scenario to make sure the appropriate *editor variable* is assigned for the input file. For example, for a *DocBook PDF transformation* make sure the **XML URL** input box is set to the *${currentFileURL} editor variable*. For a DITA PDF transformation make sure the `args.input` parameter is set to the *${cf} editor variable*.
   b) Edit the transformation scenario to make sure the appropriate editor variable is assigned for the output file. For example, for an **XML transformation with XSLT**, switch to the **Output** tab and set the path of the output file using a construct of *editor variables*, such as `${cfd}/${cfn}.html`.
4. Now that logical folder has been associated with one or more transformation scenarios, whenever you want to apply the same batch transformation you can select **Transform** > **Transform with** from the contextual menu and the same previously associated scenario(s) will be applied.
5. If you want a different type of transformation to be applied to each file inside the logical folder, associate individual scenarios for each file and select **Transform** > **Apply Transformation Scenario(s)** from the contextual menu of the logical folder.

Related Information:

Editor Variables on page 173

Sharing Transformation Scenarios

The transformation scenarios and their settings can be shared with other users by saving them at *project level* or by *exporting them to a specialized scenarios file* that can then be imported. When you create a new transformation scenario or edit an existing one, there is a **Storage** option to control whether the scenarios are stored in ***Project Options*** or ***Global Options***.

Selecting ***Project Options*** stores the scenario in the project file and can be shared with other users that have access to the project. If your project is saved on a source versioning system (CVS, SVN, Source Safe, etc.) then your team will have access to the scenarios that you define. When you create a scenario at the project level, the URLs from the scenario become relative to the project URL.

Selecting ***Global Options*** stores the scenario in the global options that are stored in the user home directory.

You can also change the storage options on existing transformation scenarios by using the ***Change storage** action* from the contextual menu of the list of scenarios.

Related Information:

Sharing Application Settings on page 166

Transformation Scenarios View

You can manage the transformation scenarios by using the **Transformation Scenarios** view. To open this view, select **Window** > **Show View** > **Transformation Scenarios**.

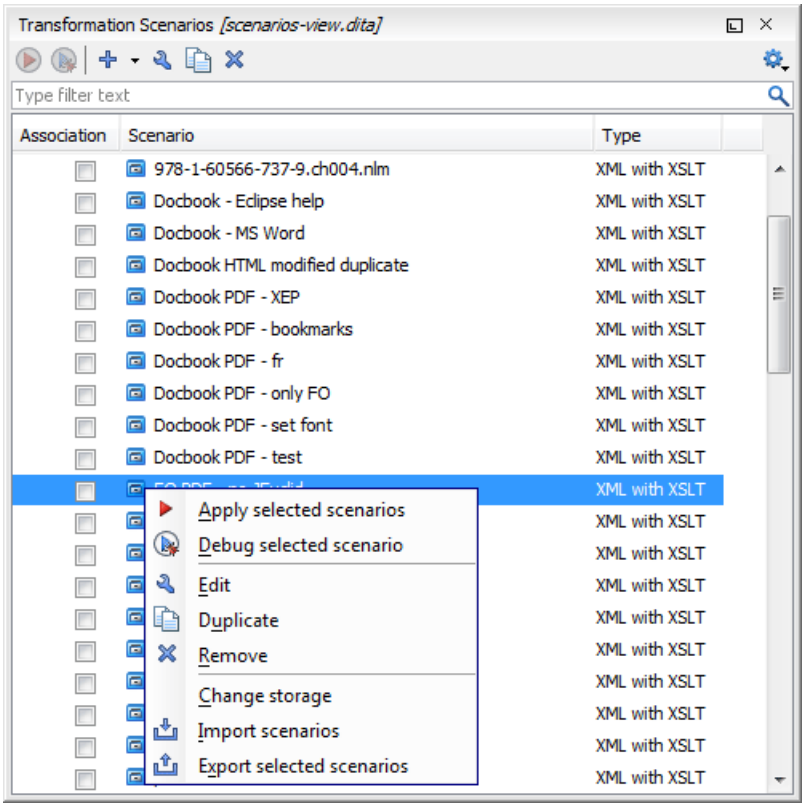

Figure 617: Transformation Scenarios view

Oxygen XML Editor supports multiple scenarios association. To associate multiple scenarios with a document, select the checkboxes in front of each scenario. You can also associate multiple scenarios with a document from the ***Configure Transformation Scenario(s)*** *dialog box*.

The **Transformation Scenarios** view presents both global and *project-level* scenarios. By default, Oxygen XML Editor presents the items in the following order:

1. Scenarios that match the current *framework*.
2. Scenarios that match the current project.
3. Scenarios that match other *frameworks*.

Toolbar/Contextual Menu Actions and Options

The following actions and options are available on the toolbar or in the contextual menu:

Apply selected scenarios

Select this option to run the current transformation scenario.

Debug selected scenario

Select this option to switch to the **Debugger** *perspective* and initialize it with the parameters from the scenario (the XML, XSLT, or XQuery input, the transformation engine, the XSLT parameters).

New

This drop-down menu contains a list of the *scenarios that you can create*. Oxygen XML Editor determines the most appropriate scenarios for the current type of file and displays them at the beginning of the list, followed by the rest of the scenarios.

Duplicate

Adds a new scenario to the list that is a duplicate of the current scenario. It is useful for creating a scenario that is similar to an existing one.

Edit

Opens the dialog box that allows you to configure various options in several tabs, depending on the type of transformation scenario that was selected. For information about all the specific options in the various tabs, see the *Transformation Types section*.

Remove

Removes the current scenario from the list. This action is also available by using the **Delete** key.

Change storage

Use this option to change the storage location of the selected scenario. You are also able to keep the original storage location and make a copy of the selected scenario in the target storage location.

Import scenarios

This option opens the **Import scenarios** dialog box that allows you to select the `scenarios` file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

  Note: When you keep both scenarios, Oxygen XML Editor adds `imported` to the name of the imported scenario.

Export selected scenarios

Use this option to export transformation and validation scenarios individually. Oxygen XML Editor creates a `scenarios` file that contains the scenarios that you export.

Settings

This drop-down menu allows you to configure the following options (many of these options are also available if you right-click the name of a column):

Show all scenarios

Select this option to display all the available scenarios, regardless of the document they are associated with.

Show only the scenarios available for the editor

Select this option to only display the scenarios that Oxygen XML Editor can apply for the current document type.

Show associated scenarios

Select this option to only display the scenarios associated with the document you are editing.

Change storage

Use this option to change the storage location of the selected scenario to ***Project Options*** or ***Global Options***. You are also able to keep the original storage location and make a copy of the selected scenario in the new storage location.

Import scenarios

This option opens the **Import scenarios** dialog box that allows you to select the `scenarios` file that contains the scenarios you want to import. If one of the scenarios you import is identical to an existing scenario, Oxygen XML Editor ignores it. If a conflict appears (an imported scenario has the same name as an existing one), you can choose between two options:

- Keep or replace the existing scenario.
- Keep both scenarios.

Note: When you keep both scenarios, Oxygen XML Editor adds `imported` to the name of the imported scenario.

Export selected scenarios

Use this option to export selected scenarios individually. Oxygen XML Editor creates a `scenarios` file that contains the scenarios that you export. This is useful if you want to share scenarios with others or export them to another computer.

Show Type

Use this option to display the transformation type of each scenario.

Show Storage

Use this option to display the storage location of the scenarios.

Group by Association

Select this option to group the scenarios depending on whether or not they are associated with the current document.

Group by Type

Select this option to group the scenarios by their type.

Group by Storage

Select this option to group the scenarios by their storage location.

Ungroup all

Select this option to ungroup all the scenarios.

Reset Layout

Select this option to restore the default settings of the layout.

Your selections in the **Transformation Scenarios** view are persistent so the configured associations for the current document will be remembered whenever the document is opened.

Related Information:

Editing a Transformation Scenario on page 1136
Creating New Transformation Scenarios on page 1099

Debugging PDF Transformations

To debug a DITA PDF transformation scenario using the XSLT Debugger follow these steps:

1. *Open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **XML** > **XML Catalog**, click **Add**, and select the file located at *DITA-OT-DIR*`\plugins\org.dita.pdf2\cfg\catalog.xml`.
2. Open the map in the ***DITA Maps Manager*** and create a **DITA Map PDF** transformation scenario.
3. Edit the scenario, go to the **Parameters** tab and change the value of the **clean.temp** parameter to **no**.
4. Run the transformation scenario.
5. Open the **stage1.xml** file located in the temporary directory and *format and indent* it.
6. Create a transformation scenario for this XML file by associating the `topic2fo_shell_fop.xsl` stylesheet located at *DITA-OT-DIR*`\plugins\org.dita.pdf2\xsl\fo\topic2fo_shell_fop.xsl`. If you are specifically using the RenderX XEP or Antenna House FO processors to build the PDF output, you should use the XSL stylesheets `topic2fo_shell_xep.xsl` or `topic2fo_shell_axf.xsl` located in the same folder.
7. In the transformation scenario edit the XSLT Processor combo box choose the Saxon EE XSLT processor (the same processor used when the DITA OT transformation is executed).
8. In the transformation scenario, edit the **Parameters** list and set the parameter `locale` with the value `en_GB` and the parameter `customizationDir.url` to point either to your customization directory or to the default DITA OT customization directory. Its value should have a URL syntax like this: `file://c:/path/to/`*DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg`.
9. Debug the transformation scenario.

Related Information:

Debugging XSLT Stylesheets and XQuery Documents on page 1357

Configuring Calabash with XEP

To generate PDF output from your XProc pipeline (when using the Calabash XProc processor), follow these steps:

1. Open the *[OXYGEN_INSTALL_DIR]*`/lib/xproc/calabash/engine.xml` file.
2. Uncomment the `<system-property name="com.xmlcalabash.fo-processor" value="com.xmlcalabash.util.FoXEP"/>` system property.
3. Uncomment the `<system-property name="com.renderx.xep.CONFIG" file="../../../tools/xep/xep.xml"/>` system property. Edit the `file` attribute to point to the configuration file that is usually located in the XEP installation folder.
4. Uncomment the references to the XEP libraries. Edit them to point to the matching library names from the XEP installation directory.
5. Restart Oxygen XML Editor.

Integration of an External XProc Engine

The Javadoc documentation of the XProc API is available for download from the application website as a zip file: *xprocAPI.zip*.

To create an XProc integration project, follow these steps:

1. Move the `oxygen.jar` file from *[OXYGEN_INSTALL_DIR]*`/lib` to the `lib` folder of your project.
2. Implement the *ro.sync.xml.transformer.xproc.api.XProcTransformerInterface* interface.
3. Create a *Java archive (JAR)* from the classes you created.
4. Create a `engine.xml` file according with the `engine.dtd` file. The attributes of the `engine` element are as follows:
   1. **name** - The name of the XProc engine.
   2. **description** - A short description of the XProc engine.
   3. **class** - The complete name of the class that implements *ro.sync.xml.transformer.xproc.api.XProcTransformerInterface*.
   4. **version** - The version of the integration.
   5. **engineVersion** - The version of the integrated engine.
   6. **vendor** - The name of the vendor / implementer.
   7. **supportsValidation** - **true** if the engine supports validation (otherwise, **false**).

   The `engine` element has only one child, `runtime`. The `runtime` element contains several `library` elements with the `name` attribute containing the relative or absolute location of the libraries necessary to run this integration.
5. Create a folder with the name of the integration in the *[OXYGEN_INSTALL_DIR]*`/lib/xproc`.
6. Place the `engine.xml` and all the libraries necessary to run the new integration in that folder.

XSLT Processors

This section explains how to configure an XSLT processor and extensions for such a processor in Oxygen XML Editor.

Supported XSLT Processors

Oxygen XML Editor includes the following XSLT processors:

- **Xalan 2.7.1** - *Xalan-Java* is an XSLT processor for transforming XML documents into HTML, text, or other XML document types. It implements XSL Transformations (XSLT) Version 1.0 and XML Path Language (XPath) Version 1.0.
- **Saxon 6.5.5** - *Saxon 6.5.5* is an XSLT processor that implements the Version 1.0 XSLT and XPath with a number of powerful extensions. This version of Saxon also includes many of the new features that were first defined in the XSLT 1.1 working draft, but for conformance and portability reasons these are not available if the stylesheet header specifies `version="1.0"`.
- **Saxon 9.7.0.19 Home Edition (HE), Professional Edition (PE)** - *Saxon-HE/PE* implements the basic conformance level for XSLT 2.0 / 3.0 and XQuery 1.0. The term *basic XSLT 2.0 / 3.0 processor* is defined in

the draft XSLT 2.0 / 3.0 specifications. It is a conformance level that requires support for all features of the language other than those that involve schema processing. The HE product remains open source, but removes some of the more advanced features that are present in Saxon-PE.

- **Saxon 9.7.0.19 Enterprise Edition (EE)** - *Saxon EE* is the schema-aware edition of Saxon and it is one of the built-in processors included in Oxygen XML Editor. Saxon EE includes an XML Schema processor, and schema-aware XSLT, XQuery, and XPath processors.

  The validation in schema aware transformations is done according to the W3C XML Schema 1.0 or 1.1. This can be *configured in Preferences*.

  Note: Oxygen XML Editor implements a Saxon *framework* that allows you to create Saxon configuration files. Two templates are available: **Saxon collection catalog** and **Saxon configuration**. Both of these templates support content completion, element annotation, and attribute annotation.

  Note: Saxon can use the *ICU-J localization library* (`saxon9-icu.jar`) to add support for sorting and date/number formatting in a wide variety of languages. This library is not included in the Oxygen XML Editor installation kit. However, Saxon will use the default collation and localization support available in the currently used JRE. To enable this capability, follow these steps:

  1. Download Saxon 9.7.0.19 Professional Edition (PE) or Enterprise Edition (EE) from *http://www.saxonica.com*.
  2. Unpack the downloaded archive.
  3. Create a new XSLT transformation scenario (or edit an existing one). In the **XSLT** tab, click the **Extensions** button to open the list of additional libraries used by the transformation process.
  4. Click **Add** and browse to the folder where you unpacked the downloaded archive and choose the `saxon9-icu.jar` file.

  Note that the `saxon9-icu.jar` should NOT be added to the application library folder because it will conflict with another version of the ICU-J library that comes bundled with Oxygen XML Editor.
- **Saxon-CE (Client Edition)** is Saxonica's implementation of XSLT 2.0 for use on web browsers. Oxygen XML Editor provides support for editing stylesheets that contain Saxon-CE extension functions and instructions. This support improves the validation, content completion, and syntax highlighting.

  Note: Saxon-CE, being JavaScript-based, was designed to run inside a web browser. This means that you will use Oxygen XML Editor only for developing the Saxon-CE stylesheet, leaving the execution part to a web browser. See more details about *executing such a stylesheet on Saxonica's website*.

  Note: A specific template, named **Saxon-CE stylesheet**, is available in the ***New** document wizard*.
- **Xsltproc (libxslt)** - *Libxslt* is the XSLT C library developed for the Gnome project. **Libxslt** is based on *libxml2*, the XML C library developed for the Gnome project. It also implements most of the EXSLT set of processor-portable extensions, functions, and some of Saxon's evaluate and expression extensions. The *libxml2* version included in Oxygen XML Editor is 2.7.6 and the **Libxslt** version is 1.1.26.

  Oxygen XML Editor uses **Libxslt** through its command line tool (*Xsltproc*). The XSLT processor is included in the distribution kit of the stand-alone version for Windows and Mac OS X. Since there are differences between various Linux distributions, on Linux you must install **Libxslt** on your machine as a separate application and set the PATH variable to contain the **Xsltproc** executable.

  Note: The Xsltproc processor can be configured from the ***XSLTPROC** options page*.

  CAUTION: There is a known problem where file paths that contain spaces are not handled correctly in the LIBXML processor. For example, the built-in *XML Catalog* files of the predefined document types (DocBook, TEI, DITA, etc.) are not handled properly by LIBXML if Oxygen XML Editor is installed in the default location on Windows (C:\Program Files). This is because the built-in *XML catalog* files are stored in the *[OXYGEN_INSTALL_DIR]*`/frameworks` subdirectory of the installation directory, and in this case it contains a space character.
- **MSXML 4.0** - *MSXML 4.0* is available only on Windows platforms. It can be used for *transformation* and *validation of XSLT stylesheets*.

  Oxygen XML Editor uses the Microsoft XML parser through its command line tool *msxsl.exe*.

  Since `msxsl.exe` is only a wrapper, Microsoft Core XML Services (MSXML) must be installed on the computer. Otherwise, you will get a corresponding warning. You can get the latest Microsoft XML parser from *Microsoft web-site*.

- **MSXML .NET** - *MSXML .NET* is available only on Windows platforms. It can be used for *transformation* and *validation of XSLT stylesheets*.

  Oxygen XML Editor performs XSLT transformations and validations using the .NET *Framework* XSLT implementation (*System.Xml.Xsl.XslTransform* class) through the **nxslt** command line utility. The **nxslt** version included in Oxygen XML Editor is 1.6.

  You should have the .NET *Framework* version 1.0 already installed on your system. Otherwise, you will get the following warning: `MSXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128`.

  You can get the .NET *Framework* version 1.0 from the *Microsoft website*.
- **.NET 1.0** - A transformer based on the **System.Xml** 1.0 library available in the .NET 1.0 and .NET 1.1 *frameworks* from Microsoft (*http://msdn.microsoft.com/xml/*). It is available only on Windows.

  You should have the .NET *Framework* version 1.0 or 1.1 already installed on your system. Otherwise, you will get the following warning: `MSXML.NET requires .NET Framework version 1.0 to be installed. Exit code: 128`.

  You can get the .NET *Framework* version 1.0 from the *Microsoft website*.
- **.NET 2.0** - A transformer based on the **System.Xml** 2.0 library available in the .NET 2.0 *Framework* from *Microsoft*. It is available only on Windows.

  You should have the .NET *Framework* version 2.0 already installed on your system. Otherwise, you will get the following warning: `MSXML.NET requires .NET Framework version 2.0 to be installed. Exit code: 128`.

  You can get the .NET *Framework* version 2.0 from the *Microsoft website*.

For information about configuring the XSLT preferences, see the *XSLT options* section.

Configuring Custom XSLT Processors

Oxygen XML Editor allows you to configure custom processors to be used for running XSLT and XQuery transformations.

To add a new custom processor, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **XML** > **XSLT-FO-XQuery** > **Custom Engines**.
2. Click the **New** button at the bottom of the dialog box.
3. Configure the *parameters for the custom engine*.
4. Click **OK**.

Note: You can not use these custom engines in *the Debugger perspective*.

The output messages of a custom processor are displayed in an output view at the bottom of the application window. If an output message follows *the format of an Oxygen XML Editor linked message*, clicking it highlights the location of the message in an editor panel containing the file referenced in the message.

Related Information:

Custom Engines Preferences on page 134

Configuring the XSLT Processor Extensions Paths

The Xalan and Saxon processors support the use of extension elements and extension functions. Unlike a literal result element, which the stylesheet simply transfers to the result tree, an extension element performs an action. The extension is usually used because the XSLT stylesheet fails in providing adequate functions for accomplishing a more complex task.

For more information about how to use extensions, see the following links:

- **Xalan** - *http://xml.apache.org/xalan-j/extensions.html*
- **Saxon 6.5.5** - *http://saxon.sourceforge.net/saxon6.5.5/extensions.html*
- **Saxon 9.7.0.19** - *http://www.saxonica.com/documentation9.5/index.html#!extensibility*

To set an XSLT processor extension (a directory or a `jar` file), use *the **Extensions** button* in the **Edit scenario** dialog box.

XSL-FO Processors

This section explains how to apply XSL-FO processors when transforming XML documents to various output formats in Oxygen XML Editor.

Built-in XSL-FO Processor

The Oxygen XML Editor installation package is distributed with the *Apache FOP* that is a Formatting Objects processor for rendering your XML documents to PDF. *FOP* is a print and output independent formatter driven by XSL Formatting Objects. *FOP* is implemented as a Java application that reads a formatting object tree and renders the resulting pages to a specified output.

To see the version of the built-in XSL-FO processor for your installation, go to **Help** > **About** > **Libraries** and search for *Apache FOP*.

Other FO processors can be configured in *the **Preferences** dialog box*.

Add a Font to the Built-in FO Processor - Simple Version

If the font that must be set to Apache FOP is one of the fonts that are installed in the operating system you should follow the next steps for creating and setting a FOP configuration file that looks for the font that it needs in the system fonts. It is a simplified version of *the procedure for setting a custom font in Apache FOP*.

1. Register the font in FOP configuration. (This is not necessary for DITA PDF transformations, skip to the next step)
   a) Create a FOP configuration file that specifies that FOP should look for fonts in the installed fonts of the operating system.

```
<fop version="1.0">
  <renderers>
    <renderer mime="application/pdf">
      <fonts>
        <auto-detect/>
      </fonts>
    </renderer>
  </renderers>
</fop>
```

   b) *Open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **XML** > **XSLT/FO/XQuery** > **FO Processors**, and enter the path of the FOP configuration file in the **Configuration file** text field.
2. Set the font on the document content.

   This is done usually with XSLT stylesheet parameters and depends on the document type processed by the stylesheet.

   - For DocBook documents you can start with the predefined scenario called **DocBook PDF**, *edit the XSLT parameters* and set the font name (in our example the font family name is **Arial Unicode MS**) to the parameters body.font.family and title.font.family.
   - For TEI documents you can start with the predefined scenario called **TEI PDF**, *edit the XSLT parameters* and set the font name (in our example **Arial Unicode MS**) to the parameters bodyFont and sansFont.
   - For DITA transformations to PDF using DITA-OT you should modify the following two files:
     - *DITA-OT-DIR*`/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml` - The `font-face` element included in each element `physical-font` having the `attribute char-set="default"` must contain the name of the font (**Arial Unicode MS** in our example)
     - *DITA-OT-DIR*`/plugins/org.dita.pdf2/fop/conf/fop.xconf` - An element `auto-detect` must be inserted in the element `fonts`, which is inside the element `renderer` that has the attribute `mime="application/pdf"`:

```
<renderer mime="application/pdf">
  . . .
   <fonts>
       <auto-detect/>
   </fonts>
  . . .
</renderer>
```

Add a Font to the Built-in FO Processor

If an XML document is transformed to PDF using the built-in Apache FOP processor but it contains some Unicode characters that cannot be rendered by the default PDF fonts, then a special font that is capable to render these characters must be configured and embedded in the PDF result.

Important: If this special font is installed in the operating system, there is a simple way of telling FOP to look for it. See *the simplified procedure for adding a font to FOP*.

1. Locate the font.

   First, find out the name of a font that has the glyphs for the special characters you used. One font that covers most characters, including Japanese, Cyrillic, and Greek, is Arial Unicode MS.

   On Windows the fonts are located into the `C:\Windows\Fonts` directory. On Mac, they are placed in `/Library/Fonts`. To install a new font on your system, is enough to copy it in the `Fonts` directory.
2. Generate a font metrics file from the font file.
   a) Open a terminal.
   b) Change the working directory to the Oxygen XML Editor install directory.
   c) Create the following script file in the Oxygen XML Editor installation directory.

      For OS X and Linux create a file `ttfConvert.sh`:

      ```
      #!/bin/sh

      export LIB=lib
      export CP=$LIB/fop.jar
      export CP=$CP:$LIB/avalon-framework-4.2.0.jar
      export CP=$CP:$LIB/xercesImpl.jar
      export CP=$CP:$LIB/commons-logging-1.1.3.jar
      export CP=$CP:$LIB/commons-io-1.3.1.jar
      export CP=$CP:$LIB/xmlgraphics-commons-1.5.jar
      export CP=$CP:$LIB/xml-apis.jar
      export CMD="java -cp $CP org.apache.fop.fonts.apps.TTFReader"
      export FONT_DIR='.'

      $CMD $FONT_DIR/Arialuni.ttf Arialuni.xml
      ```

      For Windows create a file `ttfConvert.bat`:

      ```
      @echo off
      set LIB=lib
      set CP=%LIB%\fop.jar
      set CP=%CP%;%LIB%\avalon-framework-4.2.0.jar
      set CP=%CP%;%LIB%\xercesImpl.jar
      set CP=%CP%;%LIB%\commons-logging-1.1.3.jar
      set CP=%CP%;%LIB%\commons-io-1.3.1.jar
      set CP=%CP%;%LIB%\xmlgraphics-commons-1.5.jar
      set CP=%CP%;%LIB%\xml-apis.jar
      set CMD=java -cp "%CP%" org.apache.fop.fonts.apps.TTFReader
      set FONT_DIR=C:\Windows\Fonts
      %CMD% %FONT_DIR%\Arialuni.ttf Arialuni.xml
      ```

      The paths specified in the file are relative to the Oxygen XML Editor installation directory. If you decide to create it in other directory, change the file paths accordingly.

      The `FONT_DIR` can be something different on your system. Check that it points to the correct font directory. If the Java executable is not in the `PATH`, specify the full path of the executable.

      If the font has bold and italic variants, convert them too by adding two more lines to the script file:

      - for OS X and Linux:

        ```
        $CMD $FONT_DIR/Arialuni-Bold.ttf Arialuni-Bold.xml
        $CMD $FONT_DIR/Arialuni-Italic.ttf Arialuni-Italic.xml
        ```

      - for Windows:

        ```
        %CMD% %FONT_DIR%\Arialuni-Bold.ttf Arialuni-Bold.xml
        %CMD% %FONT_DIR%\Arialuni-Italic.ttf Arialuni-Italic.xml
        ```

   d) Run the script.

      On Linux and OS X, run the command `sh ttfConvert.sh` from the command line. On Windows, run the command `ttfConvert.bat` from the command line or double-click the file `ttfConvert.bat`.

3. Register the font in FOP configuration. (This is not necessary for DITA PDF transformations, skip to the next step)
   a) Create a FOP configuration file that specifies the font metrics file for your font.

```
<fop version="1.0">
  <base>./</base>
  <font-base>file:/C:/path/to/FOP/font/metrics/files/</font-base>
  <source-resolution>72</source-resolution>
  <target-resolution>72</target-resolution>
  <default-page-settings height="11in" width="8.26in"/>
  <renderers>
    <renderer mime="application/pdf">
      <filterList>
        <value>flate</value>
      </filterList>
      <fonts>
          <font metrics-url="Arialuni.xml" kerning="yes"
                embed-url="file:/Library/Fonts/Arialuni.ttf">
              <font-triplet name="Arialuni" style="normal"
                    weight="normal"/>
          </font>
      </fonts>
    </renderer>
  </renderers>
</fop>
```

   The `embed-url` attribute points to the font file to be embedded. Specify it using the URL convention. The `metrics-url` attribute points to the font metrics file with a path relative to the `base` element. The triplet refers to the unique combination of name, weight, and style (italic) for each variation of the font. In our case is just one triplet, but if the font had variants, you would have to specify one for each variant. Here is an example for Arial Unicode if it had italic and bold variants:

```
<fop version="1.0">
  ...
    <fonts>
        <font metrics-url="Arialuni.xml" kerning="yes"
              embed-url="file:/Library/Fonts/Arialuni.ttf">
            <font-triplet name="Arialuni" style="normal"
                  weight="normal"/>
        </font>
        <font metrics-url="Arialuni-Bold.xml" kerning="yes"
              embed-url="file:/Library/Fonts/Arialuni-Bold.ttf">
            <font-triplet name="Arialuni" style="normal"
                  weight="bold"/>
        </font>
        <font metrics-url="Arialuni-Italic.xml" kerning="yes"
              embed-url="file:/Library/Fonts/Arialuni-Italic.ttf">
            <font-triplet name="Arialuni" style="italic"
                  weight="normal"/>
        </font>
    </fonts>
  ...
</fop>
```

   More details about the FOP configuration file are available on the FOP website.
   b) *Open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **XML** > **XSLT/FO/XQuery** > **FO Processors**, and enter the path of the FOP configuration file in the **Configuration file** text field.
4. Set the font on the document content.

   This is usually done with XSLT stylesheet parameters and depends on the document type processed by the stylesheet.

   DocBook Example: For DocBook documents, you can start with the predefined scenario called **DocBook PDF**, *edit the XSLT parameters*, and set the font name (in our example **Arialuni**) to the parameters body.font.family and title.font.family.

   TEI Example: For TEI documents, you can start with the predefined scenario called **TEI PDF**, *edit the XSLT parameters*, and set the font name (in our example **Arialuni**) to the parameters bodyFont and sansFont.

   DITA Example: For DITA to PDF transformations using DITA-OT modify the following two files:

   - *`DITA-OT-DIR`*`/plugins/org.dita.pdf2/cfg/fo/font-mappings.xml` - The `font-face` element included in each element `physical-font` having the `attribute char-set="default"` must contain the name of the font (*Arialuni* in our example)

- *DITA-OT-DIR*/plugins/org.dita.pdf2/fop/conf/fop.xconf - An element `font` must be inserted in the element `fonts`, which is inside the element `renderer` that has the attribute `mime="application/pdf"`:

```
<renderer mime="application/pdf">
  . . .
   <fonts>
       <font metrics-url="Arialuni.xml" kerning="yes"
           embed-url="file:/Library/Fonts/Arialuni.ttf">
           <font-triplet name="Arialuni" style="normal"
               weight="normal"/>
       </font>
   </fonts>
  . . .
</renderer>
```

Adding Libraries to the Built-in FO Processor (XML with XSLT and FO)

Adding Hyphenation Support for XML with XSLT Transformation Scenarios

You can extend the functionality of the built-in FO processor by dropping additional libraries in the *[OXYGEN_INSTALL_DIR]*/lib/fop directory.

To add support for hyphenation, follow these steps:

1. Create a folder called `fop` in the *[OXYGEN_INSTALL_DIR]*/lib folder.
2. Download the compiled *JAR* from *OFFO*.
3. Copy the `fop-hyph.jar` file into the *[OXYGEN_INSTALL_DIR]*/lib/fop folder.
4. Restart Oxygen XML Editor.

Adding Support for PDF Images

To add support for PDF images, follow these steps:

1. Create a folder called `fop` in the *[OXYGEN_INSTALL_DIR]*/lib folder.
2. Download the *fop-pdf-images* *JAR* libraries.
3. Copy the libraries into the *[OXYGEN_INSTALL_DIR]*/lib/fop folder.
4. Restart Oxygen XML Editor.

Adding Libraries to the Built-in FO Processor (DITA-OT)

To use additional libraries with the DITA-OT publishing engine, you need to edit the transformation scenario and add the path to the new libraries in the **Libraries** section of the **Advanced** tab.

Adding Hyphenation Support for DITA-OT Transformation Scenarios

1. Download the pre-compiled *JAR* from *OFFO*.
2. Edit the DITA-OT transformation scenario and switch to the **Advanced** tab. Click the **Libraries** button and add the path to the `fop-hyph.jar` library.

Adding Support for PDF Images

1. Download the *fop-pdf-images* *JAR* libraries.
2. Edit the DITA-OT transformation scenario and switch to the **Advanced** tab. Click the **Libraries** button and add the path to the libraries.

WebHelp System Output

Oxygen XML Editor allows you to obtain WebHelp Classic and WebHelp Responsive outputs. This section contains information about the WebHelp system, its variants, and ways to customize it to better fit your specific needs.

Table 69: WebHelp System Feature Matrix

Features	WebHelp System Variants

WebHelp Responsive System

WebHelp is a form of online help that consists of a series of web pages (XHTML format). Its advantages include platform independence, ability to update content continuously, and it can be viewed using a regular web browser. The Oxygen XML Editor WebHelp system includes several variants to suit your specific needs. The **WebHelp Responsive** variant features a very flexible layout, is designed to adapt to any screen size, and is available for DITA document types.

This type of WebHelp system can be generated by using the ***DITA Map WebHelp Responsive*** *transformation scenario*.

Layout

The layout of the **WebHelp Responsive** system is platform independent and is able to adapt to any screen size. It is highly customizable and relies on a *template mechanism* that allows you to control the position of various functional *template components* to suit your particular requirements.

You can select from several different styles of layouts (for example, by default, you can select either a *tiles* or *tree* style of layout). Furthermore, each of these layouts include a collection of skins that you can choose from, or you can customize your own.

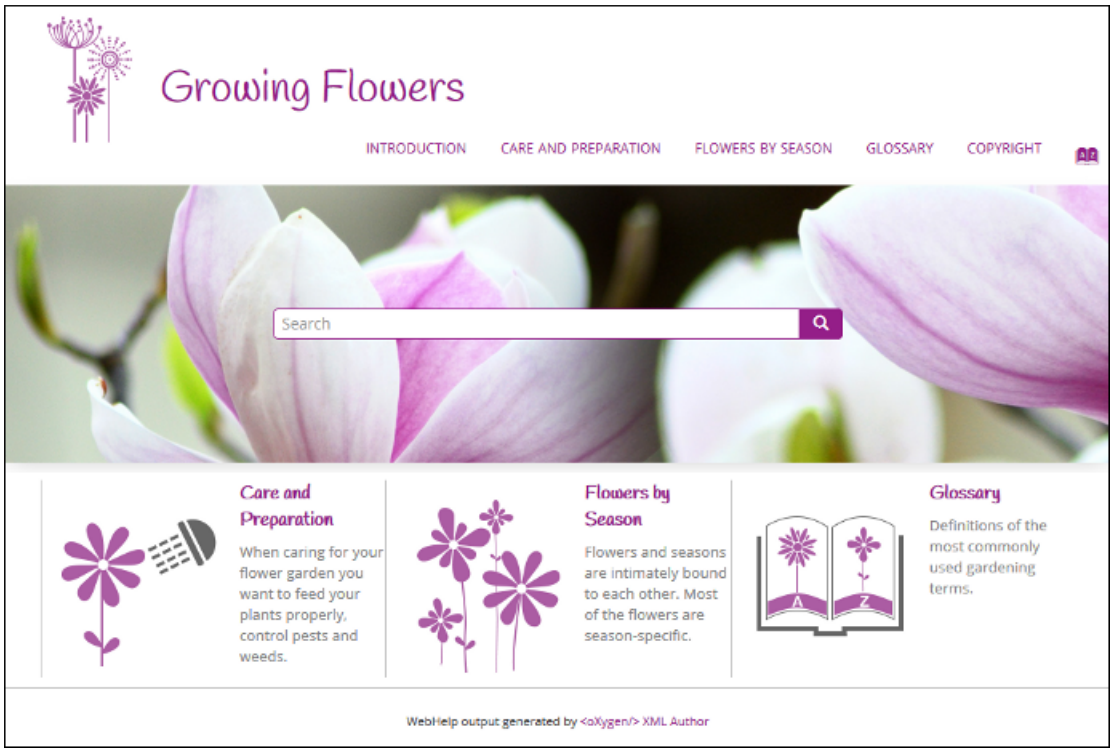

Figure 618: WebHelp Responsive Output on a Normal Screen

Figure 619: WebHelp Responsive Output on a Narrow Screen

WebHelp Responsive Search Engine
Search Rules

Rules that are applied during a search include:

- You can use quotes to perform an exact search for multiple word phrases (for example, *"grow flowers"* will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a *phrase search*.
- *Boolean Search* is supported using the following operators: *and*, *or*, *not*. When there are two adjacent search terms without an operator, *or* is used as the default search operator (for example, *grow flowers* is the same as *grow or flowers*).
- The space character separates keywords (an expression such as *grow flowers* counts as two separate keywords: *grow* and *flowers*).
- `indexterm` and `keywords` DITA elements are an effective way to increase the ranking of a page (for example, content inside a *keywords* element weighs more than an *H1* HTML element).
- Words composed by merging two or more words with colon (":"), minus ("-"), underline ("_"), or dot (".") characters count as a single word.
- Your search terms should contain two or more characters (note that stop words will be ignored). This rule does not apply to CJK (Chinese, Japanese, Korean) languages.

5-Star Rating Mechanism and Sorting

The **Search** feature is also enhanced with a rating mechanism that computes scores for every result that matches the search criteria. These scores are then translated into a 5-star rating scheme and the stars are displayed to the right of each result. The search results are sorted depending on the following:

- Search entries that satisfy the phrase search criterion are presented first.
- The number of keywords found in a single page (the higher the number, the better).
- The context (for example, a word found in a title scores better than a word found in unformatted text). The search ranking order, sorted by relevance is as follows:
  - The search term is included in a meta keyword
  - The search term is in the title of the page
  - The search term is in bold text in a paragraph
  - The search term is in normal text in a paragraph

Tag Element Scoring Values

HTML tag elements are also assigned a scoring value and these values are evaluated for the search results. For information about editing these values, see *Editing Scoring Values of Tag Elements in Search Results* on page 1186.

Excluded Terms

To improve performance, the **Search** feature excludes certain *stop words*. For example, the English version of such *stop words* include: *a, an, and, are, as, at, be, but, by, for, if, in, into, is, it, no, not, of, on, or, such, that, the, their, then, there, these, they, this, to, was, will, with*.

WebHelp Search Results Page

When you enter search terms in the **Search** field, the results are displayed in a results page. When you click on a result, the topic is opened in the main pane and the search results are highlighted. If you want to remove the colored highlights, click the **Toggle Highlights** button at the top-right side of the page. The **Search** field also includes an *autocomplete* feature.

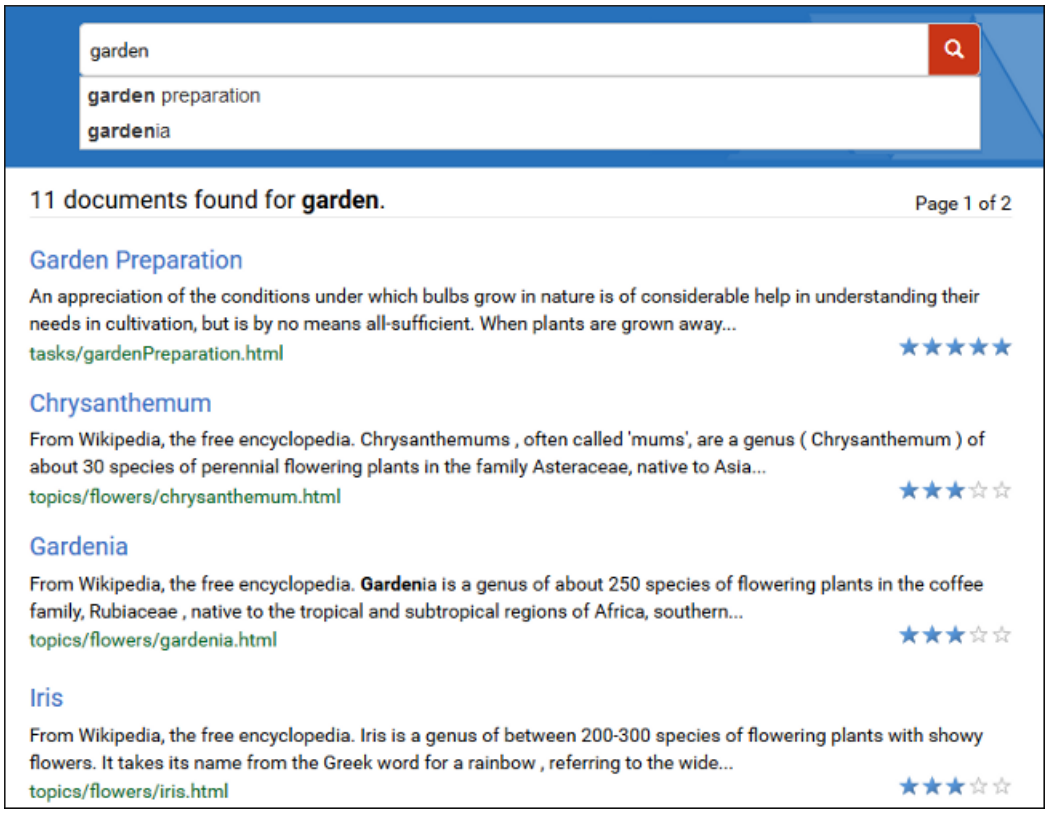

Figure 620: WebHelp Responsive Search Results Page

Autocomplete Suggestions in the Search Text Field

When you are typing in the search text field, proposals are presented to help you to compute the search query. The information proposed when you are typing is collected from:

- The search queries from the history of the previous searches.
- The titles collected from your documentation.
- Documentation index terms and keywords. For example, in a DITA topic, the keywords and index terms are specified in the topic prolog section like this:

```
<prolog>
  <metadata>
 <keywords><indexterm>databases</indexterm></keywords>
 <keyword>installing</keyword>
 <keyword>uninstalling</keyword>
    <keyword>prerequisites</keyword>
  </metadata>
</prolog>
```

Missing Terms

If you enter multiple search terms (other than *stop words*), for any result that the search engine found at least one term but not one or more of the other terms, the **Missing** terms will be listed below each result.

Browser Compatibility

This output format is compatible with the most recent versions of the following common browsers:

- Edge
- Internet Explorer (IE 10 or newer)
- Chrome
- Firefox
- Safari
- Opera

WebHelp Responsive with Feedback System

WebHelp is a form of online help that consists of a series of web pages (XHTML format). Its advantages include platform independence, ability to update content continuously, and it can be viewed using a regular web browser. The Oxygen XML Editor WebHelp system includes several variants to suit your specific needs. The **WebHelp Responsive with Feedback** variant features a very flexible layout, is designed to adapt to any screen size, and includes a feedback system that allows your users to make comments and allows you to manage and reply to them. This variant is available for DITA document types.

This type of WebHelp system can be generated by using the ***DITA Map WebHelp Responsive with Feedback*** *transformation scenario* and following the *instructions for deploying the system*.

Layout

The layout of the **WebHelp Responsive with Feedback** system is platform independent and is able to adapt to any screen size. It is highly customizable and relies on a *template mechanism* that allows you to control the position of various functional *template components* to suit your particular requirements.

You can select from several different styles of layouts (for example, by default, you can select either a *tiles* or *tree* style of layout). Furthermore, each of these layouts include a collection of skins that you can choose from, or you can customize your own.

The **WebHelp Responsive with Feedback** system also contains a **Comments** section at the bottom of the pane. This section is where you can interact with users through a comment system.

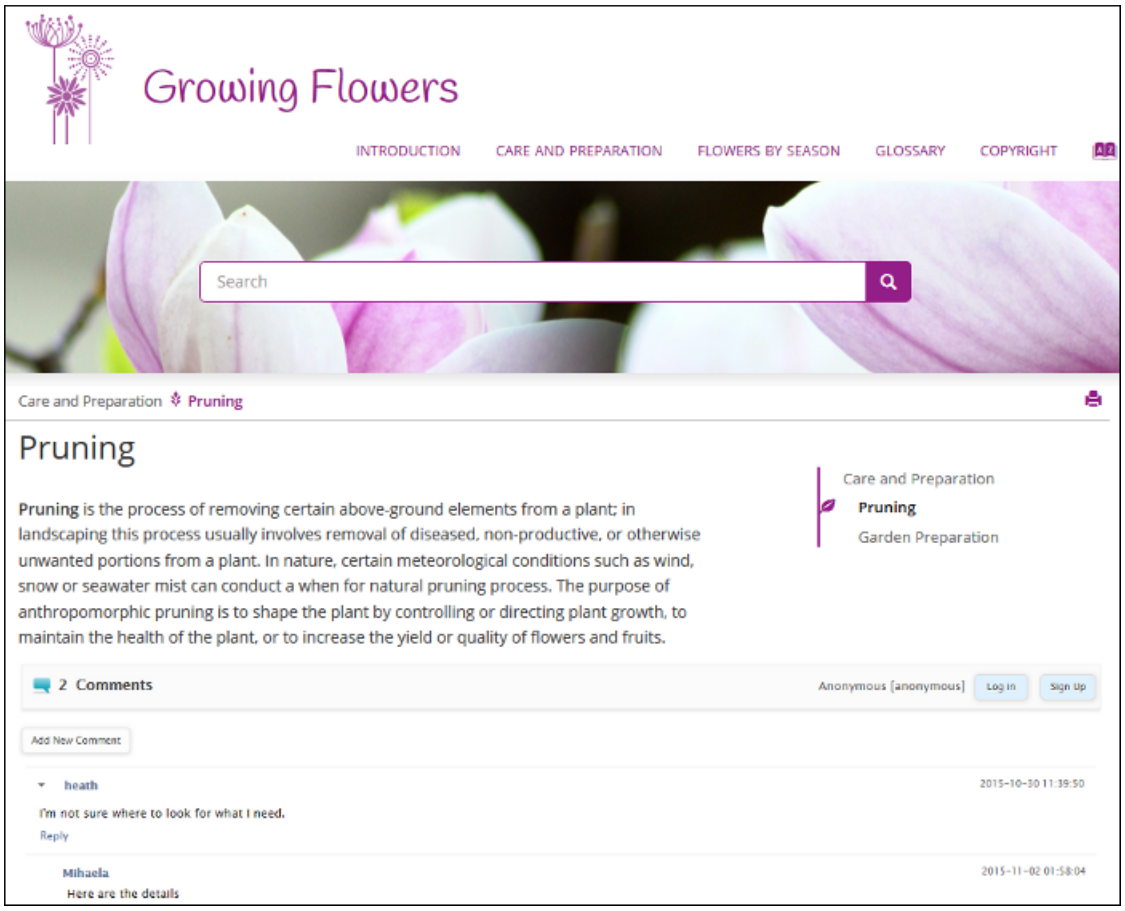

Figure 621: WebHelp Output

Managing Comments

To add a new comment, click the **Add New Comment** button, or click **Reply** to add a comment to an existing thread. You can click on the **Log in** button on the right side of this bar to be authenticated as a user and your user

name will be included in any comments that you add. If you do not have a user name, you can click on the **Sign Up** button to create a new user.

After you log in, your name and user name are displayed in the **Comments** bar, along with the **Log off** and **Edit** buttons. Click the **Edit** button to open the **User Profile** dialog box where you can customize the following options:

- **Your Name** - You can use this field to edit the initial name that you used to create your user profile.
- **Your email address** - You can use this field to edit the initial email address that you used to create your profile.
- You can choose to receive an email in the following situations:
  - When a comment is left on a page that you commented on.
  - When a comment is left on any topic in the WebHelp Classic system.
  - When a reply is left to one of my comments.
- **New Password** - Allows you to enter a new password for your user account.

  Note: The **Current Password** field from the top of the **User Profile** is mandatory if you want to save the changes you make.

If you are an administrator, you can manage user information and comments. For more information, see *Managing Users and Comments in a Feedback-Enabled WebHelp System* on page 1162.

WebHelp Responsive Search Engine
Search Rules

Rules that are applied during a search include:

- You can use quotes to perform an exact search for multiple word phrases (for example, *"grow flowers"* will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a *phrase search*.
- *Boolean Search* is supported using the following operators: *and*, *or*, *not*. When there are two adjacent search terms without an operator, *or* is used as the default search operator (for example, *grow flowers* is the same as *grow or flowers*).
- The space character separates keywords (an expression such as *grow flowers* counts as two separate keywords: *grow* and *flowers*).

Context-Sensitive WebHelp Responsive System on page 1201

Deploying a Feedback-Enabled WebHelp System

System Requirements

The feedback-enabled WebHelp system of Oxygen XML Editor requires a standard server deployment. You can request this from your server admin and it needs the following system components:

- A Web server (such as *Apache Web Server*)
- A *MySQL* or *MariaDB* database server
- A database admin tool (such as *phpMyAdmin*)
- PHP Version 5.1.6 or later

Oxygen XML WebHelp system supports most of the recent versions of the following browsers: Chrome, Firefox, Edge, Internet Explorer, Safari, Opera.

Create WebHelp with Feedback Database

The **WebHelp with Feedback** system needs a database to store user details and the actual feedback, and a user added to it with all privileges. After this is created, you should have the following information:

- Database name
- Username
- Password

Exactly how you create the database and user depends on your web host and your particular needs.

Example:

The following procedure uses *phpMyAdmin* to create a MySQL database for the feedback system and a MySQL user with privileges for that database. The feedback system uses these credentials to connect to the database.

Using *phpMyAdmin* to create a database:

1. Access the *phpMyAdmin* instance running on your server.
2. Click *Databases* (in the right frame) and then create a *database*. You can give it any name you want (for example *comments*).
3. Create a user with connection privileges for this database.
4. Under *localhost*, in the right frame, click *Privileges* and then at the bottom of the page click the **reload the privileges** link.

Deploying the WebHelp with Feedback Output

If you have a web server configured with PHP and MySQL, you can deploy the **WebHelp with Feedback** output by following these steps:

1. Connect to your server using an FTP client.
2. Locate the home directory (from now on, referred to as *DOCUMENT_ROOT*) of your server.
3. Copy the transformation output folder into the `DOCUMENT_ROOT` folder.

4. Rename it to something relevant (for example, `myProductWebHelp`).
5. Open the output folder (for example, `http://[YOUR_SERVER]/myProductWebHelp/`). You are redirected to the installation wizard. Proceed with the installation as follows:
   a. Verify that the prerequisites are met.
   b. Press **Start Installation**.
   c. Configure the **Deployment Settings** section. Default values are provided, but you should adjust them as needed.

      Tip: You can change some of the options later. The installation creates a `config.php` file in `[OXYGEN_WEBHELP_INSTALL_DIR]/feedback/resources/php/config/config.php` where all your configuration options are stored.
   d. Configure the **MySql Database Connection Settings** section. Use the information (database name, username, password) from the *Create WebHelp with Feedback Database section* to fill-in the appropriate text boxes.

      Warning: Selecting the **Create new database structure** option will overwrite any existing data in the selected database, if it already exists. Therefore, it is useful the first time you install the **WebHelp with Feedback** system, but you do not want to select this option on subsequent deployments.
   e. If you are using a domain (such as *OpenLDAP* or *Active Directory*) to manage users in your organization, select the **Enable LDAP Autehntication** option. This will allow you to configure the LDAP server, which will provide information and credentials for users who will access the WebHelp system. Also, this will allow you to choose which of the domain users will have administrator privileges.
   f. If the **Create new database structure** option is selected, the **Create WebHelp Administrator Account** section becomes available. Here you can set the administrator account data. The administrator is able to moderate new posts and manage WebHelp users.

      The same database can be used to store comments for multiple **WebHelp with Feedback** deployments. If a topic is available in multiple deployments and there are comments associated with it, you can choose to display the comments in all deployments that share the database. To do this, select the **Display comments from other products** option. In the **Display comments from** section, a list with the deployments sharing the same database is displayed. Select the deployments allowed to share common feedback.

      Note: You can restrict the displayed comments of a product depending on its version. If you have two products that use the same database and you restrict one of them to display comments starting from a certain version, the comments of the other product are also displayed from the specified version onwards.
   g. Press **Next Step**.
   h. Remove the installation folder from your web server.

      Important: When you publish subsequent iterations of your **WebHelp with Feedback** system, you will not upload the `/install` folder in the output, as you only need it uploaded the first time you create the installation. On subsequent uploads, you will just upload the other output files.
   i. In your Web browser, go to your **WebHelp with Feedback** system main page.

Testing Your WebHelp with Feedback System

To test your system, create a user and post a comment. Check to see if the notification emails are delivered to your email inbox.

Note: To read debug messages generated by the system:

1. Enable *JavaScript* logging by doing one of the following:
   - Open the `log.js` file, locate the `var log= new Log(Level.NONE);` line, and change the logging level to: `Level.INFO`, `Level.DEBUG`, `Level.WARN`, or `Level.ERROR`.
   - Append `?log=true` to the WebHelp URL.
2. Inspect the PHP and Apache server log files.

Documentation Product ID and Version

When you run a **WebHelp with Feedback** transformation scenario, by default you are prompted for a documentation product ID and version number. This is needed when multiple WebHelp systems are deployed on

the same server. Think of your WebHelp output as a *product*. If you have three different WebHelp outputs, you have three different *products* (each with their own unique documentation product ID). This identifier is included in a configuration file so that comments are tied to a particular output (product ID and version number).

Note: The **WebHelp with Feedback** installation includes a configuration option (**Display comments from other products**) that allows you to choose to have comments visible in other specified *products*.

Related Information:

Managing Users and Comments in a Feedback-Enabled WebHelp System on page 1162

Refreshing the Content of a Feedback-Enabled WebHelp System

It is common to update the content of an existing installation of a **WebHelp with Feedback** system on a regular basis. In this case, reinstalling the whole system is not a viable option since it might result in the loss of the comments associated with your topics. Also, reconfiguring the system every time you want to refresh it may be time consuming.

Fortunately, you can refresh just the content without losing the comments or the initial system configuration. To do so, follow these steps:

1. Execute the transformation scenario that produces the *WebHelp with Feedback* output directory.
2. Go to the output directory (specified in the **Output** tab of the transformation scenario), locate the `\feedback\resources\php\config\config.php` file, and delete it.
3. Locate the `\feedback\install` directory and delete it.
4. Copy the remaining structure of the output folder and paste it into your *WebHelp with Feedback* system installation directory, overwriting the existing content.

Managing Users and Comments in a Feedback-Enabled WebHelp System

When you installed the **WebHelp with Feedback** system the first time (assuming the ***Create new database structure** option* was selected), you should have been prompted to create an administrator account (or a user named *administrator* was created by default). As an administrator, you have access to manage comments posted in your feedback-enabled WebHelp system. You can also manage the user information (such as role, status, or notification options).

To manage comments and user information, follow these steps:

1. At the bottom of each specific topic there is a **Comments** navigation bar and on the right side there is a **Log in** button. Click this button and log in with your administrator credentials. This gives you access to an **Admin Panel** button.
2. Click the **Admin Panel** button to display an administration page.

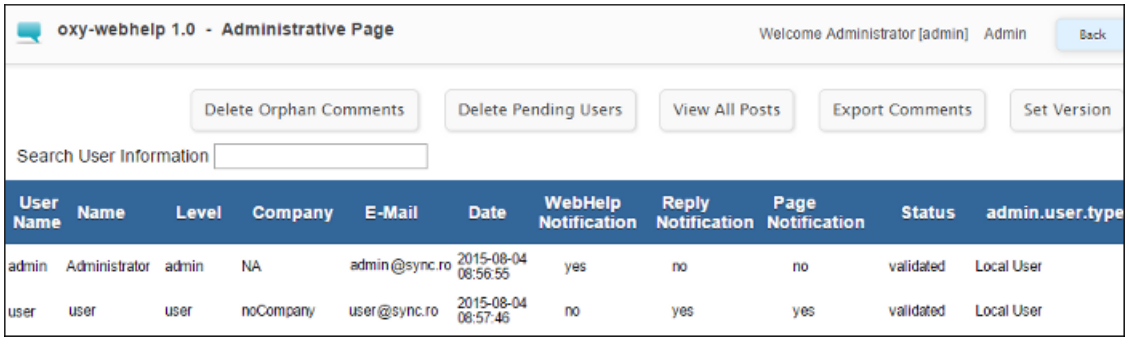

Figure 623: Administrative Page

3. Use this page to manage the following options:

   Delete Orphaned Comments

   Allows you to delete comments that are no longer associated with a topic in your WebHelp system.

   Delete Pending Users

   Allows you to delete user accounts that you do not wish to activate.

   View All Posts

   Allows you to view all the comments that are associated with topics in your WebHelp system.

Export Comments

Allows you to export all posts associated with topics in your WebHelp system into an XML file.

Set Version

Use this action to display comments starting with a particular version.

Manage User Information

To edit the details for a user, click on the corresponding row. This opens a window that allows you to customize the following information associated with the user:

Name

The full name of the user.

Level

Use this field to modify the privilege level (role) for the selected user. You can choose from the following:

- **User** - Regular user, able to post comments and receive e-mail notifications.
- **Moderator** - In addition to the regular **User** rights, this type of user has access to the **Admin Panel** where a moderator can view, delete, export comments, and set the version of the feedback-enabled WebHelp system.
- **Admin** - Full administrative privileges. Can manage WebHelp-specific settings, users, and their comments.

Company

The name of the organization associated with the user.

E-Mail

The contact email address for the user. This is also the address where the WebHelp system sends notifications.

WebHelp Notification

When selected, the user receives notifications when comments are posted anywhere in your feedback-enabled WebHelp system.

Reply Notification

When selected, the user receives notifications when comments are posted as a reply to one of their comments.

Page Notification

When selected, the user receives notifications when comments are posted on a topic where they previously posted a comment.

Date

The date the user registered is displayed.

Status

Use this drop-down list to change the status of the user. You can choose from the following:

- **Created** - The user is created but does not yet have any rights for the feedback-enabled WebHelp system.
- **Validated** - The user is able to use the feedback-enabled WebHelp system.
- **Suspended** - The user has no rights for the feedback-enabled WebHelp system.

Warning: The key used for identifying the page a comment is attached to is the relative file path to the output page. Since the output file and folder names mirror the source, any change to the file name (or its folder) in the source will affect the comments associated with that WebHelp page. If you change the file name or path, the comment history for that topic will become orphaned (a change to the topic ID does not affect the comment history).

WebHelp Responsive Template Mechanism

The WebHelp Responsive template mechanism is the base of the system and it is responsible for defining its output. It consists of a set of HTML template files and other additional resources (such as images, CSS, and

JavaScript files). Each of the HTML template files contain one or more template components (such as title, table of contents, search input, etc.) whose placement inside the template will define the final layout of the output.

This mechanism allows you to create multiple layouts simply by creating templates that define the location of where the various components will be displayed.

Creating WebHelp Responsive Templates

To create a new WebHelp Responsive template, follow these steps:

1. Locate the following folder in your DITA-OT directory (*DITA-OT-DIR*):

   ```
   DITA-OT-DIR/plugins/com.oxygenxml.webhelp/templates/dita/
   ```

2. Duplicate the `bootstrap` folder and rename it to whatever you want your new template to be identified as (for example, `myTemplate`).
3. Customize the structure of the new template according to your needs. For example, if you only want to keep one of the template variants, open the `myTemplate/variants` folder and delete all of its subdirectories, except for that one (for instance, the `tiles` directory). Keep in mind that the structure of the template directory is important. The names of folders at certain levels correspond to the names of templates and skins, while components and resources are defined and referenced in certain files or folders at specific locations within the directory structure. For more information, see *WebHelp Responsive Template Directory Structure* on page 1164.
4. You can also customize the structure of the skins within the template variants. For example, if you only want to keep one of the skins in the `tiles` variant, open the `myTemplate/variants/tiles` folder and delete all of its subdirectory skins, except for that one (for instance, the `light` directory). You can also edit the `skin.css` file that is located in the skin directory to customize the styling. If your customization of the CSS file requires additional resources (such as images, fonts, or other CSS files), they need to be placed in the `resources` folder at the same level with the `skin.css` file.
5. To customize the components that appear in the WebHelp Responsive output, you can modify the HTML template files that define the output. For more information, see *WebHelp Responsive Template Files* on page 1166.

Related Information:

Customizing the WebHelp Responsive Output on page 1175

WebHelp Responsive Template Directory Structure

A certain directory structure is required for the WebHelp Responsive templates. The names of folders at certain levels correspond to the names of template variants and skins, components are defined in specific files, and various resources need to be located in specific locations within the directory structure.

The templates are stored in *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita`.

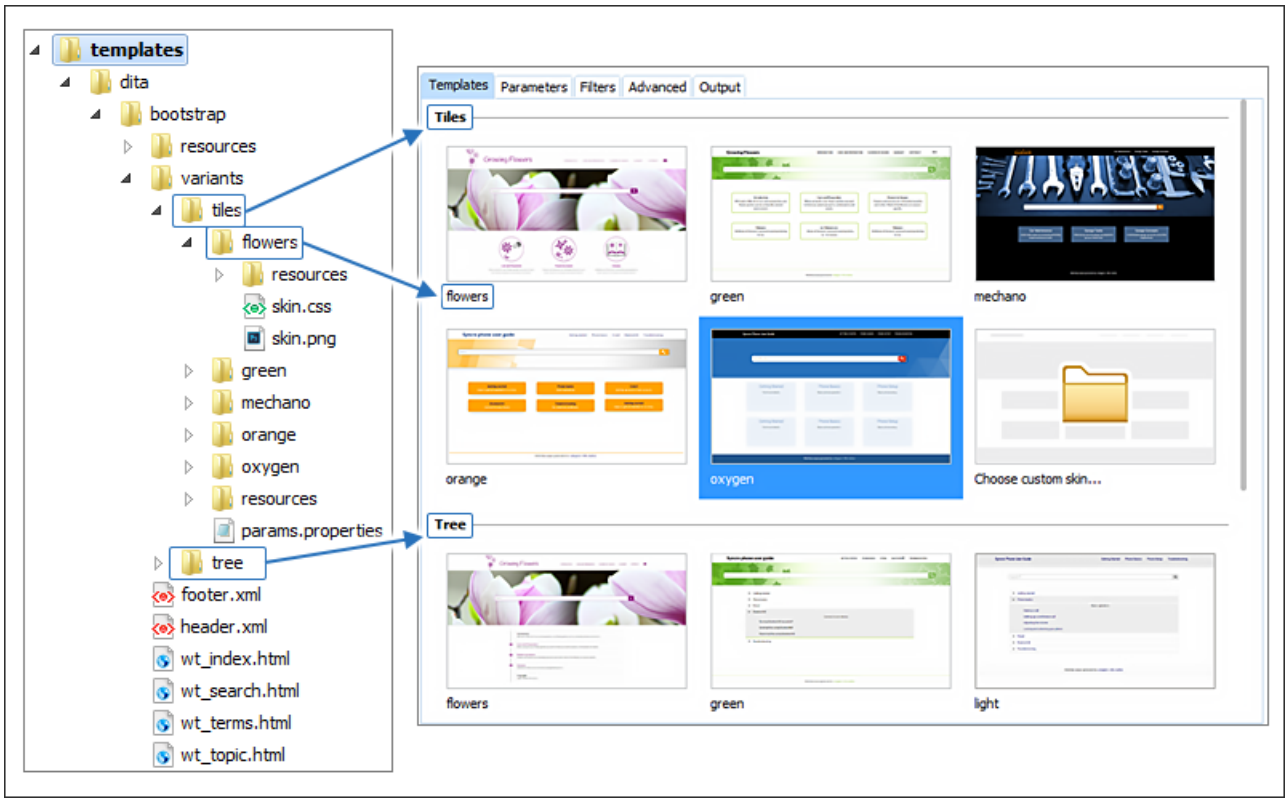

Figure 624: Templates Directory Structure

At the first level of the template directory we can find the following predefined files and folders:

- **`resources` Folder** - Contains all additional resources used by the template, such as images, CSS, and JavaScript files.
- **`variants` Folder** - Contains the template variants, including folders for each skin. See *Template Variants and Skins* on page 1165.
- **Template Files** - The HTML template files that are used to generate the output:
  - `wt_index.html` - Used to produce the main home page of the WebHelp Responsive output. See *WebHelp Responsive Main Page Template* on page 1166.
  - `wt_topic.html` - Used to generate the HTML pages associated with individual topics. See *WebHelp Responsive Topic Template* on page 1168.
  - `wt_search.html` - Used to generate the HTML page that presents the search results. See *WebHelp Responsive Search Results Template* on page 1169.
  - `wt_terms.html` - Used to generate the HTML page that presents the documentation index. See *WebHelp Responsive Index Terms Template* on page 1169.

After the transformation scenario is executed, the resources and variants folders are copied in the `/oxygen-webhelp/template/` folder within the output directory (defined in the **Output** tab of the transformation scenario).

Template Variants and Skins

You could think of a *template* as being a set of WebHelp components that are placed in a predefined HTML layout. You can have multiple variants of the template. A WebHelp *template variant* is an instance of the template with a specific set of parameters. For example, you could have two variants of the WebHelp main page, one that displays the topics in a *tiles* style of layout, and another one that displays the topics in a *tree* style.

Each variant has its own directory that corresponds to the name of the variant. The name of the variant is displayed in the user interface when the variants are displayed (for example, in the **templates** tab of the transformation scenario).

Each variant directory may contain the following resources:

- **Skin Directories** - These folders represent skin templates for the current variant.
- **`params.properties` File** - This file specifies the values for the parameters imposed by the variant.
- **`resources` Folder** - This is an optional directory that contains resources that are specific to the current variant (such as images, CSS files, etc.) They will be copied to the output directory.

Skins

A variant *skin* represents a CSS file that allows you to alter the styling of the template. The CSS associated with a skin must be named **`skin.css`** and it must be stored as a first child of the skin directory.

Each skin might need additional resources (images, fonts) that must be stored in the `resources` directory in the root folder for that particular skin. The name of the skin directory is displayed in the user interface when you choose a skin (in the **templates** tab of the transformation scenario).

Each skin directory can also contain a **`skin.png`** preview image that will be displayed in the user interface and a properties file that contains a URL for the online preview of the skin. This image file must be stored as a first child of the skin directory.

For information about creating or customizing skins, see *Create or Customize a WebHelp Responsive Skin* on page 1178.

WebHelp Responsive Template Files

The HTML pages that comprise the output of a WebHelp Responsive system are obtained after processing HTML template files. These files correspond to the type of page they generate in the output.

There are four types of template pages and corresponding HTML template files:

1. **Main Page Template** (`wt_index.html` file) - Used to produce the main home page of the WebHelp Responsive output.
2. **Topic Template** (`wt_topic.html` file) - Used to generate the HTML pages associated with individual topics.
3. **Search Results Template** (`wt_search.html` file) - Used to generate the HTML page that presents the search results.
4. **Index Terms Template** (`wt_terms.html` file) - Used to generate the HTML page that presents the documentation index.

The HTML template files are located in the following directory:

```
DITA-OT-DIR/plugins/com.oxygenxml.webhelp/templates/dita/bootstrap/
```

WebHelp Responsive Main Page Template

The *Main Page Template* is used to generate the home page of the WebHelp Responsive output. The name of the template file is `wt_index.html` and it is located in the following directory:

```
DITA-OT-DIR/plugins/com.oxygenxml.webhelp.responsive/templates/dita/bootstrap/
```

The main function of the home page is to display top level information and provide links that help you easily navigate to any of the top level topics of the publication. These links can be rendered in either a *Tiles* or *Tree* style of layout. The HTML page produced for the home page also consists of various other components, such as a logo, title, menu, search field, or index link.

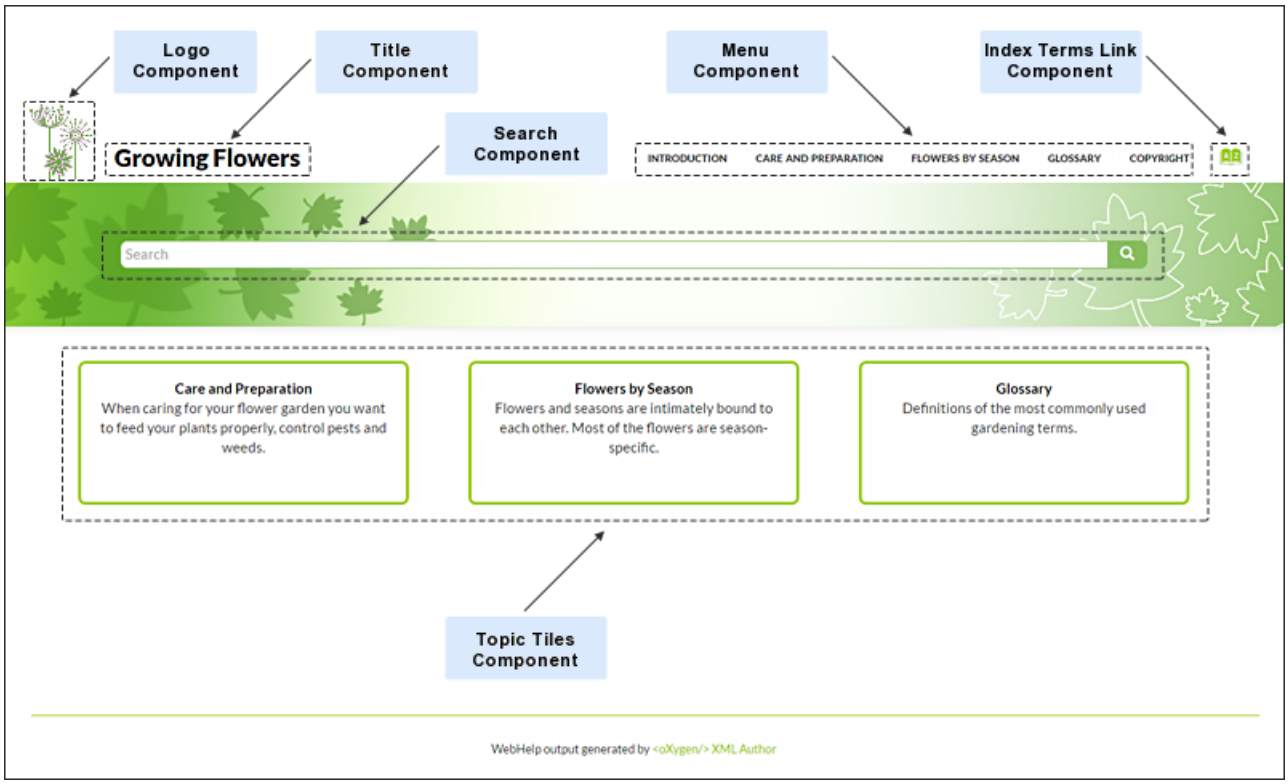

Figure 625: Examples of Main Page Components for a Tiles Style of Layout

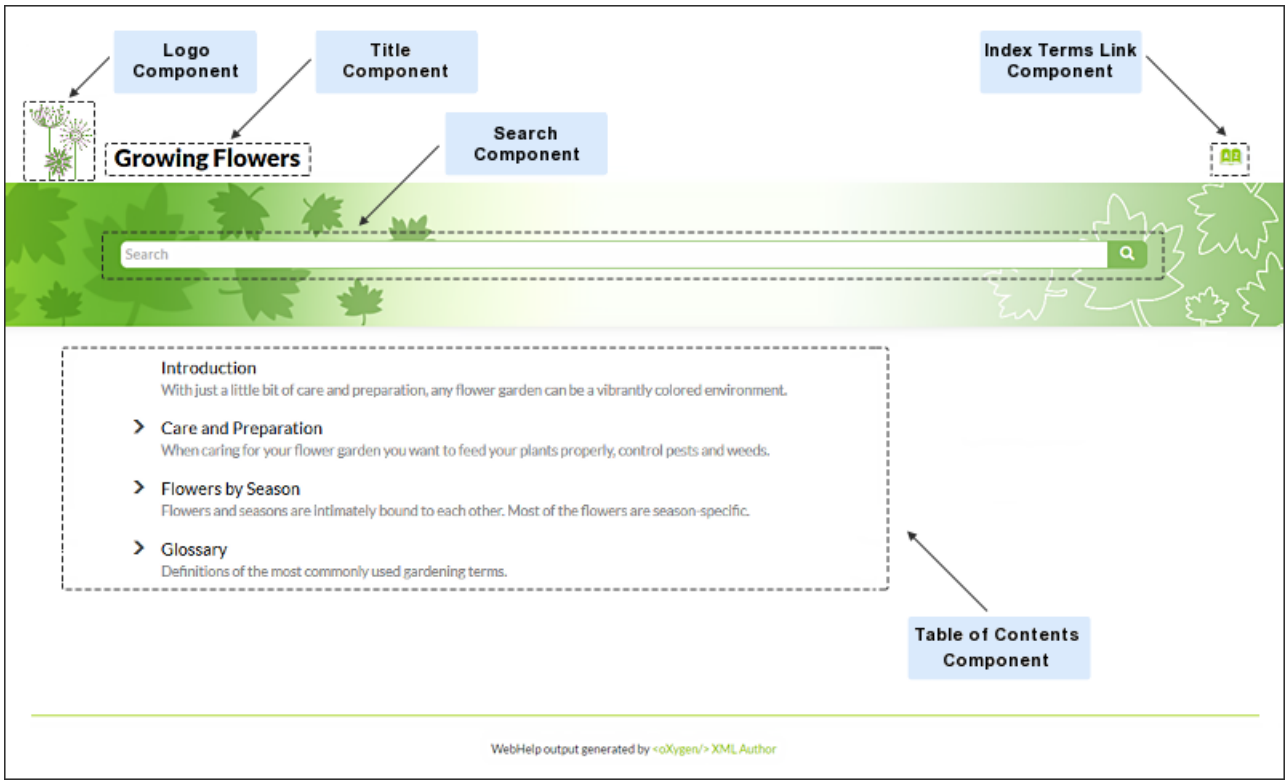

Figure 626: Examples of Main Page Components for a Tree Style of Layout

The components that can be referenced in the `wt_index.html` template file are as follows:

- *Publication Title*
- *Publication Logo*
- *Search Input*

- *Print Link*
- *Main Page Menu*
- *Main Page Topic Tiles*
- *Main Page Table of Contents*
- *Index Terms Link*
- *Link to Skin Resources*

WebHelp Responsive Topic Template

The *Topic Template* is used to generate HTML pages for each topic in the WebHelp Responsive output. The name of the template file is `wt_topic.html` and it is located in the following directory:

```
DITA-OT-DIR/plugins/com.oxygenxml.webhelp/templates/dita/bootstrap/
```

The HTML pages produced for each topic consist of the topic content along with various other additional components, such as a title, menu, navigation breadcrumb, print icon, or side table of contents.

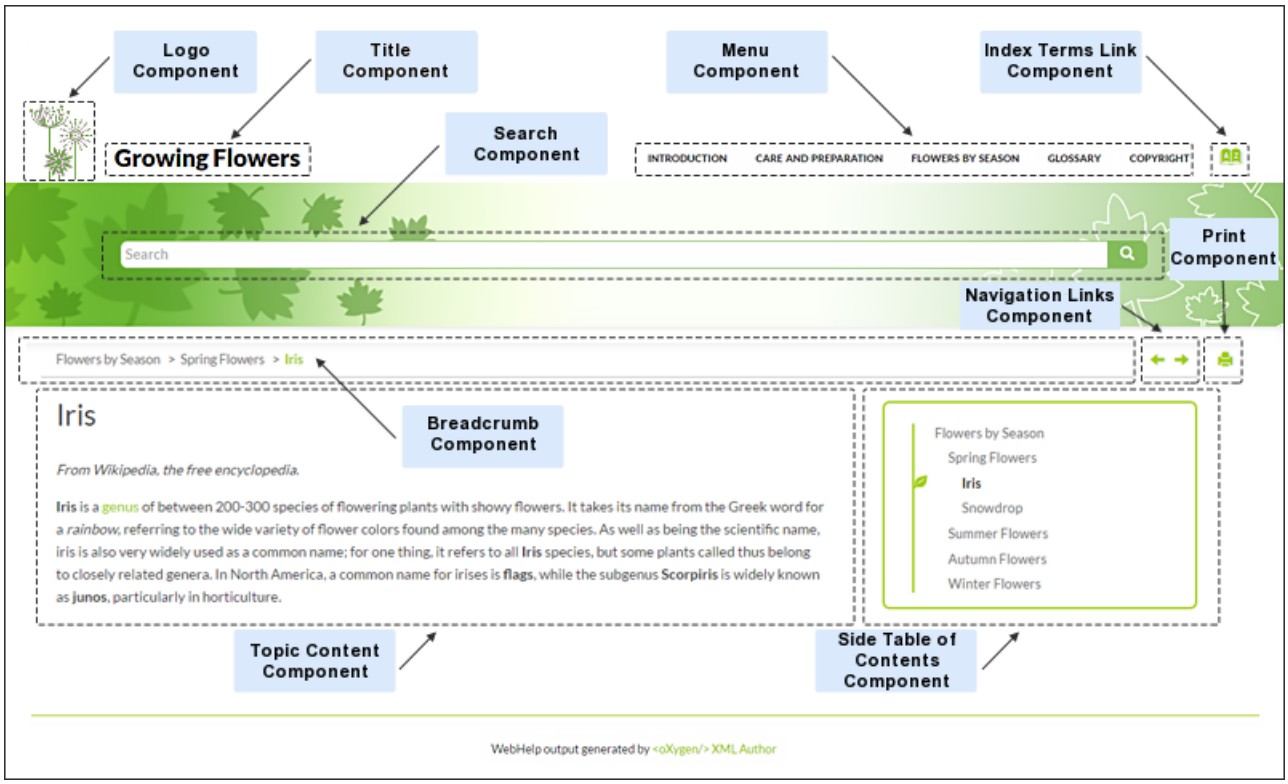

Figure 627: Examples of Topic Page Components

The components that can be referenced in the `wt_topic.html` template file are as follows:

- *Publication Title*
- *Publication Logo*
- *Search Input*
- *Topic Breadcrumb*
- *Navigational Links*
- *Print Link*
- *Topic Content*
- *Topic Side TOC*
- *Topic Feedback*
- *Main Page Menu*
- *Index Terms Link*
- *Child Links*
- *Related Links*

- *Link to Skin Resources*

WebHelp Responsive Search Results Template

The *Search Results Template* is used to generate HTML pages that present search results in the WebHelp Responsive output. The name of the template file is `wt_search.html` and it is located in the following directory:

```
DITA-OT-DIR/plugins/com.oxygenxml.webhelp/templates/dita/bootstrap/
```

The HTML page that is produced consists of a search results component along with various other additional components, such as a title, menu, or index link.

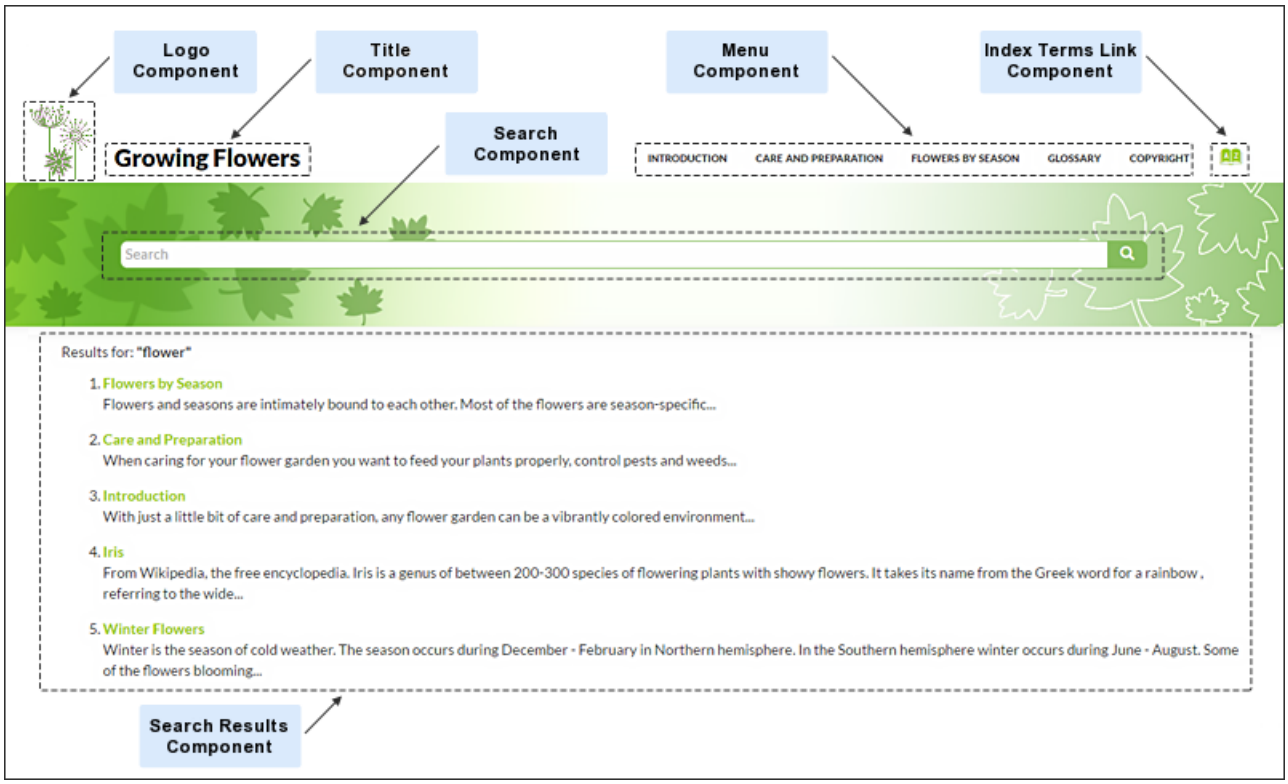

Figure 628: Examples of Search Results Page Components

The components that can be referenced in the `wt_search.html` template file are as follows:

- *Publication Title*
- *Publication Logo*
- *Search Input*
- *Search Results*
- *Print Link*
- *Main Page Menu*
- *Index Terms Link*
- *Link to Skin Resources*

WebHelp Responsive Index Terms Template

The *Index Terms Template* is used to generate HTML pages that present index terms in the WebHelp Responsive output. The name of the template file is `wt_terms.html` and it is located in the following directory:

```
DITA-OT-DIR/plugins/com.oxygenxml.webhelp/templates/dita/bootstrap/
```

The HTML page that is produced consists of an index terms section along with various other additional components, such as a title, menu, or search field.

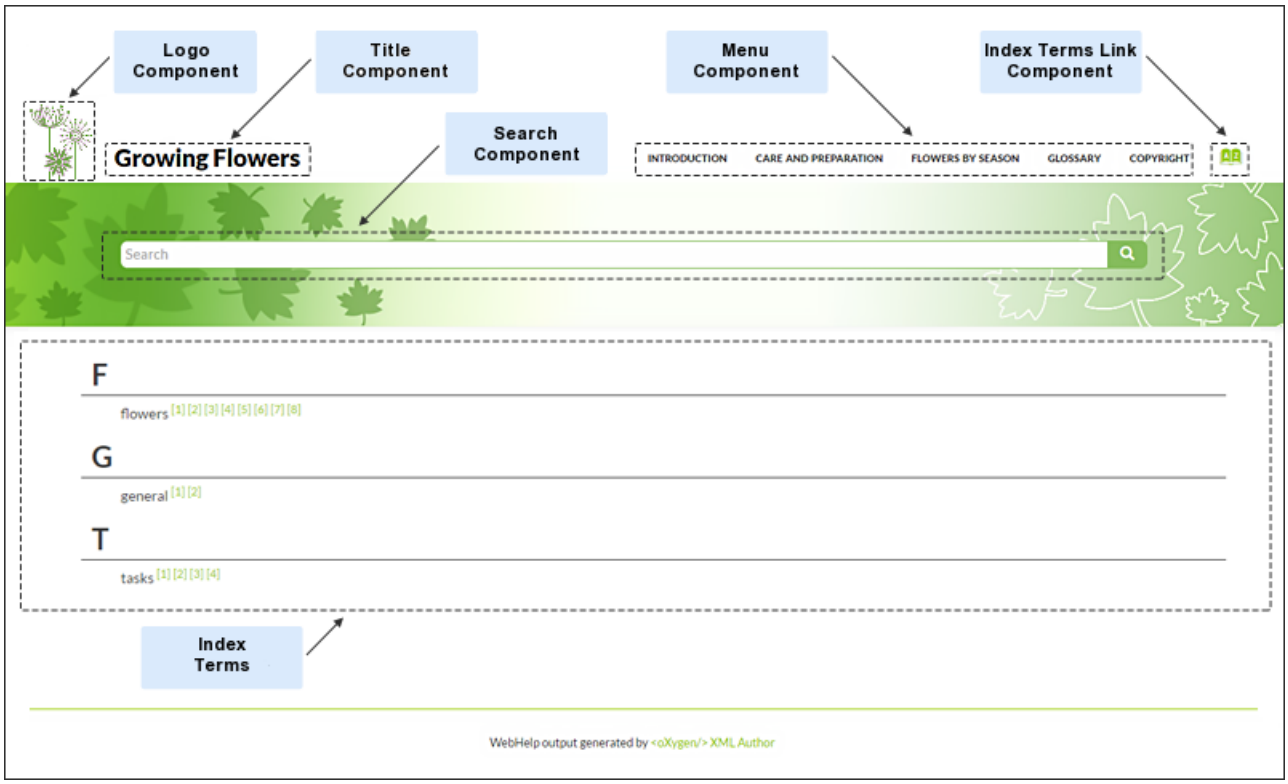

Figure 629: Examples of Index Terms Page Components

The components that can be referenced in the `wt_terms.html` template file are as follows:

- *Publication Title*
- *Publication Logo*
- *Search Input*
- *Print Link*
- *Main Page Menu*
- *Index Terms Link*
- *Link to Skin Resources*

WebHelp Responsive Template Components

A WebHelp Responsive *template component* adds dynamics to a WebHelp *template page*. The rendering of a component depends on the context of where it is placed and its content depends on the transformed *DITA map*.

Some of the template components can be used in all the *types of template pages*, while some are only available for certain template pages. For instance, the *Publication Title* component can be used in all pages, but the *Navigation Breadcrumb* component can only be used in *Topic Template* pages.

To include a *template component* in the output of a particular type of *template page*, you have to reference a specific element in the particular *template file*. All the elements associated with a template component should belong to the `http://www.oxygenxml.com/webhelp/components` namespace.

Every component could contain custom content or reference another component. To specify where the component content will be located in the output you can use the `component_content` element as a descendant of the component element.

Example:

```
<whc:webhelp_search_input class="navbar-form wh_main_page_search"
                role="form" >
        <whc:include_html href="{$webhelp.include.before.search}"/>
  <div class="search_input">
   <whc:component_content/>
  </div>
</whc:webhelp_search_input>
```

The various components and where they can be used are as follows:

Publication Title [webhelp_publication_title]

This component generates the publication title in the output. To generate this component, the `webhelp_publication_title` element must be specified in the template file. It can be used in all four types of template pages:

- ***Main Page Template*** *(wt_index.html file)*
- ***Topic Template*** *(wt_topic.html file)*
- ***Search Results Template*** *(wt_search.html file)*
- ***Index Terms Template*** *(wt_terms.html file)*

In the template file, the `webhelp_publication_title` element can be specified as in the following example:

```
<whc:webhelp_publication_title
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_publication_title`.

Publication Logo [webhelp_logo]

This component generates a logo image in the output. To generate this component, the `webhelp_logo` element must be specified in the template file. It can be used in all four types of template pages:

- ***Main Page Template*** *(wt_index.html file)*
- ***Topic Template*** *(wt_topic.html file)*
- ***Search Results Template*** *(wt_search.html file)*
- ***Index Terms Template*** *(wt_terms.html file)*

In the template file, the `webhelp_logo` element can be specified as in the following example:

```
<whc:webhelp_logo
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In addition, you must also specify the path of the logo image in the `webhelp.logo.image` transformation parameter (in the **Parameters** tab in the transformation scenario). You can set the `webhelp.logo.image.target.url` parameter to generate a link to a URL when you click the logo image. If this parameter is not set, a link to the home page will automatically be generated.

In the output, you will find an element with the class: `wh_logo`.

Search Input [webhelp_search_input]

This component is used to generate the input widget associated with search function in the output. To generate this component, the `webhelp_search_input` element must be specified in the template file. It can be used in all four types of template pages:

- ***Main Page Template*** *(wt_index.html file)*
- ***Topic Template*** *(wt_topic.html file)*
- ***Search Results Template*** *(wt_search.html file)*
- ***Index Terms Template*** *(wt_terms.html file)*

In the template file, the `wh_search_input` element can be specified as in the following example:

```
<whc:webhelp_search_input
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_search_input`.

Search Results [webhelp_search_results]

This component is used to generate a placeholder to signal where the search results will be presented in the output. To generate this component, the `webhelp_search_results` element must be specified in the template file. It can be used in the following type of template page:

- ***Search Results Template*** *(wt_search.html file)*

In the template file, the `webhelp_search_results` element can be specified as in the following example:

```
<whc:webhelp_search_results
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_search_results`.

Topic Breadcrumb [webhelp_breadcrumb]

This component generates a breadcrumb that displays the path of the current topic. To generate this component, the `webhelp_breadcrumb` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_breadcrub` element can be specified as in the following example:

```
<whc:webhelp_breadcrumb
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_breadcrumb`. This element will contain a list with items that correspond to the topics in the path. The first item in the list has a link to the main page with the `home` class. The last item in the list corresponds to the current topic and has the `active` class set.

Navigational Links [webhelp_navigation_links]

This component generates navigation links to the next and previous topics. To generate this component, the `webhelp_navigation_links` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_navigation_links` element can be specified as in the following example:

```
<whc:webhelp_navigation_links
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_navigation_links`. This element will contain the links to the next and previous topics.

Topic Content [webhelp_topic_content]

This component generates the content of a topic and it represent the content of the HTML files as they are produced by the DITA-OT processor. To generate this component, the `webhelp_topic_content` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_topic_content` element can be specified as in the following example:

```
<whc:webhelp_topic_content
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_topic_content`.

Topic Side TOC [webhelp_side_toc]

This component generates a mini table of contents for the current topic. It will contain links to the children of current topic, its siblings, and all of its ancestors. To generate this component, the `webhelp_side_toc` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_side_toc` element can be specified as in the following example:

```
<whc:webhelp_side_toc
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_side_toc`. This element will contain links to the topics that are close to the current topic.

Topic Feedback [webhelp_feedback]

This component generates a placeholder for where the comments section will be presented. To generate this component, the `webhelp_feedback` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_feedback` element can be specified as in the following example:

```
<whc:webhelp_feedback
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

Child Links [webhelp_child_links]

For all topics with subtopics (child topics), this component generates a list of links to each child topic. To generate this component, the `webhelp_child_links` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_child_links` element can be specified as in the following example:

```
<whc:webhelp_child_links
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

Related Links [webhelp_related_links]

For all topics that contain related links, this component generates a list of related links that will appear in the output. To generate this component, the `webhelp_related_links` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_related_links` element can be specified as in the following example:

```
<whc:webhelp_related_links
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

Main Page Topic Tiles [webhelp_tiles]

This component generates the tiles section in the main page. This section will contain a tile for each root topic of the published documentation. Each topic tile has three sections that corresponds to the topic title, short description, and image. To generate this component, the `webhelp_tiles` element must be specified in the template file. It can be used in the following type of template page:

- ***Main Page Template*** *(wt_index.html file)*

In the template file, the `webhelp_tiles` element can be specified as in the following example:

```
<whc:webhelp_tiles
```

```
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_tiles`.

If you want to control the HTML structure that is generated for a WebHelp tile you can also specify the template for a tile by using the `whc:webhelp_tile` component, as in the following example:

```
<whc:webhelp_tile class="col-md-4">
  <!-- Place holder for tile's image -->
  <whc:webhelp_tile_image/>

  <div class="wh_tile_text">
    <!-- Place holder for tile's title -->
     <whc:webhelp_tile_title/>

     <!-- Place holder for tile's shordesc -->
     <whc:webhelp_tile_shortdesc/>
  </div>
</whc:webhelp_tile>
```

For information about customizing the tiles, see *Configuring the Tiles on the Main Page* on page 1183.

Main Page Table of Contents [webhelp_main_page_toc]

This component generates a simplified Table of Contents. It is simplified because it contains only two levels from the documentation hierarchy. To generate this component, the `webhelp_main_page_toc` element must be specified in the template file. It can be used in the following type of template page:

- ***Main Page Template*** *(wt_index.html file)*

In the template file, the `webhelp_main_page_toc` element can be specified as in the following example:

```
<whc:webhelp_main_page_toc
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_main_page_toc`.

Main Page Menu [webhelp_topics_menu]

This component generates a menu with all the documentation topics. To generate this component, the `webhelp_topics_menu` element must be specified in the template file. It can be used in the following type of template page:

- ***Main Page Template*** *(wt_index.html file)*

In the template file, the `webhelp_topics_menu` element can be specified as in the following example:

```
<whc:webhelp_topics_menu
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_topics_menu`.

You can control the maximum level of topics that will be included in the menu using the `webhelp.top.menu.depth` transformation parameter (in the **Parameters** tab of the transformation scenario.

For information about customizing the menu, see *Customizing the Menu* on page 1185.

Print Link [webhelp_print_link]

This component is used to generate a print icon that opens the print dialog box for your particular browser. To generate this component, the `webhelp_print_link` element must be specified in the template file. It can be used in the following type of template page:

- ***Topic Template*** *(wt_topic.html file)*

In the template file, the `webhelp_print_link` element can be specified as in the following example:

```
<whc:webhelp_print_link
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_print_link`.

Include HTML files [webhelp_include_html]

This component can be used to include custom HTML files. To generate this component, the `include_html` element must be specified in the template file. It can be used in all four types of template pages:

- ***Main Page Template*** *(wt_index.html file)*
- ***Topic Template*** *(wt_topic.html file)*
- ***Search Results Template*** *(wt_search.html file)*
- ***Index Terms Template*** *(wt_terms.html file)*

In the template file, the `include_html` element can be specified as in the following example:

```
<whc:include_html href="${wh.param}"/>
```

Where the `href` can have the following values:

- **any URL** - In this case, the file to be included is specified as an URL.
- **{$oxygen-webhelp-template-dir}/file_to_include.html** - To include resources that are part of the template.
- **${webhelp.param}** - To include a resource whose path is specified through a WebHelp transformation scenario parameter. The value of this parameter can be a simple HTML fragment, in which case it will be copied to the output.

Index Terms Link [webhelp_indexterms_link]

This component can be used to generate a link to the index terms page (`indexterms.html`). If the published documentation does not contains any index terms, then the link will not be generated. To generate this component, the `webhelp_indexterms_link` element must be specified in the template file. It can be used in all four types of template pages:

- ***Main Page Template*** *(wt_index.html file)*
- ***Topic Template*** *(wt_topic.html file)*
- ***Search Results Template*** *(wt_search.html file)*
- ***Index Terms Template*** *(wt_terms.html file)*

In the template file, the `webhelp_indexterms_link` element can be specified as in the following example:

```
<whc:webhelp_indexterms_link
     xmlns:whc="http://www.oxygenxml.com/webhelp/components"/>
```

In the output, you will find an element with the class: `wh_indexterms_link`. This element will contain a link to the `indexterms.html` page.

Link to Skin Resources [webhelp_skin_resources]

This component can be used to add a link to resources for the current WebHelp skin (such as the CSS file). To generate this component, the `webhelp_skin_resources` element must be specified in the template file. It can be used in all four types of template pages:

- ***Main Page Template*** *(wt_index.html file)*
- ***Topic Template*** *(wt_topic.html file)*
- ***Search Results Template*** *(wt_search.html file)*
- ***Index Terms Template*** *(wt_terms.html file)*

In the template file, the `webhelp_skin_resources` element can be specified as in the following example:

```
<whc:webhelp_skin_resources/>
```

In the output, you will find a link to the skin resources.

Customizing the WebHelp Responsive Output

To change the overall appearance of your WebHelp Responsive output, you can use several different customization methods or a combination of methods. If you are familiar with CSS and coding, you can style your WebHelp output through your own custom stylesheets. You can also customize your output by modifying existing

templates, *create your own templates*, or by configuring certain options and parameters in the transformation scenario.

This section includes topics that explain various ways to customize your WebHelp Responsive system output, such as how to configure the tiles on the main page, add logos in the title area, integrate with social media, localizing the interface, and much more.

WebHelp Responsive Template Mechanism on page 1163
Context-Sensitive WebHelp Responsive System on page 1201

WebHelp Responsive Customization Methods

There are several methods that you can use to customize your WebHelp Responsive output. This topic provides information on each of the methods and highlights its advantages so that you can choose the best possible method based upon your needs.

Insert Custom XHTML Fragments in Predefined Placeholders

The WebHelp Responsive template contains a series of component placeholders. Some of these placeholders are left empty in the default output configurations, but you can use them to display custom content. This method is recommended if you want to use an existing skin and simply make some minor changes or additions in certain locations within the final output.

Advantages:

- This method is very easy, since the fragments for the placeholders can be specified in the transformation scenario.
- Advanced knowledge of CSS styling is not required for this method.

Each such placeholder has an associated parameter in the transformation scenario **Parameters** tab. These predefined empty placeholder parameters are illustrated and described below:

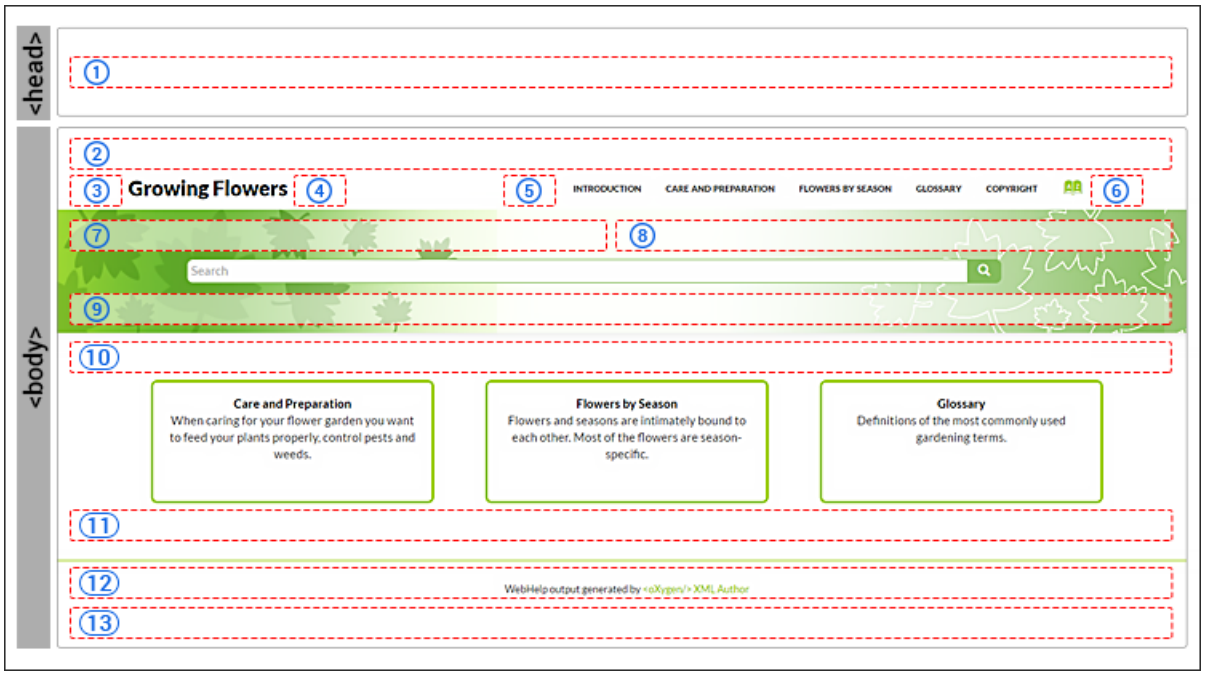

Figure 630: Predefined Placeholders Diagram

Each of these parameters can hold either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment:

1- webhelp.fragment.head

In the generated output it inserts a given XHTML fragment in the <head> element. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

2- webhelp.fragment.before.body

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

3- webhelp.fragment.before.logo_and_title

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

4- webhelp.fragment.after.logo_and_title

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

5- webhelp.fragment.before.top_menu

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

6- webhelp.fragment.after.top_menu

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

7- webhelp.fragment.before.main.page.search

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

8- webhelp.fragment.welcome

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

9- webhelp.fragment.after.main.page.search

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

10- webhelp.fragment.before.toc_or_tiles

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

11- webhelp.fragment.after.toc_or_tiles

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

12- webhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

13- webhelp.fragment.after.body

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

EXAMPLE:

To insert a message above the search field component in the main page of the output, follow this procedure:

1. Edit the **WebHelp Responsive** transformation scenario.
2. Go to **Parameters** tab and find the parameter associated with the place holder that you want to use. In this case, it is called `webhelp.fragment.welcome`.
3. Edit the parameter. Depending on the size of the content you want to add, you can insert one of the following:
   - A small well-formed XHTML fragment, such as: `<i>Welcome to our user guide</i>`.
   - A path to a file that contains well-formed XHTML content.

Customize WebHelp Output with a Custom CSS

This method is recommended if you just want to adapt an existing skin (that is very close to what you need) and only need to change the styling of the final output. For example, this might be the case if you simply want to change a color, or adjust some of the margins or paddings of certain components.

Advantages:

- This method could be used as a quick and easy way to make small styling changes.
- The custom CSS can be distributed with your project and shared with other members of your team.
- This method can be used for advanced and precise styling.

Additional Notes:

- The fonts, images, and other resources must be stored in a remote server location.
- This type of customization will not appear in the `Templates` tab of the transformation scenario. Instead, the custom CSS needs to be set as a parameter of an existing transformation scenario.

To set a custom CSS to a transformation scenario:

1. Edit the **WebHelp Responsive** transformation scenario.
2. Open the **Parameters** tab.
3. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed. Also, if your customization CSS requires additional resources, you can copy them to the generated output by specifying the *webhelp.custom.resources parameter*.

If you are using DITA, you could also override the default XSLT templates that are used for WebHelp transformations by using some extension points. For information about this method, see *Overriding XSLT Processing Step of DITA WebHelp Classic Transformations* on page 1229.

Create or Customize a WebHelp Responsive Skin

This method is recommended if you want a design that is not similar to any of the predefined skins, or if you want to make a lot of changes to one of the existing skins. This method is also useful if you want to distribute additional resources (such as fonts and images) together with a custom CSS.

Advantages:

- The customized skin will be available in the **Templates** tab of the transformation scenario.
- The resources are encapsulated into the `skin` directory and can be shared with other team members, along with a custom CSS file.

Additional Notes:

- This method requires access to the installation folder, or the use of an external DITA-OT engine (with the *WebHelp plugin* installed).

To create a new WebHelp Responsive skin, follow this procedure:

1. Locate the following folder in your DITA-OT directory (*DITA-OT-DIR*):

   ```
   DITA-OT-DIR/plugins/com.oxygenxml.webhelp/templates/dita/bootstrap/variants/
   ```

2. Here you can see some subdirectories corresponding to different variants for the same template. For instance, the default directories are `tiles` and `tree`.
3. In each of these variants, you will find a directory for each of the skins (for example, the default skins and their corresponding directories are: *flowers*, *green*, *light*, *mechano*, *orange*, etc.)
4. Duplicate one of the skin folders and rename it to whatever you want your new skin to be identified as.
5. Edit the `skin.css` file and customize it the way you want. If your customization of the CSS file requires additional resources (such as images, fonts, or other CSS files), they need to be placed in the `resources` folder at the same level with the `skin.css` file.

   Result: Your new skin should now be included in the list of skins in the **Templates** tab of the transformation scenario.

Tip: During development, you may want to regularly test your customization. To shorten the publishing time of your tests, use a small set of test files (you could use one of the Oxygen XML Editor sample projects). Also, you can use your web browser CSS inspector tool to lookup the CSS classes you want to modify.

Create a New WebHelp Responsive Template

This method can be used when you need to make significant structural changes to the WebHelp output. For example, if you want to move some components to other positions, or if you want to use a different responsive front-end *framework* than the default *Bootstrap framework* (for instance, if you want to switch to *ZURB Foundation*).

Advantages:

- This method allows you to fully customize the output.
- This method allows you to *change the structure of the generated HTML files*.
- You can *create your own skins* for the new template.

Additional Notes:

- This method requires access to the installation folder, or the use of an external DITA-OT engine (with the *WebHelp plugin* installed).

To create a new WebHelp Responsive template, follow these steps:

1. Locate the following folder in your DITA-OT directory (*DITA-OT-DIR*):

   ```
   DITA-OT-DIR/plugins/com.oxygenxml.webhelp/templates/dita/
   ```

2. Duplicate the `bootstrap` folder and rename it to whatever you want your new template to be identified as (for example, `myTemplate`).
3. Customize the structure of the new template according to your needs. For example, if you only want to keep one of the template variants, open the `myTemplate/variants` folder and delete all of its subdirectories, except for that one (for instance, the `tiles` directory). Keep in mind that the structure of the template directory is important. The names of folders at certain levels correspond to the names of templates and skins, while components and resources are defined and referenced in certain files or folders at specific locations within the directory structure. For more information, see *WebHelp Responsive Template Directory Structure* on page 1164.
4. You can also customize the structure of the skins within the template variants. For example, if you only want to keep one of the skins in the `tiles` variant, open the `myTemplate/variants/tiles` folder and delete all of its subdirectory skins, except for that one (for instance, the `light` directory).
5. Edit the `skin.css` file that is located in the skin directory (for example, `myTemplate/variants/tiles/light`) and customize it the way you want. If your customization of the CSS file requires additional resources (such as images, fonts, or other CSS files), they need to be placed in the `resources` folder at the same level with the `skin.css` file.

   Result: Your new templates and skins should now be included in the **Templates** tab of the transformation scenario.

Tip: During development you regularly need to test your customization. To shorten the publishing time of your test, use a small project (you could use one of the Oxygen XML Editor sample projects). Also, you can use your web browser CSS inspector tool to lookup the CSS classes you want to modify.

For more information about WebHelp Responsive templates, see the *WebHelp Responsive Template Mechanism* on page 1163 section.

Copying Additional Resources to WebHelp Output Directory

To copy additional resources (such as JavaScript, CSS or other resources) to the output directory of a WebHelp system, follow these steps:

1. Place all your resources in the same directory.
2. Edit the WebHelp transformation scenario.
3. Go to the **Parameters** tab.

4. Edit the value for the webhelp.custom.resources parameter and set it to the absolute path of the directory in step 1.
5. Click **OK** to save the changes to the transformation scenario.
   All files from the new directory will be copied to the root of the WebHelp output directory.

Adding Custom HTML Content in WebHelp Responsive Output

You can add custom HTML content in the WebHelp Responsive output by inserting it in a well-formed XML file that will be referenced in the transformation scenario. This content may include references to additional JavaScript, CSS, and other types of resources, or such resources can be inserted inline within the HTML content that is inserted in the XML file.

To include custom HTML content in the WebHelp Responsive output files, follow these steps:

1. Insert the HTML content in a well-formed XML file. There are several things to consider in regards to this XML file:
   a. **Well-Formedness** - If the file is not a *Well-formed XML document* (or fragments are not well-formed), the transformation will fail.

      A common use case is if you want to include several `script` or `link` elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in an `html` element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `head`, `body`, `html/head`, or `html/body` elements.
   b. **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the predefined `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

      ```
      <html>
        <script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"/>
        <link rel="stylesheet" type="text/css"
              href="${oxygen-webhelp-output-dir}/css/test.css" />
      </html>
      ```

      If you want that the path of your resource to be relative to the *templates directory*, you can use the `${oxygen-webhelp-template-dir}` macro.

      To copy the referenced resources to the output directory, follow the procedure in: *Copying Additional Resources to WebHelp Output Directory* on page 1179.
   c. **Inline JavaScript or CSS Content** - If you want to include inline JavaScript or CSS content in the XML file, it is important to place this content inside an XML comment, as in the following examples:

      JavaScript:

      ```
      <script type="text/javascript">
        <!--
          /* Include JavaScript code here. */

          function myFunction() {
            return true;
          }
        -->
      </script>
      ```

      CSS:

      ```
      <style>
        <!--
          /* Include CSS style rules here. */

          *{
            color:red
          }
        -->
      </style>
      ```
2. Edit the WebHelp Responsive transformation scenario.
3. Go to the **Parameters** tab.
4. Edit the value of the *webhelp.fragment.head parameter* and set it to the absolute path of the XML file created in step 1. Your additional content will be included at the end of the `head` element of your output document.

Note: If you want to insert the content in another location within the output document, you can reference the XML file in any of the other parameters listed in *Insert Custom XHTML Fragments in Predefined Placeholders* on page 1176.

5. Click **OK** to save the changes to the transformation scenario.

Related Information:

Copying Additional Resources to WebHelp Output Directory on page 1179

WebHelp Responsive Template Directory Structure on page 1164

WebHelp Responsive Customization Methods on page 1176

Adding an Edit Link to Launch Oxygen XML Web Author

You can embed *Edit* links in the DITA WebHelp Responsive output that will automatically launch a particular document in *Oxygen XML Web Author*. A reviewer can then simply click the link and they will be redirected to the Oxygen XML Web Author editing page with that particular file open and editable.

To embed an *Edit* link in the DITA Map WebHelp Responsive output, follow these steps:

1. *Edit a **DITA Map WebHelp Responsive** transformation scenario* and open the **Parameters** tab.
2. Set values for the following parameters:
   - **editlink.remote.ditamap.url** - The URL of the DITA Map suitable for opening in Oxygen XML Web Author.
   - **editlink.web.author.url** - The URL of the Oxygen XML Web Author installation.
3. Run the transformation scenario.

Result: In the WebHelp output, all topics will have an **Edit** link to the right side of the title and clicking the link will launch that particular document in Oxygen XML Web Author.

Adding a Favicon in WebHelp Systems

You can add a custom *favicon* to your WebHelp system by simply using a parameter in the transformation scenario to point to your *favicon* image. This is available for DITA and DocBook WebHelp systems using **WebHelp Responsive**, **WebHelp Responsive with Feedback**, **WebHelp Classic**, **WebHelp Classic with Feedback**, or **WebHelp Classic Mobile** transformation scenarios.

To add a *favicon*, follow these steps:

1. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
2. Locate the `webhelp.favicon` parameter and enter the file path that points to the image that will be use as the *favicon*.
3. Run the transformation scenario.

Adding a Logo Image in the Title Area

To add a logo in the title area of your WebHelp output, follow this procedure:

1. Edit a WebHelp transformation scenario, then open the **Parameters** tab.
2. Specify the path to your logo in the `webhelp.logo.image` parameter.
3. If you also want to add a link to your website when you click the logo image, set the URL in the `webhelp.logo.image.target.url` parameter.
4. Run the transformation scenario.

Adding a Welcome Message in the Home Page

The main page of the WebHelp Responsive output contains a set of empty placeholders that can be used to display customized text fragments. These placeholders are available to you through *WebHelp Responsive transformation scenario parameters*. One of these placeholders (identified through the `webhelp.fragment.welcome` parameter) was designed to display text content above the search box in the main page.

To add a customized welcome message in the main page of the WebHelp Responsive output, follow this procedure:

1. Edit a WebHelp Responsive transformation scenario.
2. Open the ***Templates** tab* and choose a *skin*.

3. Open the ***Parameters** tab* and edit the `webhelp.fragment.welcome` parameter. The value of this parameter can be one of the following:
   - A small well-formed XHTML fragment (such as: `<i>Welcome to the User Guide</i>`).
   - Path to a file that contains well-formed XHTML content.
4. Click **OK**, then click the **Apply associated** button to execute the transformation scenario.

Adding Video and Audio Objects in DITA WebHelp Output

You can insert references to video and audio media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics and then publish them to WebHelp output. The media objects can be played directly in all HTML5-based outputs, including WebHelp systems.

To add media objects in the WebHelp output generated from DITA documents, follow the procedures below.

Adding Videos to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the video through one of the following methods:
   - Use the ***Insert Media Object** toolbar action*.
   - Drag (or copy) the video file from your system explorer or the ***Project** view* and drop (or paste) it into your document.
   - Manually add an `object` element, as in one of the following examples:

     ```
     <object outputclass="video" type="video/mp4" data="MyVideo.mp4"/>
     ```

     or, instead of the `data` attribute, you can specify the video using a parameter like this:

     ```
     <object outputclass="video">
       <param name="src" value="videos/MyVideo.mp4"/>
     </object>
     ```
2. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

   Result: The transformation converts the `object` element to an HTML5 `video` element.

   ```
   <video controls="controls"><source type="video/mp4" src="MyVideo.mp4"></source>
   </video>
   ```

Adding Audio Clips to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the audio clip through one of the following methods:
   - Use the ***Insert Media Object** toolbar action*.
   - Drag (or copy) the audio file from your system explorer or the ***Project** view* and drop (or paste) it into your document.
   - Manually add an `object` element, as in one of the following examples:

     ```
     <object outputclass="audio" type="audio/mpeg" data="MyClip.mp3"/>
     ```

     or, instead of the `data` attribute, you can specify the video using a parameter like this:

     ```
     <object outputclass="audio">
       <param name="src" value="audio/MyClip.mp3"/>
     </object>
     ```
2. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

   Result: The transformation converts the `object` element to an HTML5 `audio` element.

   ```
   <audio controls="controls"><source type="audio/mpeg" src="MyClip.mp3"></source>
   </audio>
   ```

Adding Embedded HTML Frames (such as YouTube videos) to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the embedded object by using the  ***Insert Media Object*** *toolbar action* or by manually adding an `object` element, as in one of the following examples:

   ```
   <object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
   ```

   or, instead of the `data` attribute, you can specify the object using a parameter like this:

   ```
   <object outputclass="iframe">
     <param name="src" value="http://www.youtube.com/embed/m_vv2s5Trn4"/>
   </object>
   ```

2. If you want the video to be allowed to play in full screen mode once the document is converted to XHTML output, also add an `allowfullscreen` parameter and set its value to **true**:

   ```
   <object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
     <param name="allowfullscreen" value="true"/>
   </object>
   ```

   Tip: If you copy the embed code from the source and paste it into the **Insert Media** dialog box (see the specific instructions: *here*), the `allowfullscreen` parameter will automatically be added and all you have to do is set the value to **true**.

3. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

   Result: The transformation converts the `object` element to an HTML5 `iframe` element.

   ```
   <iframe controls="controls" src="https://www.youtube.com/embed/m_vv2s5Trn4">
   </iframe>
   ```

For more information, see the following video demonstration:

Adding Video, Audio, and Embedded HTML Resources in DITA Topics on page 1830

Configuring the Tiles on the Main Page

The *tiles* version of the main page of the WebHelp Responsive output displays a tile for each topic found on the first level of the *DITA map*. However, you might want to customize the way they look or even to hide some of them.

Depending on your particular setup, you can choose to customize the these tiles either by setting metadata information in the *DITA map* or by customizing the CSS that is associated with the *DITA map*.

How to Hide Some of the Tiles

If your documentation is very large or there is a large number of topics on the first level, you might want to hide some of the tiles. Also, this might be useful if you only want to display the topics in the first page that are most relevant to your intended audience.

There are two methods for doing this. One of them involves editing the *DITA map* and marking the topics that do not need to be displayed as tiles, and another one that uses a small CSS customization level to hide some tiles identified by the ID of the topic.

Editing the DITA Map

To edit the metadata in the *DITA map* to control which topics on the first level of the *DITA map* will not be displayed as a tile, follow these steps:

1. Open the *DITA map* in the **Text** editing mode of Oxygen XML Editor.
2. Add the following metadata information in the `topicref` element (or any of its specializations) for each first-level topic that you do not want to be displayed as a tile:

   ```
   <topicmeta>
     <data name="wh-tile">
       <data name="hide" value="yes"/>
     </data>
   </topicmeta>
   ```

Customizing the CSS

To customize the CSS to control which topics on the first level of the *DITA map* will not be displayed as a tile, follow these steps:

1. Make sure you set an ID on the topic you want to hide.
2. Create a new CSS file that contains a rule that hides the tile generated for the topic (identified in the following example by the topic ID `growing-flowers`). The CSS file should have content that is similar to this:

```
.wh_tile [data-id='growing-flowers'] {
  display:none;
}
```

3. Use the *Customizing WebHelp Output with a Custom CSS* method to pass the CSS file you just created to the transformation scenario.

How to Add an Image to the Tiles

There are two methods that you can use to add an image to a tile. One of them involves editing the *DITA map*, and the other uses a CSS customization.

Editing the DITA Map

To edit the metadata in the *DITA map* to set an image to be displayed in a tile, follow these steps:

1. Open the *DITA map* in the **Text** editing mode of Oxygen XML Editor.
2. Add the following metadata information in the `topicref` element (or any of its specializations) for each first-level topic that will have an image displayed in the corresponding tile:

```
<topicmeta>
  <data name="wh-tile">
    <data name="image" href="img/tile-image.png" format="png">
     <data name="attr-width" value="64"/>
     <data name="attr-height" value="64"/>
    </data>
  </data>
</topicmeta>
```

Note: The `attr-width` and `attr-height` attributes can be used to control the size of the image, but they are optional.

Customizing the CSS

To customize the CSS to set an image to be displayed in a tile, follow these steps:

1. Make sure you set an ID on the topic that you want the tile include an image.
2. Create a new CSS file that contains a rule that associates an image with a specific tile. The CSS file should have content that is similar to this:

```
.wh_tile[data-id='growing-flowers']> div {
    background-image:url('resources/flower.png');
}
```

3. Use the *Customizing WebHelp Output with a Custom CSS* or the *Create a WebHelp Responsive Skin* method to pass the CSS file you just created to the transformation scenario.

Change Numbering Styles for Ordered Lists

Ordered lists (`ol`) are usually numbered in XHTML output using numerals. If you want to change the numbering to alphabetical, follow these steps:

1. Define a custom `outputclass` value and set it as an attribute of the ordered list, as in the following example:

```
<ol outputclass="number-alpha">
    <li>A</li>
    <li>B</li>
    <li>C</li>
</ol>
```

2. Add the following code snippet in a custom CSS file:

```
ol.number-alpha{
    list-style-type:lower-alpha;
```

```
}
```

3. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
4. Run the transformation scenario.

CSS Styling to Customize WebHelp Output

One way to customize WebHelp output is to use custom CSS styling. This method can be used to make small, simple styling changes or more advanced, precise changes. To implement the styling in your WebHelp output, you simply need to create the custom CSS file and reference it in your transformation scenario. This custom file will be the final CSS to be applied so its content will override the styles in the other pre-existing CSS files.

Using CSS Inspector to Identify Content for Custom CSS File

You can use your browser's CSS inspector to identify the pertinent code in the current CSS files and you can even make changes directly in the CSS inspector to test the results so that you know exactly what content to use in your custom CSS file.

In most popular browsers (such as Chrome, Firefox, and Edge), you can access the CSS inspector by using **F12** or by selecting **Inspect Element** (or simply **Inspect**) from the contextual menu. When using Safari on Mac OS X, you must first enable the Develop menu by going to the Advanced settings and selecting **Show Develop menu in menu bar**. Then you can select **Show Web Inspector** from the Develop menu or click **Command+Option+I**.

Example: How to Change the Background Color of the Footer Bar

As a practical example, the following procedure can be used to change the background color of the footer bar in the WebHelp output of the Oxygen XML Editor User Guide:

1. Use the browser's CSS inspector to identify the current CSS code that styles the footer bar. In this particular case, the pertinent code that would be identified is:

```
.wh_footer {
  font-size: 15px;
  line-height: 1.7em;
  background-color: #000;
}
```

2. If you want to test the color you want to apply as the background of this particular element, use the browser's CSS inspector to change the value of the `background-color` attribute. After you find a suitable color, copy that new code.
3. Create a custom CSS file and paste or enter the copied code. For example:

```
.wh_footer {
  background-color: #255890;
}
```

4. Save the custom CSS file at a location of your convenience.
5. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
6. Run the transformation scenario.

Result: Your custom CSS snippet will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

Customizing the Menu

By default, the menu component is displayed in all WebHelp Responsive pages. However, you might want to hide it completely, or only display some of its menu entries.

How to Hide Some of the Menu Entries

There are two methods for doing this. One of them involves editing the *DITA map* and marking the topics that do not need to be included in the menu, and another one that uses a small CSS customization.

Editing the DITA Map

To edit the metadata in the *DITA map* to control which topics will not be displayed in the menu, follow these steps:

1. Open the *DITA map* in the **Text** editing mode of Oxygen XML Editor.
2. Add the following metadata information in the `topicref` element (or any of its specializations) for each topic you do not want to be displayed in the menu:

```
<topicmeta>
  <data name="wh-menu">
    <data name="hide" value="yes"/>
  </data>
</topicmeta>
```

Customizing the CSS

To customize the CSS to control which topics will not be displayed in the menu, follow these steps:

1. Make sure you set an ID on the topic that you do not want to include in the menu.
2. Create a new CSS file that contains a rule that hides the menu entry generated for the topic (identified by the topic ID `growing-flowers` in the following example). The CSS file should have content that is similar to this:

```
.wh_top_menu *[data-id='growing-flowers'] {
  display:none;
}
```

3. Use the *Customizing WebHelp Output with a Custom CSS* method to pass the CSS file you just created to the transformation scenario.

How to Hide the Entire Menu

If you do not want to include a main menu in the pages of the WebHelp Responsive output, you can instruct the transformation scenario to skip the menu generation completely. To do so, follow this procedure:

1. Edit a WebHelp Responsive transformation scenario.
2. Open the ***Templates** tab* and choose a *skin*.
3. Open the ***Parameters** tab* and set the value of the `webhelp.show.top.menu` parameter to no.
4. Click **OK**, then click the **Apply associated** button to execute the transformation scenario.

Editing Scoring Values of Tag Elements in Search Results

The WebHelp **Search** feature is enhanced with a rating mechanism that computes scores for every page that matches the search criteria. HTML tag elements are assigned a scoring value and these values are evaluated for the search results. Oxygen XML Editor includes a properties file that defines the scoring values for tag elements and this file can be edited to customize the values according to your needs.

To edit the scoring values of HTML tag element for enhancing WebHelp search results, follow these steps:

1. Edit the scoring properties file for DITA or DocBook WebHelp systems. The properties file includes instructions and examples to help you with your customization.
   a) For DITA WebHelp systems, edit the following file: *`DITA-OT-DIR`*`\plugins\com.oxygenxml.webhelp\indexer\scoring.properties`.
   b) For DocBook WebHelp system, edit the following file: *`[OXYGEN_INSTALL_DIR]`*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\indexer\scoring.properties`.

   The values that can be edited in the `scoring.properties` file:

```
h1 = 10
h2 = 9
h3 = 8
h4 = 7
h5 = 6
h6 = 5
b = 5
strong = 5
em = 3
i=3
```

```
u=3
div.toc=-10
title=20
div.ignore=ignored
meta_keywords = 20
meta_indexterms = 20
meta_description = 25
shortdesc=25
```

2. Save your changes to the file.
3. Re-run your WebHelp system transformation scenario.

Exclude Certain DITA Topics from WebHelp Search Results

There are several ways to exclude certain DITA resources from your WebHelp system's search results. This is useful if you have topics in your *DITA map* structure that you do not want to be included in search results for your WebHelp system. The first method involves setting a parameter in the WebHelp transformation scenario and the second involves setting an attribute for each DITA topic reference that you want to exclude.

Transformation Parameter Method

To exclude DITA topics from WebHelp search results using a transformation parameter, follow these steps:

1. Create a simple text file that will contain your excluded file patterns. Each pattern must be on a new line. The patterns are considered to be relative to the output directory and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

   Example: Suppose that in your project, you want to exclude all files located in the `resources` directory and all files located in the `topics` directory that have a `.bak` file extension. You could create a simple text file (for example, named `exclude.properties`), and add the following lines:

   ```
   resources/*
   topics/*.bak
   ```

2. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
3. Set the `webhelp.search.custom.excludes.file` parameter to specify the path to the file that contains the excluded file patterns (for example, `exclude.properties` in step 1).
4. Run the transformation scenario.

Search Attribute Method

The WebHelp **Search** engine does not index DITA topics that have the `@search` attribute set to no.

To exclude DITA topics from WebHelp search results using this attribute, follow these steps:

1. Edit the *DITA map* and for any `topicref` that you want to exclude from search results, set the `search` attribute to no.

   For example:

   ```
   <topicref href="../topics/internal-topic1.dita" search="no"/>
   ```

2. Save your changes to the *DITA map*.
3. Run your WebHelp system transformation scenario.

Flag DITA Content in WebHelp Output

Flagging content in WebHelp output involves defining a set of images that will be used for marking content across your information set.

To flag DITA content, you need to create a filter file that defines properties that will be applied on elements to be flagged. Generally, flagging is supported for *block elements* (such as paragraphs), but not for phrase-level elements within a paragraph. This ensures that the images that will flag the content are easily scanned by the reader, instead of being buried in text.

Follow this procedure:

1. Create a DITA filter file in the directory where you want to add the file. Give the file a descriptive name, such as `audience-flag-build.ditaval`.

2. Define the property of the element you want to be flagged. For example, if you want to flag elements that have the `audience` attribute set to `programmer`, the content of the DITAVAL file should look like the following example:

```
<?xml version="1.0" encoding="UTF-8"?>
<val>
  <prop att="audience" val="programmer" action="flag"
 img="D:\resource\delta.gif" alt="sample alt text"/>
</val>
```

   Note that for an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.
3. Specify the DITAVAL file in the **Filters** tab of the transformation scenario.
4. Run the transformation scenario.

Integrating Social Media and Google Tools in WebHelp Output

Oxygen XML Editor includes support for integrating some of the most popular social media sites in WebHelp output.

How to Add a Facebook Like Button in WebHelp Responsive Output

To add a Facebook™ *Like* widget to your WebHelp output, follow these steps:

1. Go to the *Facebook Developers* website.
2. Fill-in the displayed form, then click the **Get Code** button.
   A dialog box that contains code snippets is displayed.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`.

   Make sure you follow these rules:

   - The file must be well-formed.
   - The code for each `script` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

```
<div id="facebook">
    <div id="fb-root"/>
    <script>
        <!--
            (function(d, s, id) {
        var js, fjs = d.getElementsByTagName(s)[0];
        if (d.getElementById(id)) return;
        js = d.createElement(s); js.id = id;
        js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
        fjs.parentNode.insertBefore(js, fjs);
        }(document, 'script', 'facebook-jssdk'));
        -->
    </script>
    <div class="fb-like" data-layout="standard" data-action="like"
        data-show-faces="true" data-share="true"/>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab. Depending on where you want to display the button, edit *one of the parameters that begin with webhelp.fragment*. Set that parameter to reference the `facebook-widget.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Add a Google+ Button in WebHelp Responsive Output

To add a *Google+* widget to your WebHelp Responsive output, follow these steps:

1. Go to the *Google Developers* website.

2. Fill-in the displayed form.
   The preview area on the right side displays the code and a preview of the widget.
3. Copy the code snippet displayed in the preview area and paste it into a `div` element inside an XML file called `google-plus-button.xml`.

   Make sure that the content of the file is well-formed.

   The content of the XML file should look like this:

```
<div id="google-plus">
  <!-- Place this tag in your head or just before your close body tag. -->
  <script src="https://apis.google.com/js/platform.js" async defer></script>

  <!-- Place this tag where you want the +1 button to render. -->
  <div class="g-plusone" data-annotation="inline" data-width="300"></div>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab. Depending on where you want to display the button, edit *one of the parameters that begin with webhelp.fragment*. Set that parameter to reference the `google-plus-button.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Add Tweet Button in WebHelp Responsive Output

To add a Twitter™ *Tweet* widget to your WebHelp Responsive output, follow these steps:

1. Go to the *Tweet button generator* page.
2. Fill-in the displayed form.
   The **Preview and code** area displays the code.
3. Copy the code snippet displayed in the **Preview and code** area and paste it into a `div` element inside an XML file called `tweet-button.xml`.

   Make sure you follow these rules:

   - The file must be well-formed.
   - The code for each `script` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

```
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
    <!--
      !function (d, s, id) {
      var
      js, fjs = d.getElementsByTagName(s)[0], p = /^http:/.test(d.location)
 ? 'http': 'https';
      if (! d.getElementById(id)) {
      js = d.createElement(s);
      js.id = id;
      js.src = p + '://platform.twitter.com/widgets.js';
      fjs.parentNode.insertBefore(js, fjs);
      }
      }
      (document,
      'script', 'twitter-wjs');
     -->
  </script>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.

5. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab. Depending on where you want to display the button, edit *one of the parameters that begin with webhelp.fragment*. Set that parameter to reference the `tweet-button.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Integrate Google Analytics in WebHelp Responsive Output

To allow your WebHelp Responsive system to benefit from Google Analytics reports, follow these steps:

1. Create a new Google Analytics account (if you do not already have one) and log on.
2. Choose the Analytics solution that fits the needs of your website.
3. Follow the on-screen instructions to obtain a **Tracking Code** that contains your *Tracking ID*.

   A **Tracking Code** looks like this:

```
<script>
 (function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
 (i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
 m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
 })(window,document,'script','//www.google-analytics.com/analytics.js','ga');

 ga('create', 'UA-XXXXXXXX-X', 'auto');
 ga('send', 'pageview');
</script>
```

4. Save the Tracking Code (obtained in the previous step) in a new HTML file called `googleAnalytics.html`.
5. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
6. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
7. Switch to the **Parameters** tab. Depending on where you want to display the button, edit *one of the parameters that begin with webhelp.fragment*. Set that parameter to reference the `googleAnalytics.html` file that you created earlier.
8. Click **Ok**.
9. Run the transformation scenario.

How to Integrate Google Search in WebHelp Responsive Output

You can integrate Google Search into your WebHelp Responsive output.

To allow your WebHelp system to use Google Search, follow these steps:

1. Go to the Google Custom Search Engine page using your Google account.
2. Press the **Create a custom search engine** button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet.

   A Google Search script looks like this:

```
<script>
 (function()  {
  var cx =
    '000888210889775888983:8mn4x_mf-yg';
  var gcse = document.createElement('script');
  gcse.type = 'text/javascript';
  gcse.async = true;
  gcse.src = (document.location.protocol == 'https:' ?
    'https:' : 'http:') +         '//www.google.com/cse/cse.js?cx=' + cx;
  var s = document.getElementsByTagName('script')[0];
```

```
  s.parentNode.insertBefore(gcse, s);
 }
 )();
</script>
```

4. Save the script into a well-formed HTML file called `googlecse.html`.
5. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
6. Select an existing WebHelp Responsive transformation scenario (depending on your needs, it may be with or without feedback) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
7. Switch to the **Parameters** tab and edit the `webhelp.google.search.script` parameter to reference the `googlecse.html` file that you created earlier.
8. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a) Create an HTML file with the following content: `<div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName-"searchQuery"></div>` (you must use the *HTML5 version for the GCSE*). For more information about other supported attributes, see *Google Custom Search: Supported Attributes*.
   b) Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used: `<div class="gcse-searchresults-only" data-autoSearchOnLoad="true" data-queryParameterName="searchQuery"></div>`.
9. Click **Ok**.
10. Run the transformation scenario.

Integrating Social Media and Google Tools in WebHelp Output on page 1188

Localizing the Email Notifications of WebHelp with Feedback Systems

The feedback-enabled WebHelp systems use emails to notify users when comments are posted. These emails are based on templates stored in the WebHelp directory. The default messages are in English, French, German, and Japanese. These messages are copied into the WebHelp system deployment directory during the execution of the corresponding transformation scenario.

Suppose that you want to localize the emails into Dutch (*nl*). Follow these steps:

DocBook WebHelp Classic with Feedback

1. Create the following directory:

   [OXYGEN_INSTALL_DIR]`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl`
2. Copy all English template files from *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\en` and paste them into the directory you just created.
3. Edit the HTML files from the *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl` directory and translate the content into Dutch.
4. Start Oxygen XML Editor and edit the **DocBook WebHelp Classic with Feedback** transformation scenario.
5. In the **Parameters** tab, look for the `l10n.gentext.default.language` parameter and set its value to the appropriate language code. In our example, use the value `nl` for Dutch.

   Note: If you set the parameter to a value such as `LanguageCode-CountryCode` (for example, `en-us`), the transformation scenario will only use the language code
6. Run the transformation scenario to obtain the **WebHelp with Feedback** output.

DITA WebHelp Classic with Feedback or WebHelp Responsive with Feedback

1. Create the following directory:

DITA-OT-DIR\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl

2. Copy all English template files from *DITA-OT-DIR*\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\en and paste them into the directory you just created.
3. Edit the HTML files from the *DITA-OT-DIR*\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl directory and translate the content into Dutch.
4. Start Oxygen XML Editor and edit the **DITA Map WebHelp Classic with Feedback** or **DITA Map WebHelp Responsive with Feedback** transformation scenario.
5. In the **Parameters** tab, look for the `args.default.language` parameter and set its value to the appropriate language code. In our example, use the value `nl` for Dutch.

   Note: If you set the parameter to a value such as `LanguageCode-CountryCode` (for example, `en-us`), the transformation scenario will only use the language code
6. Run the transformation scenario to obtain the **WebHelp with Feedback** output.

Localizing the Interface of WebHelp Output (for DITA Map Transformations)

Static labels used in the WebHelp output are stored in translation files that have the *strings-lang1-lang2.xml* name format, where *lang1* and *lang2* are ISO language codes. For example, the US English labels are kept in the *strings-en-us.xml* file.

These translation files are collected from two locations:

- `DITA-OT_DIR/xsl/common` folder - DITA-OT's default translations.
- *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder - These translations are contributed by the WebHelp plugin and extend the default ones provided by DITA-OT. The labels defined in this folder take precedence over the DITA-OT default ones.

  Important: If you need to customize the translation labels, you should do this by updating the translation files found in the *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder.

To localize the interface of the WebHelp output for *DITA map* transformations, follow these steps:

1. Look for the *strings-[lang1]-[lang2].xml* file in *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory (for example, the Canadian French file would be: *strings-fr-ca.xml*). If it does not exist, use the following procedure to create one:
   a) Create a new `strings-fr-ca.xml` file in the *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory.
   b) Copy all the labels found in the *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings-en-us.xml` and paste them into the newly created file.
   c) Copy all the labels found in the `DITA-OT_DIR/xsl/common/strings-en-us.xml` and paste them into the newly created file.
2. Translate all the labels from the above language file. Labels are stored in XML elements that have the following format: `<str name="Label name">Caption</str>`.
3. Run the predefined transformation scenario called **Run DITA OT Integrator** by executing it from the  **Apply Transformation Scenario(s)** dialog box. If the *integrator* is not visible, select the **Show all scenarios** action that is available in the  **Settings** drop-down menu.
4. Make sure that the new XML file that you created in the previous two steps is listed in the file *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings.xml`. In our example for the Canadian French file, it should be listed as: `<lang xml:lang="fr-ca" filename="strings-fr-ca.xml"/>`.
5. Edit any of the **DITA Map to WebHelp** transformation scenarios (with or without feedback, or the mobile version) and set the args.default.language parameter to the code of the language you want to localize (for example, *fr-ca* for Canadian French).
6. Run the transformation scenario to produce the WebHelp output.

Related Information:

Searching Japanese Content in WebHelp Pages on page 1193

Searching Japanese Content in WebHelp Pages

To optimize the indexing of Japanese content in WebHelp pages, the Lucene Kuromoji Japanese analyzer can be used. This analyzer is included in the Oxygen XML Editor installation kit.

Activating Japanese Indexing in DITA WebHelp Systems

To activate the Japanese indexing in your WebHelp system generated from DITA content, follow these steps:

1. Set the language for your content to Japanese with one of the following two methods:
   - Edit a **DITA to WebHelp** transformation scenario and in the ***Parameters*** *tab*, set the value of the `args.default.language` parameter to `ja-jp`.
   - Set the `xml:lang` attribute on the root of the *DITA map* and the referenced topics to `ja-jp`.
2. For the analyzer to work properly, search terms that are entered into the WebHelp search text field must be separated by spaces.
3. Run the **DITA to WebHelp** transformation scenario to generate the output.

Optionally a Japanese user dictionary can be set with the *webhelp.search.japanese.dictionary parameter*.

Activating Japanese Indexing in DocBook WebHelp Systems

To activate the Japanese indexing in your WebHelp system generated from DocBook content, follow these steps:

1. Edit a **DocBook to WebHelp** transformation scenario and in the ***Parameters*** *tab*, set the value of the `l10n.gentext.default.language` parameter to `ja`.
2. Run the transformation scenario to generate the output.

Overriding XSLT Processing Step of DITA WebHelp Responsive Transformations

Since WebHelp Responsive output is primarily obtained by running XSLT transformations over the DITA input files (through the **DITA Map WebHelp Responsive** transformation scenarios), one customization method would be to override the default XSLT templates that are used by the WebHelp Responsive transformations.

There are two methods available to override the XSLT stylesheets implied by the WebHelp Responsive transformation.

- The first method is to use one of the ***WebHelp Responsive XSLT-import extension points*** that allow you to import an XSLT stylesheet so that it becomes part of the normal build. This method uses the same mechanism as the *DITA-OT XSLT-import extension points*. Note that this method will affect all the outputs generated with the WebHelp system.
- The second method implies that you will *create a DITA-OT extension plugin* with a custom *transtype* and use an Ant build file to define the transformation process. The main difference from the first customization method is that you will not affect all WebHelp Responsive transformations. Only the transformations that use the declared plugin *transtype* will be affected.

WebHelp Responsive XSLT-Import and XSLT-Parameter Extension Points

The WebHelp Responsive XSLT-Import extension points allows you to extend the XSLT stylesheets associated with some of the WebHelp Responsive transformation steps. The DITA-OT plug-in installer adds an XSLT import statement in the default WebHelp XSLT so that the XSLT stylesheet referenced by the extension point becomes part of the normal build.

Example:

```
<plugin id="com.oxygenxml.webhelp.responsive.extension">
  <feature extension="com.oxygenxml.webhelp.responsive.xsl.dita2webhelp"
           file="xsl/fixup.xsl"/>
```

```
</plugin>
```

Attention: The customizations you make by using this extension point will affect all WebHelp Responsive transformations. If you want to have a customization that is only available for a certain transformation, please use the *Overriding a WebHelp Responsive XSLT Stylesheet from an Ant Build File* method.

XSLT-Import Extension Points

The following extension points are available:

com.oxygenxml.webhelp.xsl.dita2webhelp

Extension point to override the XSLT stylesheet (`dita2webhelp.xsl`) that produces an HTML file for each DITA topic. The location of this topic is *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp.responsive\xsl\dita2webhelp\dita2webhelp.xsl`

com.oxygenxml.webhelp.xsl.createMainPage

Extension point to override the XSLT stylesheet (`createMainPage.xsl`) that produces the WebHelp Responsive main HTML page (`index.html`). The location of this file is *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createMainPage.xsl`

com.oxygenxml.webhelp.xsl.createSearchPage

Extension point to override the XSLT stylesheet (`createSearchPage.xsl`) that produces the WebHelp Responsive search HTML page (`search.html`). The location of this file is *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createSearchPage.xsl`

com.oxygenxml.webhelp.xsl.createIndexTermsPage

Extension point to override the XSLT stylesheet (`createIndextermsPage.xsl`) that produces the WebHelp Responsive index terms HTML page (`indexterms.html`). The location of this file is *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createIndextermsPage.xsl`

com.oxygenxml.webhelp.xsl.createTocXML

Extension point to override the XSLT stylesheet (`tocDita.xsl`) that produces the `toc.xml` file. This file contains information extracted from the *DITA map* and it is mainly used to construct the WebHelp Table of Contents and navigational links. The path to this stylesheet is: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\toc\tocDita.xsl`.

XSLT-Parameter Extension Points

If your customization stylesheet declares one or more XSLT parameters and you want to control their values from the transformation scenario, you can use one of the following XSLT parameter extension points:

com.oxygenxml.webhelp.xsl.dita2webhelp.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.xsl.dita2webhelp*** *extension point*.

com.oxygenxml.webhelp.xsl.createMainPage.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.xsl.createMainPage*** *extension point*.

com.oxygenxml.webhelp.xsl.createSearchPage.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.xsl.createSearchPage*** *extension point*.

com.oxygenxml.webhelp.xsl.createIndextermsPage.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.xsl.createIndexTermsPage*** *extension point*.

com.oxygenxml.webhelp.xsl.createTocXML.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.xsl.createTocXML*** *extension point*.

[DITA-OT] XSLT-Import Extension Points

[DITA-OT] XSLT-Parameter Extension Points

Example: Customizing Main Page Using XSLT-Import/Parameter Extension Points

This topic provides some common use-cases to demonstrate how to use the WebHelp Responsive XSLT-Import extension points to customize the main page. In this sample, the main page footer is modified by adding copyright information extracted from the DITA bookmap or by adding the output generation time. The first use-case uses an XSLT-Import extension point while the second uses an XSLT-Parameter extension point.

Note: This customization is available as a GitHub project at: *https://github.com/oxygenxml/com.oxygenxml.webhelp.responsive.custom.footer*.

Use Case 1: WebHelp XSLT-Import extension point to add copyright information extracted from DITA bookmap

Suppose you want to customize the WebHelp Responsive main page by adding information about the legal rights associated with the book in the footer (for example, copyright dates and owner). This information is specified in the bookmap:

```
<bookrights>
  <copyrfirst>
    <year>2002</year>
  </copyrfirst>
  <copyrlast>
    <year>2017</year>
  </copyrlast>
  <bookowner>
    <organization>SyncRO Soft SRL</organization>
  </bookowner>
</bookrights>
```

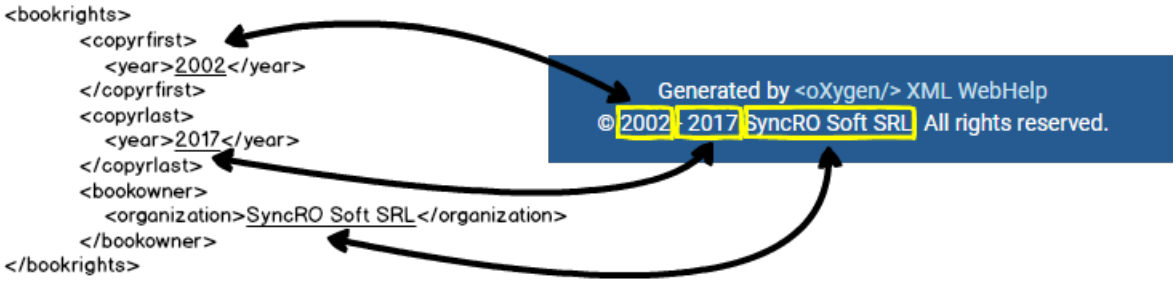

Figure 631: Example: Copyright information added in the WebHelp footer

The XSLT stylesheet that generates the main page is located in: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp.responsive\xsl\mainFiles\createMainPage.xsl`. This XSLT stylesheet declares the `copy_template` mode that processes the *main page template* to expand its components. The main page template declares a component for the footer section that looks like this:

```
<div class=" footer-container text-center ">
  <whc:include_html href="${webhelp.fragment.footer}"/>
</div>
```

In the following example, the extension stylesheet will add a template that matches this component. It applies the default processing and adds the copyright information at the end.

```
<xsl:template match="*:div[contains(@class, 'footer-container')]" mode="copy_template">
  <!-- Apply the default processing -->
  <xsl:next-match/>

  <!-- Add a div containing the copyright information -->
  <div class="copyright_info">
      <xsl:choose>
          <!-- Adds the start-end years if they are defined -->
          <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst) and
                          exists($toc/*:topicmeta/*:bookrights/*:copyrlast)">
              <span class="copyright_years">
                 &#xa9;<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
                      -<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrlast"/>
              </span>
          </xsl:when>

          <!-- Adds only the first year if last is not defined. -->
          <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst)">
              <span class="copyright_years">
```

```
                &#xa9;<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
            </span>
        </xsl:when>
    </xsl:choose>

    <xsl:if test="exists($toc/*:topicmeta/*:bookrights/*:bookowner/*:organization)">
        <span class="organization">
            <xsl:text> </xsl:text><xsl:value-of
                 select="$toc/*:topicmeta/*:bookrights/*:bookowner/*:organization"/>
            <xsl:text>. All rights reserved.</xsl:text>
        </span>
    </xsl:if>
  </div>
</xsl:template>
```

You can implement this functionality with a WebHelp extension plugin that uses the ***com.oxygenxml.webhelp.xsl.createMainPage*** *extension point*. This extension point allows you to specify a customization stylesheet that will override the template described above.

To add this functionality as a DITA-OT plugin, follow these steps:

1. In the *DITA-OT-DIR*`\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.webhelp.responsive.custom.footer`).
2. Create a **plugin.xml** file (in the folder you created in step 1) that specifies the extension point and your customization stylesheet. For example:

```
<plugin id="com.oxygenxml.webhelp.responsive.custom.footer">
  <feature extension="com.oxygenxml.webhelp.xsl.createMainPage"
           file="custom_mainpage.xsl"/>
</plugin>
```

3. Create your customization stylesheet (for example, **custom_mainpage.xsl**), and edit it to override the template that produces the footer section:

```
<xsl:template match="*:div[contains(@class, 'footer-container')]" mode="copy_template">
  <!-- Apply the default processing -->
  <xsl:next-match/>

  <!-- Add a div containing the copyright information -->
  <div class="copyright_info">
      <xsl:choose>
          <!-- Adds the start-end years if they are defined -->
          <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst) and
                       exists($toc/*:topicmeta/*:bookrights/*:copyrlast)">
              <span class="copyright_years">
                 &#xa9;<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
                       -<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrlast"/>
              </span>
          </xsl:when>

          <!-- Adds only the first year if last is not defined. -->
          <xsl:when test="exists($toc/*:topicmeta/*:bookrights/*:copyrfirst)">
              <span class="copyright_years">
                 &#xa9;<xsl:value-of select="$toc/*:topicmeta/*:bookrights/*:copyrfirst"/>
              </span>
          </xsl:when>
      </xsl:choose>

      <xsl:if test="exists($toc/*:topicmeta/*:bookrights/*:bookowner/*:organization)">
          <span class="organization">
              <xsl:text> </xsl:text><xsl:value-of
                   select="$toc/*:topicmeta/*:bookrights/*:bookowner/*:organization"/>
              <xsl:text>. All rights reserved.</xsl:text>
          </span>
      </xsl:if>
  </div>
</xsl:template>
```

4. Use the **Run DITA OT Integrator** transformation scenario found in the **DITA Map** section in the ***Configure Transformation Scenario(s)*** *dialog box*.
5. Run a **DITA Map WebHelp Responsive** transformation scenario to obtain the customized side TOC.

Use-Case 2: WebHelp XSLT-Parameter extension point to control if generation time is displayed in the output

Another possible customization for the main page is to add the generation time in its footer. You can use an XSLT-Parameter extension point to control if this customization is active or not. In this case, you can use the ***com.oxygenxml.webhelp.xsl.createMainPage.param*** *extension point*.

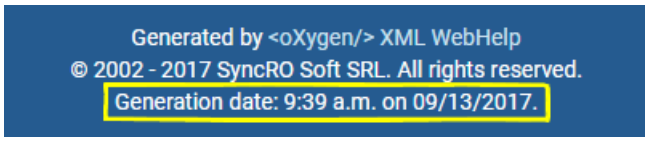

Figure 632: Generation time added in the WebHelp footer

To add this functionality, follow these steps:

1. Create a DITA-OT plugin structure by following the first 3 steps in the *procedure above*.
2. In the customization stylesheet that you created in step 3, declare the `webhelp.footer.add.generation.time` parameter and modify the template by adding the next XSLT code at the end.

```
<xsl:if test="$webhelp.footer.add.generation.time = 'yes'">
    <div class="generation_time">
        Generation date: <xsl:value-of select="format-dateTime(
              current-dateTime(), '[h1]:[m01] [P] on [M01]/[D01]/[Y0001].')"/>
    </div>
</xsl:if>
```

3. Edit the **plugin.xml** file to specify the **com.oxygenxml.webhelp.xsl.createMainPage.param** extension point and a custom parameter file by adding the following line:

```
<feature extension="com.oxygenxml.webhelp.xsl.createMainPage.param" file="params.xml"/>
```

4. Create a custom parameter file (for example, **params.xml**). It should look like this:

```
<dummy>
    <param name="webhelp.footer.add.generation.time"
        expression="${webhelp.footer.add.generation.time}"
        if="webhelp.footer.add.generation.time"/>
</dummy>
```

5. Use the **Run DITA OT Integrator** transformation scenario found in the **DITA Map** section in the ***Configure Transformation Scenario(s)*** *dialog box*.
6. Edit a **DITA Map WebHelp Responsive** transformation scenario and in the ***Parameters*** *tab*, specify the desired value (*yes* or *no*) for your custom parameter (`webhelp.footer.add.generation.time`).
7. Run the transformation scenario.

[DITA-OT] XSLT-Parameter Extension Points

Overriding a WebHelp XSLT Stylesheet from an Ant Build File

To create a WebHelp Responsive XSLT customization that is only available for a certain DITA OT transformation, the extension plugin should *declare a custom transtype*. The WebHelp Responsive XSLT stylesheets can be overridden from an ANT file provided by the DITA-OT extension plugin. From the Ant target associated with the plugin, you will specify a custom XSLT stylesheet that imports the original WebHelp Responsive stylesheet and add some customization templates.

The following procedure explains how to create a DITA-OT extension plugin that uses this extension method:

1. In the *DITA-OT-DIR*`\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.webhelp.responsive.custom`).
2. Create a **plugin.xml** file (in the folder you created in step 1) that specifies a new DITA-OT `transtype` and the build file associated with the plugin. For example:

```
<plugin id="com.oxygenxml.webhelp.responsive.custom">
    <feature extension="dita.conductor.target.relative" file="integrator.xml"/>
    <transtype name="webhelp-responsive-custom" extends="webhelp-responsive"
      desc="WebHelp Responsive Customization"/>
</plugin>
```

3. Create the **integrator.xml** file that will import the actual plugin Ant build file.

```
<project basedir="." name="Webhelp Responsive Customization">
    <import file="build.xml"/>
</project>
```

4. Create the **build.xml** file that overrides the value of properties associated with the *XSLT stylesheets used to produce HTML files*. The following Ant properties can be overridden to specify your customization stylesheets:

   `args.whr.topic.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce an HTML file for each topic*.

   `args.whr.create.main.page.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the HTML file associated with the main page*.

   `args.whr.create.search.page.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the HTML file associated with the search page*.

   `args.whr.create.indexterms.page.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the HTML file associated index the terms page*.

   `args.whr.createTocXML.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the toc.xml file*. The toc.xml file contains information extracted from DITA map and it is mainly used to create the WebHelp TOC.

   For example, to customize a WebHelp Responsive transformation type, the build file should look like:

```
<project basedir="." name="Webhelp Responsive Customization">
 <target name="dita2webhelp-responsive-custom">
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce an HTML file for each topic
   -->
   <property
     name="args.whr.topic.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.responsive.custom.dir}
                                                 /xsl/dita2webhelpCustom.xsl"/>
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce the main HTML file.
   -->
   <property
     name="args.whr.create.main.page.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.responsive.custom.dir}
                                            /xsl/createMainPageCustom.xsl"/>
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce the search HTML file.
   -->
   <property
     name="args.whr.create.search.page.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.responsive.custom.dir}
                                            /xsl/createSearchPageCustom.xsl"/>
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce the indexterms HTML file.
   -->
   <property
     name="args.whr.create.indexterms.page.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.responsive.custom.dir}
                                            /xsl/createIndextermsPageCustom.xsl"/>
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce the toc.xml file.
   -->
   <property
     name="args.whr.createTocXML.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.responsive.custom.dir}
                                            /xsl/createTocXMLCustom.xsl"/>
   <!--
     Now you need to delegate to the main target of the WevHelp Responsive transformation
   -->
   <antcall target="dita2webhelp-responsive"/>
 </target>
</project>
```

5. Create an **xsl** directory in the plugin customization directory (that you created in step 1) to store the customized XSLT stylesheets.
6. Now that the extension plugin is created, *install it in the DITA Open Toolkit*.

Referencing the WebHelp XSLT Stylesheets from Your Customizations

Note that your customization stylesheets should import the original stylesheets that they override. To reference the WebHelp Responsive stylesheets, you can use the **plugin:com.oxygenxml.webhelp.responsive** prefix. This prefix is rewritten by an XML catalog to the WebHelp Responsive root directory.

Customizing the `dita2webhelp.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **dita2webhelp.xsl** stylesheet should look like:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:math="http://www.w3.org/2005/xpath-functions/math"
   exclude-result-prefixes="xs math"
   version="2.0">
   <!--
     Import the original stylesheet used to produce an HTML file for each topic.
   -->
   <xsl:import href="plugin:com.oxygenxml.webhelp.responsive:xsl/
                                          dita2webhelp/dita2webhelp.xsl"/>
   <!--
     Please add your customization templates here.
   -->
</xsl:stylesheet>
```

Customizing the `createMainPage.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **createMainPage.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the main HTML file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.responsive:xsl/mainFiles/
                                            createMainPage.xsl"/>
    <!--
        Please add your customization templates here.
    -->

</xsl:stylesheet>
```

Customizing the `createSearchPage.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **createSearchPage.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the search HTML file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.responsive:xsl/mainFiles/
                                            createSearchPage.xsl"/>
    <!--
        Please add your customization templates here.
    -->

</xsl:stylesheet>
```

Customizing the `createIndextermsPage.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **createIndextermsPage.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the indexterms HTML file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.responsive:xsl/mainFiles/
                                            createIndextermsPage.xsl"/>
    <!--
        Please add your customization templates here.
    -->
```

```
</xsl:stylesheet>
```

Customizing the `tocDita.xsl` File

The XSLT stylesheet that customizes the WebHelp **tocDita.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the toc.xml file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.responsive:xsl/toc/tocDita.xsl"/>
    <!--
        Please add your customization templates here.
    -->
</xsl:stylesheet>
```

Search Engine Optimization for DITA WebHelp

A **DITA Map WebHelp** transformation scenario can be configured to produce a `sitemap.xml` file that is used by search engines to aid crawling and indexing mechanisms. A *sitemap* lists all pages of a WebHelp system and allows webmasters to provide additional information about each page, such as the date it was last updated, change frequency, and importance of each page in relation to other pages in your WebHelp deployment.

The structure of the `sitemap.xml` file looks like this:

```
<urlset xmlns="http://www.sitemaps.org/schemas/sitemap/0.9">
  <url>
    <loc>http://www.example.com/topics/introduction.html</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  <url>
    <loc>http://www.example.com/topics/care.html#care</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  .  .  .
</urlset>
```

Each page has a `<url>` element structure containing additional information, such as:

- `loc` - the URL of the page. This URL must begin with the protocol (such as `http`), if required by your web server. It is constructed from the value of the `webhelp.sitemap.base.url` parameter from the transformation scenario and the relative path to the page (collected from the `href` attribute of a `topicref` element in the *DITA map*).

  Note: The value must have fewer than 2,048 characters.
- `lastmod` (optional) - the date when the page was last modified. The date format is `YYYY-MM-DD`.
- `changefreq` (optional) - indicates how frequently the page is likely to change. This value provides general information to assist search engines, but may not correlate exactly to how often they crawl the page. Valid values are: `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, and `never`. The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.change.frequency` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.

  Note: The value `always` should be used to describe documents that change each time they are accessed. The value `never` should be used to describe archived URLs.
- `priority` (optional) - the priority of this page relative to other pages on your site. Valid values range from 0.0 to 1.0. This value does not affect how your pages are compared to pages on other sites. It only lets the search engines know which pages you deem most important for the crawlers. The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.priority` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.

Creating and Editing the `sitemap.xml` File

Follow these steps to produce a `sitemap.xml` file for your WebHelp system, which can then be edited to fine-tune search engine optimization:

1. **Edit** the transformation scenario you currently use for obtaining your WebHelp output. This opens the **Edit DITA Scenario** dialog box.
2. Open the **Parameters** tab and set a value for the following parameters:
   - `webhelp.sitemap.base.url` - the URL of the location where your WebHelp system is deployed

     Note: This parameter is required for Oxygen XML Editor to generate the `sitemap.xml` file.
   - `webhelp.sitemap.change.frequency` - how frequently the WebHelp pages are likely to change (accepted values are: `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, and `never`)
   - `webhelp.sitemap.priority` - the priority of each page (value ranging from 0.0 to 1.0)
3. Run the transformation scenario.
4. Look for the `sitemap.xml` file in the transformation's output folder. Edit the file to fine-tune the parameters of each page, according to your needs.

Support for Right-to-Left (RTL) Oriented Languages for DITA WebHelp

To activate support for RTL (right-to-left) languages in WebHelp output, edit the *DITA map* and set the `xml:lang` attribute on its root element (`map`). The corresponding attribute value can be set for following RTL languages:

- `ar-eg` - Arabic
- `he-il` - Hebrew
- `ur-pk` - Urdu

WebHelp Responsive Runtime Additional Parameters

A deployed WebHelp Responsive system can accept the following GET parameters:

- `contextId` - The WebHelp JavaScript engine will look for this value in the `context-help-map.xml` mapping file and load the corresponding help page. For more information, see the *Context-Sensitive WebHelp System* topic.

  Note: You can use an *anchor* in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.
- `appname` - You can use this parameter in conjunction with `contextId` to search for this value in the corresponding *appname attribute value* in the mapping file.

  ```
  http://localhost/webhelp/index.html?contextId=topicID&appname=myApplication
  ```
- `searchQuery` - You can use this parameter to perform a search operation when WebHelp is loaded. For example, if you want to open WebHelp showing all search results for *growing flowers*, the URL should look like this: `http://localhost/webhelp/index.html?searchQuery=growing%20flowers`.

Related Information:

Context-Sensitive WebHelp Responsive System on page 1201

Context-Sensitive WebHelp Responsive System

Context-sensitive help systems assist users by providing specific informational topics for certain components of a user interface, such as a button or window. This mechanism works based on mappings between a unique ID defined in the topic and a corresponding HTML page.

Generating Context-Sensitive Help

When WebHelp Responsive output is generated by Oxygen XML Editor, the transformation process produces an XML mapping file called `context-help-map.xml` and copies it in the output folder of the transformation. This XML file maps an ID to a corresponding HTML page through an `appContext` element, as in the following example:

```
<map productID="oxy-webhelp" productVersion="1.1">
  <appContext helpID="myapp-functionid1" path="tasks/app-help1.html"/>
  <appContext helpID="myapp-functionid2" path="tasks/app-help1.html"/>
    . . .
```

```
</map>
```

The possible attributes are as follows:

helpID

A Unique ID provided by a topic from two possible sources (`resourceid` element or `id` attribute):

resourceid

The `resourceid` element is mapped into the `appContext` element and can be specified in either the `topicref` within a *DITA map* or in a `prolog` within a DITA topic. The `resourceid` element accepts the following attributes:

- **appname** - A name for the external application that references the topic. If this attribute is not specified, its value is considered to be empty (" ").
- **appid** - An ID used by an application to identify the topic.
- **id** - Specifies a value that is used by a specific application to identify the topic, but this attribute is ignored if an **appid** attribute is used.

Note: Multiple `appid` values can be associated with a single `appname` value (and multiple `appname` values can be associated with a single `appid` value), but the values for both attributes work in combination to specify a specific ID for a specific application, and therefore each combination of values for the `appid` and `appname` attributes should be unique within the context of a single *root map*. For example, suppose that you need two different functions of an application to both open the same WebHelp page.

Example: `resourceid` Specified in a DITA Map

The `resourceid` element can be specified in a `topicmeta` element within a `topicref`.

```
<map title="App Help">
  <topicref href="app-help1.dita" type="task">
     <topicmeta>
       <resourceid appname="myapp" appid="functionid1"/>
       <resourceid appname="myapp" appid="functionid2"/>
     </topicmeta>
  </topicref>
</map>
```

Example: `resourceid` Specified in a DITA Topic

The `resourceid` element can be specified in a `prolog` element within a DITA topic.

```
<task id="app-help1">
  <title>My App Help</title>
  <prolog>
    <resourceid appname="myapp" appid="functionid1"/>
    <resourceid appname="myapp" appid="functionid2"/>
  </prolog>
...
</task>
```

For more information about the `resourceid` element, see *DITA Specifications: <resourceid>*.

id

If a `resourceid` element is not declared in the *DITA map* or DITA topic (as described above), the `id` attribute that is set on the topic root element is mapped into the `appContext` element.

Important: You should ensure that these defined IDs are unique in the context of the entire DITA project. If the IDs are not unique, the transformation scenario will display warning messages in the transformation console output and the help system will not work properly.

path

The path to a corresponding WebHelp page. This path is relative to the location of the `context-help-map.xml` mapping file.

productID (Applicable only if you are using the WebHelp Responsive with Feedback transformation scenario)

The ID of the product for your documentation project.

`productVersion` (Applicable only if you are using the WebHelp Responsive with Feedback transformation scenario)

The version of the product for your documentation project.

There are two ways of implementing context-sensitive help in your system:

- The XML mapping file can be loaded by a PHP script on the server side. The script receives the `contextId` value and will look it up in the XML file.
- Invoke the `index.html` WebHelp system file and pass the `contextId` parameter with a specific value. The WebHelp system will automatically open the help page associated with the value of the `contextId` parameter.

```
index.html?contextId=myDITATopic
```

Note: The `contextId` parameter is not case sensitive.

Context-Sensitive Queries

You can use the URL field in your browser to search for topics in a context-sensitive WebHelp system with the assistance of the following parameters:

- `contextId` - The WebHelp JavaScript engine will look for this value in the `context-help-map.xml` mapping file and load the corresponding help page. For more information, see the *Context-Sensitive WebHelp System* topic.

  Note: You can use an *anchor* in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.
- `appname` - You can use this parameter in conjunction with `contextId` to search for this value in the corresponding *appname attribute value* in the mapping file.

```
http://localhost/webhelp/index.html?contextId=topicID&appname=myApplication
```

WebHelp Responsive Runtime Additional Parameters on page 1201

Publishing WebHelp Responsive Output on a SharePoint Site

Since WebHelp output must be published locally, on the same machine where the WebHelp process is running, to publish your files directly to a SharePoint library you need to map a network drive to connect to SharePoint and change your file extensions to `.aspx`, as described in the steps below.

To publish WebHelp Responsive output on a SharePoint site, follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: *https://support.microsoft.com/en-us/kb/2616712*.
2. To allow browsers to open your published files (rather than downloading them), you need to change the file extensions from `.html` to `.aspx`. Fortunately, this can be done in the transformation scenario.
   a. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   b. Set the `args.outext` parameter to `.aspx`.
   c. Run the transformation scenario.

WebHelp Classic System

WebHelp is a form of online help that consists of a series of web pages (XHTML format). Its advantages include platform independence, ability to update content continuously, and it can be viewed using a regular web browser. The Oxygen XML Editor WebHelp system includes several variants to suit your specific needs. The **WebHelp Classic** variant is designed for desktop systems when feedback from users is not necessary and it is available for DocBook and DITA document types.

Layout of the WebHelp Classic System Interface

The layout of the **WebHelp Classic** system is comprised of the following components:

Left Pane or Frame

This section on the left side of the help system includes the following tabs:

Content

A typical table of contents style presentation of your content. You can use the **Expand all/Collapse all** buttons to expand or collapse all the topics presented in the Table of Contents.

Note: You can enhance the appearance of items in the *Table of Contents*. See the *Customizing WebHelp Classic Systems chapter* for more details.

Index

Presents the index terms for your content. If your content does not contain any `indexterm` elements, this tab is not generated.

Search Results

This tab is generated when the **Search** field is used. It presents the search results in the form of links to topics where the search terms are found, along with a rating scheme for each result. For more details, see the *Search Feature section*.

Upper Pane or Frame

The upper section of the help system includes the following features:

Search Field

Use this feature to perform searches in your content. When you enter search terms in this field, the results are displayed in the **Search Results** tab in the left section of the help system, along with a rating scheme for each result. For more details, see the *Search Feature section*.

Frames Option

Click on this option to display the output rendered in HTML frames.

Print Option

Opens a dialog box with various printing options and a print preview.

Navigation Links

You can navigate through the content of your output using the navigation links or arrows in the upper-right part of the page. These arrows allow you to move to the **Parent topic**, **Previous topic**, or **Next topic**. Links to the parent topics of the currently opened topic are also presented at the top of the page. For DITA output, these navigation links are controlled by the *`collection-type` attribute*.

Tip: To hide the **Parent**, **Next**, and **Previous** links, you can edit the transformation scenario and set the value of the `args.hide.parent.link` parameter to `yes`.

Main Pane or Frame

The content of the help pages are rendered and displayed in this main section.

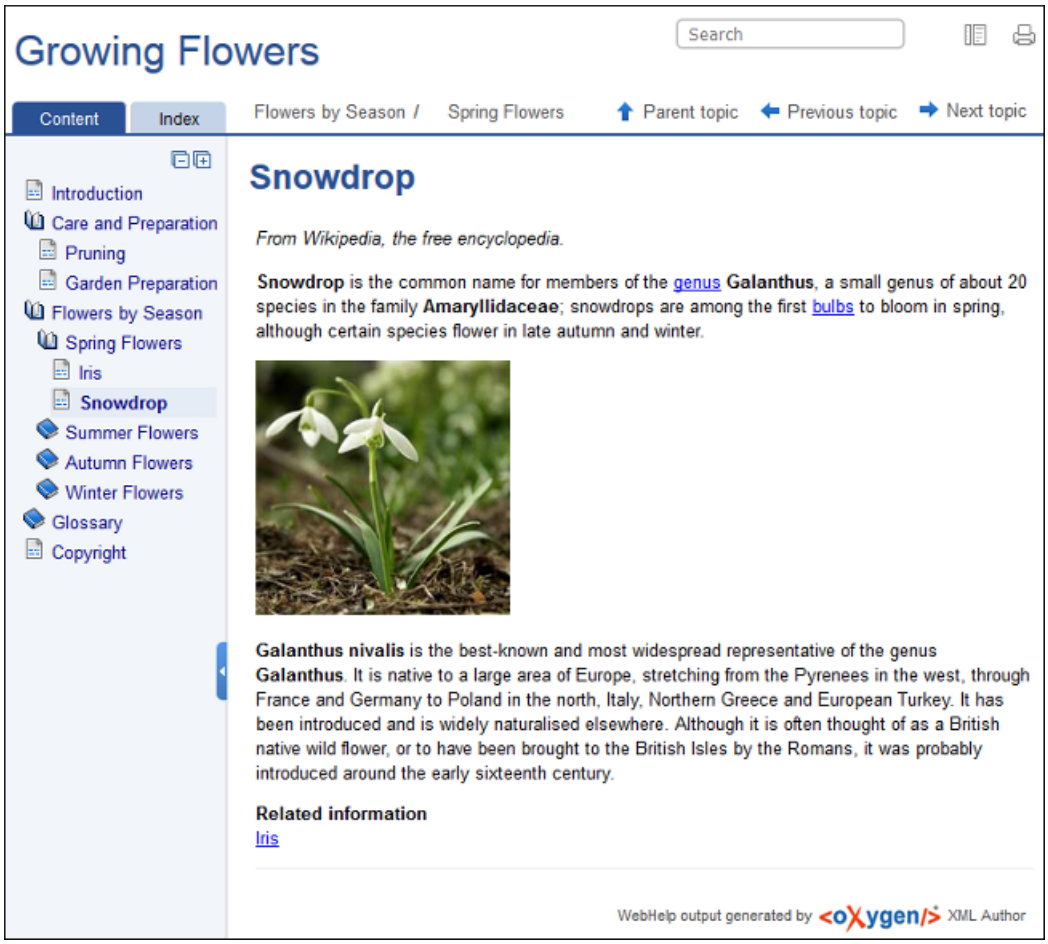

Figure 633: WebHelp Classic Output

WebHelp Classic Search Engine
Search Rules

Rules that are applied during a search include:

- You can use quotes to perform an exact search for multiple word phrases (for example, *"grow flowers"* will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a *phrase search*.
- *Boolean Search* is supported using the following operators: *and*, *or*, *not*. When there are two adjacent search terms without an operator, *or* is used as the default search operator (for example, *grow flowers* is the same as *grow or flowers*).
- The space character separates keywords (an expression such as *grow flowers* counts as two separate keywords: *grow* and *flowers*).
- `indexterm` and `keywords` DITA elements are an effective way to increase the ranking of a page (for example, content inside a *keywords* element weighs more than an *H1* HTML element).
- Words composed by merging two or more words with colon (":"), minus ("-"), underline ("_"), or dot (".") characters count as a single word.
- Your search terms should contain two or more characters (note that stop words will be ignored). This rule does not apply to CJK (Chinese, Japanese, Korean) languages.

5-Star Rating Mechanism and Sorting

The **Search** feature is also enhanced with a rating mechanism that computes scores for every result that matches the search criteria. These scores are then translated into a 5-star rating scheme and the stars are displayed to the right of each result. The search results are sorted depending on the following:

- Search entries that satisfy the phrase search criterion are presented first.
- The number of keywords found in a single page (the higher the number, the better).

- The context (for example, a word found in a title scores better than a word found in unformatted text). The search ranking order, sorted by relevance is as follows:
  - The search term is included in a meta keyword
  - The search term is in the title of the page
  - The search term is in bold text in a paragraph
  - The search term is in normal text in a paragraph

Excluded Terms

To improve performance, the **Search** feature excludes certain *stop words*. For example, the English version of such *stop words* include: *a, an, and, are, as, at, be, but, by, for, if, in, into, is, it, no, not, of, on, or, such, that, the, their, then, there, these, they, this, to, was, will, with*.

WebHelp Classic Search Results Tab

When you enter search terms in the **Search** field at the top of the help system, the results are displayed in the **Search Results** tab in the left section. When you click on a result in the **Search Results** tab, that result is displayed in the main pane with the search terms highlighted. If you press **Enter** with the **Search** field empty, the highlights are removed.

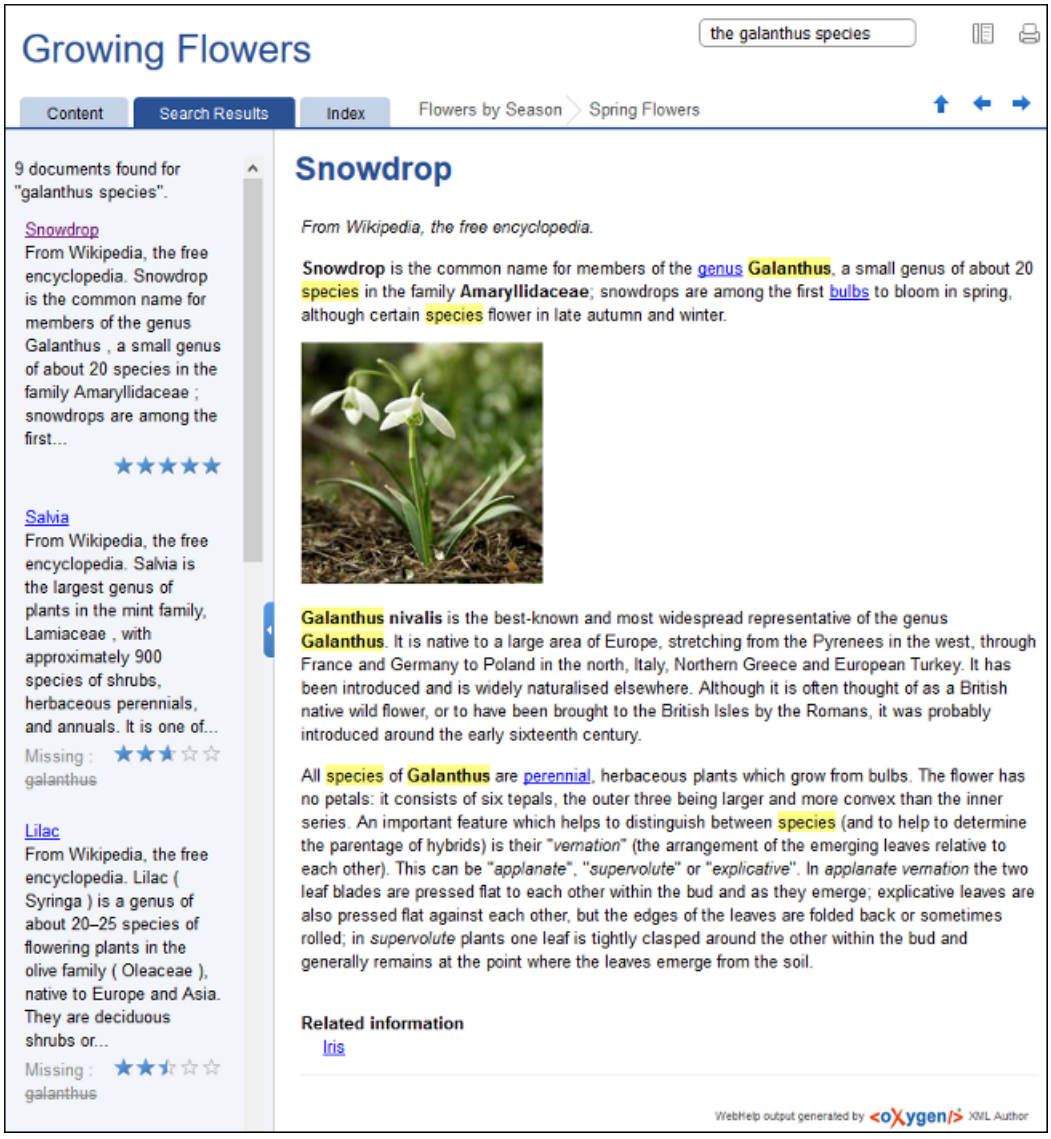

Figure 634: WebHelp Classic Search Results Tab

Missing Terms

If you enter multiple search terms (other than *stop words*), for any result that the search engine found at least one term but not one or more of the other terms, the **Missing** terms will be listed below each result.

Tag Element Scoring Values

HTML tag elements are also assigned a scoring value and these values are evaluated for the search results. For information about editing these values, see *Editing Scoring Values of Tag Elements in Search Results* on page 1186.

Browser Compatibility

This output format is compatible with the most recent versions of the following common browsers:

- Edge
- Internet Explorer (IE 10 or newer)
- Chrome
- Firefox
- Safari
- Opera

Important: Due to some security restrictions in certain browsers (Google Chrome and Internet Explorer), WebHelp Classic pages loaded from the local system (through URLs of the `file:///...` format) may not work properly. We recommend that you load WebHelp Classic pages in Google Chrome or Internet Explorer only from a web server (with a URL such as `http://your.server.com/webhelp/index.html` or `http://localhost/web_pages/index.html`).

Warning: Due to some restrictions in web browsers in regards to JavaScript code, the *frameless* version (`index.html` start page) of the WebHelp Classic system should only be loaded from a web server (with a URL such as `http://your.server.com/webhelp/index.html` or `http://localhost/web_pages/index.html`). When loading WebHelp Classic pages from the local file system, the *frameset* version (`index_frames.html` start page) of the WebHelp Classic system should be used instead (`file:///...`).

WebHelp Classic with Feedback System

WebHelp is a form of online help that consists of a series of web pages (XHTML format). Its advantages include platform independence, ability to update content continuously, and a feedback mechanism that allows your authors and audience to interact with one another through comments. The Oxygen XML Editor WebHelp system includes several variants to suit your specific needs. The **WebHelp Classic with Feedback** variant is designed for desktop systems, includes a feedback system that allows your users to make comments and allows you to manage and reply to them, and it is available for DocBook and DITA document types.

Layout

The layout of the **WebHelp Classic with Feedback** system is comprised of the following components:

Left Pane or Frame

This section on the left side of the help system includes the following tabs:

Content

A typical table of contents style presentation of your content. You can use the  **Expand all/**  **Collapse all** buttons to expand or collapse all the topics presented in the Table of Contents.

Note: You can enhance the appearance of items in the *Table of Contents*. See the *Customizing WebHelp Classic Systems chapter* for more details.

Index

Presents the index terms for your content. If your content does not contain any `indexterm` elements, this tab is not generated.

Search Results

This tab is generated when the **Search** field is used. It presents the search results in the form of links to topics where the search terms are found, along with a rating scheme for each result. For more details, see the *Search Feature section*.

Upper Pane or Frame

The upper section of the help system includes the following features:

Search Field

Use this feature to perform searches in your content. When you enter search terms in this field, the results are displayed in the **Search Results** tab in the left section of the help system, along with a rating scheme for each result. For more details, see the *Search Feature section*.

 **Frames Option**

Click on this option to display the output rendered in HTML frames.

 **Print Option**

Opens a dialog box with various printing options and a print preview.

Navigation Links

You can navigate through the content of your output using the navigation links or arrows in the upper-right part of the page. These arrows allow you to move to the **Parent topic**, **Previous topic**, or **Next topic**. Links to the parent topics of the currently opened topic are also presented at the top of the page. For DITA output, these navigation links are controlled by the *`collection-type` attribute*.

Tip: To hide the **Parent**, **Next**, and **Previous** links, you can edit the transformation scenario and set the value of the `args.hide.parent.link` parameter to `yes`.

Main Pane or Frame

The content of the help pages are rendered and displayed in this main section.

Feedback Section

The **WebHelp Classic with Feedback** system contains a **Comments** bar at the bottom of the main pane. This section is where you can interact with users through a comment system.

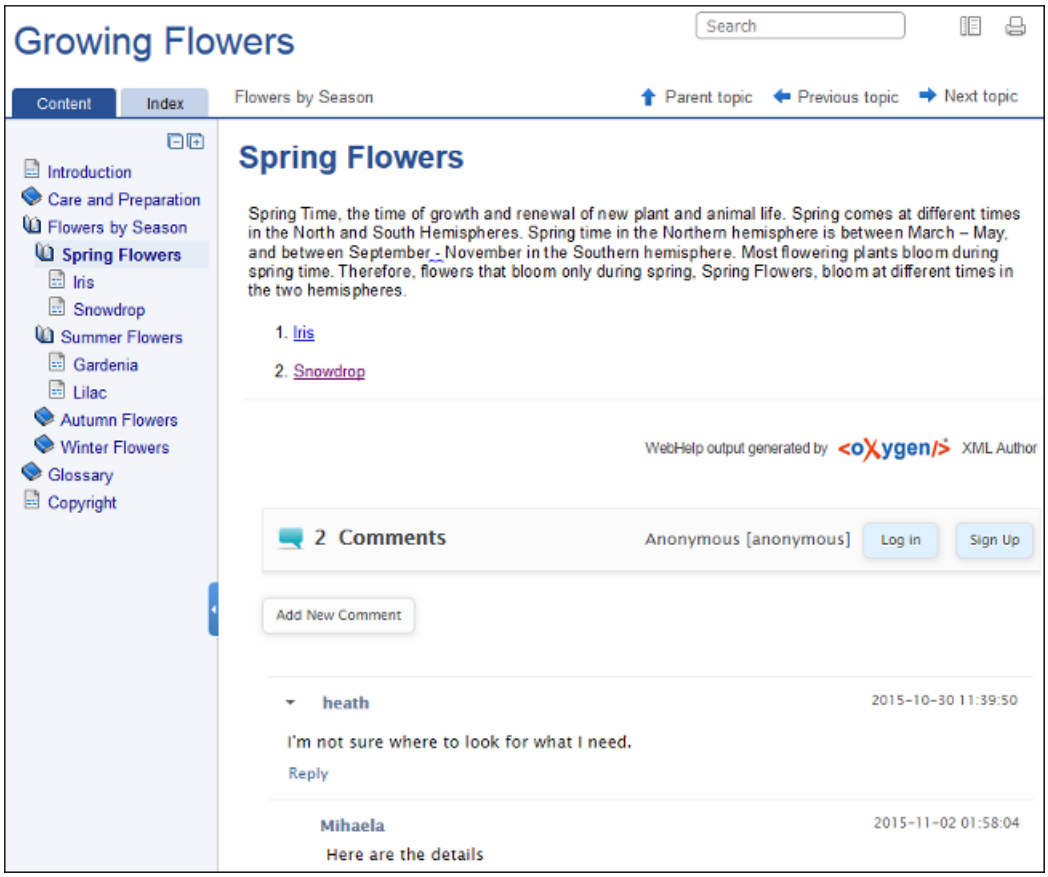

Figure 635: WebHelp Classic with Feedback System

Managing Comments

To add a new comment, click the **Add New Comment** button, or click **Reply** to add a comment to an existing thread. You can click on the **Log in** button on the right side of this bar to be authenticated as a user and your user name will be included in any comments that you add. If you do not have a user name, you can click on the **Sign Up** button to create a new user.

After you log in, your name and user name are displayed in the **Comments** bar, along with the **Log off** and **Edit** buttons. Click the **Edit** button to open the **User Profile** dialog box where you can customize the following options:

- **Your Name** - You can use this field to edit the initial name that you used to create your user profile.
- **Your email address** - You can use this field to edit the initial email address that you used to create your profile.
- You can choose to receive an email in the following situations:
  - When a comment is left on a page that you commented on.
  - When a comment is left on any topic in the WebHelp Classic system.
  - When a reply is left to one of my comments.
- **New Password** - Allows you to enter a new password for your user account.

  Note: The **Current Password** field from the top of the **User Profile** is mandatory if you want to save the changes you make.

If you are an administrator, you can manage user information and comments. For more information, see *Managing Users and Comments in a Feedback-Enabled WebHelp System* on page 1162.

WebHelp Classic Search Engine
Search Rules

Rules that are applied during a search include:

- You can use quotes to perform an exact search for multiple word phrases (for example, *"grow flowers"* will only return results if both words are found consecutively and exactly as they are typed in the search field). This type of search is known as a *phrase search*.
- *Boolean Search* is supported using the following operators: *and*, *or*, *not*. When there are two adjacent search terms without an operator, *or* is used as the default search operator (for example, *grow flowers* is the same as *grow or flowers*).
- The space character separates keywords (an expression such as *grow flowers* counts as two separate keywords: *grow* and *flowers*).
- `indexterm` and `keywords` DITA elements are an effective way to increase the ranking of a page (for example, content inside a *keywords* element weighs more than an *H1* HTML element).
- Words composed by merging two or more words with colon (":"), minus ("-"), underline ("_"), or dot (".") characters count as a single word.
- Your search terms should contain two or more characters (note that stop words will be ignored). This rule does not apply to CJK (Chinese, Japanese, Korean) languages.

5-Star Rating Mechanism and Sorting

The **Search** feature is also enhanced with a rating mechanism that computes scores for every result that matches the search criteria. These scores are then translated into a 5-star rating scheme and the stars are displayed to the right of each result. The search results are sorted depending on the following:

- Search entries that satisfy the phrase search criterion are presented first.
- The number of keywords found in a single page (the higher the number, the better).
- The context (for example, a word found in a title scores better than a word found in unformatted text). The search ranking order, sorted by relevance is as follows:
  - The search term is included in a meta keyword
  - The search term is in the title of the page
  - The search term is in bold text in a paragraph
  - The search term is in normal text in a paragraph

Excluded Terms

To improve performance, the **Search** feature excludes certain *stop words*. For example, the English version of such *stop words* include: *a, an, and, are, as, at, be, but, by, for, if, in, into, is, it, no, not, of, on, or, such, that, the, their, then, there, these, they, this, to, was, will, with*.

WebHelp Classic Search Results Tab

When you enter search terms in the **Search** field at the top of the help system, the results are displayed in the **Search Results** tab in the left section. When you click on a result in the **Search Results** tab, that result is displayed in the main pane with the search terms highlighted. If you press **Enter** with the **Search** field empty, the highlights are removed.

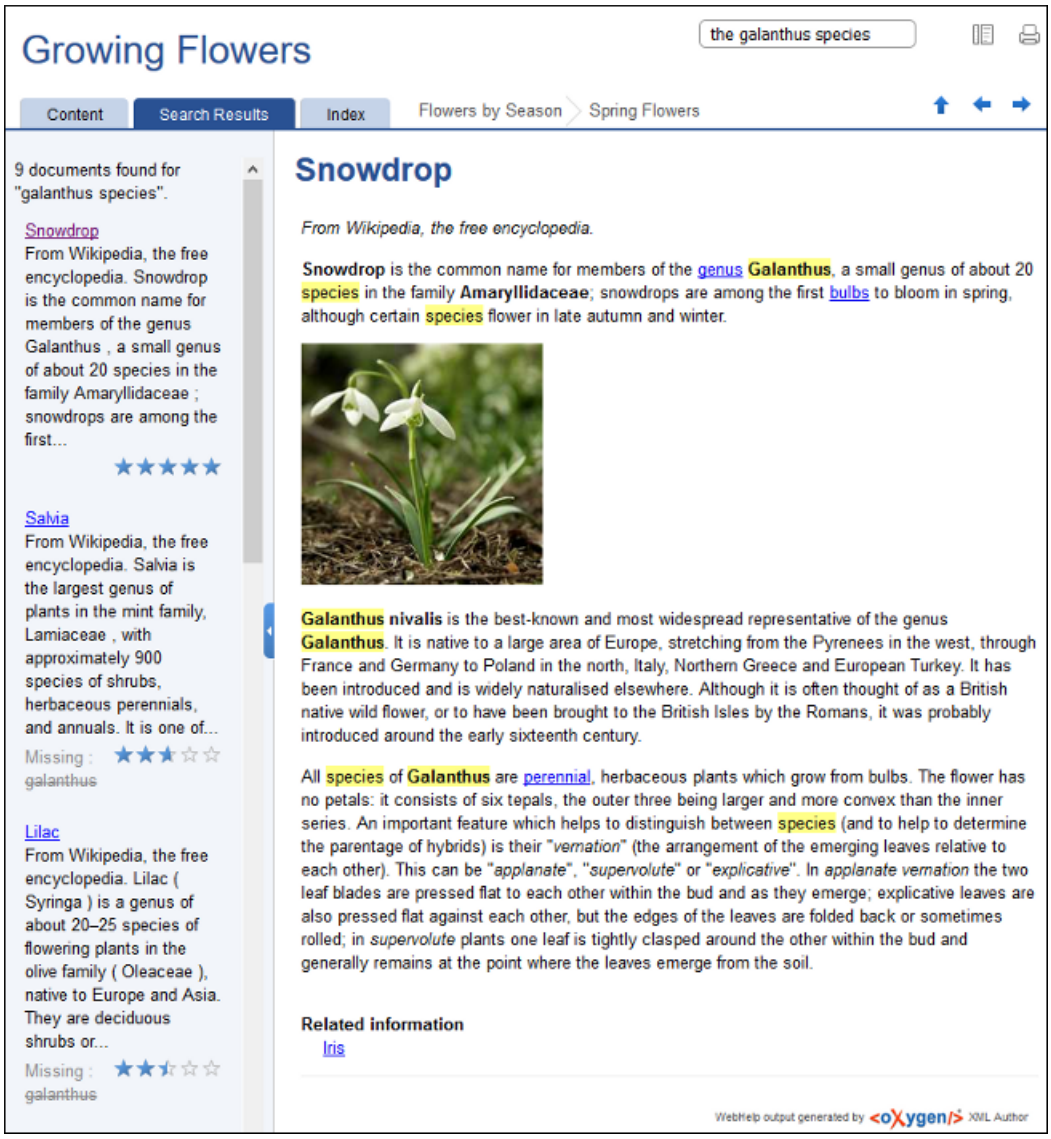

Figure 636: WebHelp Classic Search Results Tab

Missing Terms

If you enter multiple search terms (other than *stop words*), for any result that the search engine found at least one term but not one or more of the other terms, the **Missing** terms will be listed below each result.

Tag Element Scoring Values

HTML tag elements are also assigned a scoring value and these values are evaluated for the search results. For information about editing these values, see *Editing Scoring Values of Tag Elements in Search Results* on page 1186.

Browser Compatibility

This output format is compatible with the most recent versions of the following common browsers:

- Edge
- Internet Explorer (IE 10 or newer)
- Chrome
- Firefox
- Safari
- Opera

Important: Due to some security restrictions in certain browsers (Google Chrome and Internet Explorer), WebHelp Classic pages loaded from the local system (through URLs of the `file:///...` format) may not work properly. We recommend that you load WebHelp Classic pages in Google Chrome or Internet Explorer only from a web server (with a URL such as `http://your.server.com/webhelp/index.html` or `http://localhost/web_pages/index.html`).

Deploying a Feedback-Enabled WebHelp System

System Requirements

The feedback-enabled WebHelp system of Oxygen XML Editor requires a standard server deployment. You can request this from your server admin and it needs the following system components:

- A Web server (such as *Apache Web Server*)
- A *MySQL* or *MariaDB* database server
- A database admin tool (such as *phpMyAdmin*)
- PHP Version 5.1.6 or later

Oxygen XML WebHelp system supports most of the recent versions of the following browsers: Chrome, Firefox, Edge, Internet Explorer, Safari, Opera.

Create WebHelp with Feedback Database

The **WebHelp with Feedback** system needs a database to store user details and the actual feedback, and a user added to it with all privileges. After this is created, you should have the following information:

- Database name
- Username
- Password

Exactly how you create the database and user depends on your web host and your particular needs.

Example:

The following procedure uses *phpMyAdmin* to create a MySQL database for the feedback system and a MySQL user with privileges for that database. The feedback system uses these credentials to connect to the database.

Using *phpMyAdmin* to create a database:

1. Access the *phpMyAdmin* instance running on your server.
2. Click *Databases* (in the right frame) and then create a *database*. You can give it any name you want (for example *comments*).
3. Create a user with connection privileges for this database.
4. Under *localhost*, in the right frame, click *Privileges* and then at the bottom of the page click the **reload the privileges** link.

Deploying the WebHelp with Feedback Output

If you have a web server configured with PHP and MySQL, you can deploy the **WebHelp with Feedback** output by following these steps:

1. Connect to your server using an FTP client.
2. Locate the home directory (from now on, referred to as *DOCUMENT_ROOT*) of your server.
3. Copy the transformation output folder into the `DOCUMENT_ROOT` folder.
4. Rename it to something relevant (for example, `myProductWebHelp`).
5. Open the output folder (for example, `http://[YOUR_SERVER]/myProductWebHelp/`). You are redirected to the installation wizard. Proceed with the installation as follows:
   a. Verify that the prerequisites are met.
   b. Press **Start Installation**.
   c. Configure the **Deployment Settings** section. Default values are provided, but you should adjust them as needed.

Tip: You can change some of the options later. The installation creates a `config.php` file in `[OXYGEN_WEBHELP_INSTALL_DIR]/feedback/resources/php/config/config.php` where all your configuration options are stored.

d. Configure the **MySql Database Connection Settings** section. Use the information (database name, username, password) from the *Create WebHelp with Feedback Database section* to fill-in the appropriate text boxes.

Warning: Selecting the **Create new database structure** option will overwrite any existing data in the selected database, if it already exists. Therefore, it is useful the first time you install the **WebHelp with Feedback** system, but you do not want to select this option on subsequent deployments.

e. If you are using a domain (such as *OpenLDAP* or *Active Directory*) to manage users in your organization, select the **Enable LDAP Autehntication** option. This will allow you to configure the LDAP server, which will provide information and credentials for users who will access the WebHelp system. Also, this will allow you to choose which of the domain users will have administrator privileges.

f. If the **Create new database structure** option is selected, the **Create WebHelp Administrator Account** section becomes available. Here you can set the administrator account data. The administrator is able to moderate new posts and manage WebHelp users.

The same database can be used to store comments for multiple **WebHelp with Feedback** deployments. If a topic is available in multiple deployments and there are comments associated with it, you can choose to display the comments in all deployments that share the database. To do this, select the **Display comments from other products** option. In the **Display comments from** section, a list with the deployments sharing the same database is displayed. Select the deployments allowed to share common feedback.

Note: You can restrict the displayed comments of a product depending on its version. If you have two products that use the same database and you restrict one of them to display comments starting from a certain version, the comments of the other product are also displayed from the specified version onwards.

g. Press **Next Step**.

h. Remove the installation folder from your web server.

Important: When you publish subsequent iterations of your **WebHelp with Feedback** system, you will not upload the `/install` folder in the output, as you only need it uploaded the first time you create the installation. On subsequent uploads, you will just upload the other output files.

i. In your Web browser, go to your **WebHelp with Feedback** system main page.

Testing Your WebHelp with Feedback System

To test your system, create a user and post a comment. Check to see if the notification emails are delivered to your email inbox.

Note: To read debug messages generated by the system:

1. Enable *JavaScript* logging by doing one of the following:
   - Open the `log.js` file, locate the `var log= new Log(Level.NONE);` line, and change the logging level to: `Level.INFO`, `Level.DEBUG`, `Level.WARN`, or `Level.ERROR`.
   - Append `?log=true` to the WebHelp URL.
2. Inspect the PHP and Apache server log files.

Documentation Product ID and Version

When you run a **WebHelp with Feedback** transformation scenario, by default you are prompted for a documentation product ID and version number. This is needed when multiple WebHelp systems are deployed on the same server. Think of your WebHelp output as a *product*. If you have three different WebHelp outputs, you have three different *products* (each with their own unique documentation product ID). This identifier is included in a configuration file so that comments are tied to a particular output (product ID and version number).

Note: The **WebHelp with Feedback** installation includes a configuration option (**Display comments from other products**) that allows you to choose to have comments visible in other specified *products*.

Related Information:

Managing Users and Comments in a Feedback-Enabled WebHelp System on page 1162

Refreshing the Content of a Feedback-Enabled WebHelp System

It is common to update the content of an existing installation of a **WebHelp with Feedback** system on a regular basis. In this case, reinstalling the whole system is not a viable option since it might result in the loss of the comments associated with your topics. Also, reconfiguring the system every time you want to refresh it may be time consuming.

Fortunately, you can refresh just the content without losing the comments or the initial system configuration. To do so, follow these steps:

1. Execute the transformation scenario that produces the *WebHelp with Feedback* output directory.
2. Go to the output directory (specified in the **Output** tab of the transformation scenario), locate the `\feedback\resources\php\config\config.php` file, and delete it.
3. Locate the `\feedback\install` directory and delete it.
4. Copy the remaining structure of the output folder and paste it into your *WebHelp with Feedback* system installation directory, overwriting the existing content.

Managing Users and Comments in a Feedback-Enabled WebHelp System

When you installed the **WebHelp with Feedback** system the first time (assuming the ***Create new database structure** option* was selected), you should have been prompted to create an administrator account (or a user named *administrator* was created by default). As an administrator, you have access to manage comments posted in your feedback-enabled WebHelp system. You can also manage the user information (such as role, status, or notification options).

To manage comments and user information, follow these steps:

1. At the bottom of each specific topic there is a **Comments** navigation bar and on the right side there is a **Log in** button. Click this button and log in with your administrator credentials. This gives you access to an **Admin Panel** button.
2. Click the **Admin Panel** button to display an administration page.

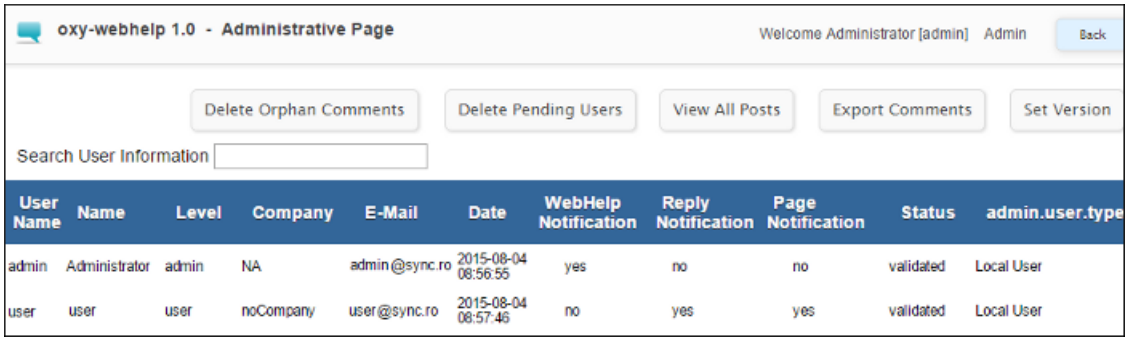

Figure 637: Administrative Page

3. Use this page to manage the following options:

Delete Orphaned Comments

Allows you to delete comments that are no longer associated with a topic in your WebHelp system.

Delete Pending Users

Allows you to delete user accounts that you do not wish to activate.

View All Posts

Allows you to view all the comments that are associated with topics in your WebHelp system.

Export Comments

Allows you to export all posts associated with topics in your WebHelp system into an XML file.

Set Version

Use this action to display comments starting with a particular version.

Manage User Information

To edit the details for a user, click on the corresponding row. This opens a window that allows you to customize the following information associated with the user:

Name

The full name of the user.

Level

Use this field to modify the privilege level (role) for the selected user. You can choose from the following:

- **User** - Regular user, able to post comments and receive e-mail notifications.
- **Moderator** - In addition to the regular **User** rights, this type of user has access to the **Admin Panel** where a moderator can view, delete, export comments, and set the version of the feedback-enabled WebHelp system.
- **Admin** - Full administrative privileges. Can manage WebHelp-specific settings, users, and their comments.

Company

The name of the organization associated with the user.

E-Mail

The contact email address for the user. This is also the address where the WebHelp system sends notifications.

WebHelp Notification

When selected, the user receives notifications when comments are posted anywhere in your feedback-enabled WebHelp system.

Reply Notification

When selected, the user receives notifications when comments are posted as a reply to one of their comments.

Page Notification

When selected, the user receives notifications when comments are posted on a topic where they previously posted a comment.

Date

The date the user registered is displayed.

Status

Use this drop-down list to change the status of the user. You can choose from the following:

- **Created** - The user is created but does not yet have any rights for the feedback-enabled WebHelp system.
- **Validated** - The user is able to use the feedback-enabled WebHelp system.
- **Suspended** - The user has no rights for the feedback-enabled WebHelp system.

Warning: The key used for identifying the page a comment is attached to is the relative file path to the output page. Since the output file and folder names mirror the source, any change to the file name (or its folder) in the source will affect the comments associated with that WebHelp page. If you change the file name or path, the comment history for that topic will become orphaned (a change to the topic ID does not affect the comment history).

Customizing WebHelp Classic Systems

To change the overall appearance of the WebHelp output, you can use the visual *WebHelp Skin Builder tool*, which does not require knowledge of CSS language. If you are familiar with CSS and coding, you can style your WebHelp output through your own custom stylesheets. You can also customize your output by modifying option and parameters in the transformation scenario.

This section includes topics that explain various ways to customize your WebHelp system output, such as how to improve the appearance of the Table of Contents, add logo images in the title area, integrate with social media, add custom headers and footers, and much more.

Copying Additional Resources to WebHelp Output Directory

To copy additional resources (such as JavaScript, CSS or other resources) to the output directory of a WebHelp system, follow these steps:

1. Place all your resources in the same directory.
2. Edit the WebHelp transformation scenario.
3. Go to the **Parameters** tab.
4. Edit the value for the webhelp.custom.resources parameter and set it to the absolute path of the directory in step 1.
5. Click **OK** to save the changes to the transformation scenario.
   All files from the new directory will be copied to the root of the WebHelp output directory.

Adding Custom HTML Content in WebHelp Classic Output

You can add custom HTML content in the WebHelp Classic output by inserting it in a well-formed XML file that will be referenced in the transformation scenario. This content may include references to additional JavaScript, CSS, and other types of resources, or such resources can be inserted inline within the HTML content that is inserted in the XML file.

To include custom HTML content in the WebHelp Classic output files, follow these steps:

1. Insert the HTML content in a well-formed XML file. There are several things to consider in regards to this XML file:
   a. **Well-Formedness** - If the file is not a *Well-formed XML document* (or fragments are not well-formed), the transformation will fail.

      A common use case is if you want to include several `script` or `link` elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in an `html` element. This element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `head`, `body`, `html/head`, or `html/body` elements.
   b. **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the predefined `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

      ```
      <html>
        <script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"/>
        <link rel="stylesheet" type="text/css"
              href="${oxygen-webhelp-output-dir}/css/test.css" />
      </html>
      ```

      To copy the referenced resources to the output directory, follow the procedure in: *Copying Additional Resources to WebHelp Output Directory* on page 1179.
   c. **Inline JavaScript or CSS Content** - If you want to include inline JavaScript or CSS content in the XML file, it is important to place this content inside an XML comment, as in the following examples:

      JavaScript:

      ```
      <script type="text/javascript">
        <!--
          /* Include JavaScript code here. */

          function myFunction() {
            return true;
          }
        -->
      </script>
      ```

      CSS:

      ```
      <style>
        <!--
          /* Include CSS style rules here. */

          *{
            color:red
          }
        -->
      </style>
      ```

2. Edit the WebHelp Classic transformation scenario.
3. Go to the **Parameters** tab.
4. Edit the value of the webhelp.head.script parameter and set it to the URL of the XML file created in step 1. Your additional content will be included at the end of the `head` element of your output document.

   Note: If you want to include the content in the `body` element, use the webhelp.body.script parameter instead.
5. Click **OK** to save the changes to the transformation scenario.

Copying Additional Resources to WebHelp Output Directory on page 1179

Adding a Button in Code Snippet Areas in DITA WebHelp Classic Output

This task will get you started with how to add an action (such as a button or link) in the code snippet areas that are displayed in WebHelp Classic output created from a *DITA map* transformation. You can then attach your code that does the actual processing for the action.

Follow these steps:

1. Open the *DITA-OT-DIR*`\plugins\org.dita.xhtml\xsl\xslhtml\dita2htmlImpl.xsl` file.
2. Locate the `<xsl:template match="*[contains(@class, ' topic/pre ')]" mode="pre-fmt">` template to check the default behavior of this template.
3. Open the *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\desktop\fixup.xsl` file.
4. Create a `<xsl:template match="*[contains(@class, ' topic/pre ')]" mode="pre-fmt">` template to override the default processing.
5. This new template will include your code for creating the button. It will have the action code that does the actual processing attached to it (this can be written in JavaScript, for example).

   Example of a *Select all* button:

```
<xsl:template match="*[contains(@class, ' topic/pre ')]" mode="pre-fmt">
    <button onclick="SelectText(element)">Select all</button>
    <script>
      function SelectText(element) {
        var text = document.getElementById(element);
        var range = document.body.createTextRange();
        range.moveToElementText(text);
        range.select();
      }
    </script>
  </xsl:template>
```

Adding a Favicon in WebHelp Systems

You can add a custom *favicon* to your WebHelp system by simply using a parameter in the transformation scenario to point to your *favicon* image. This is available for DITA and DocBook WebHelp systems using **WebHelp Responsive**, **WebHelp Responsive with Feedback**, **WebHelp Classic**, **WebHelp Classic with Feedback**, or **WebHelp Classic Mobile** transformation scenarios.

To add a *favicon*, follow these steps:

1. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
2. Locate the `webhelp.favicon` parameter and enter the file path that points to the image that will be use as the *favicon*.
3. Run the transformation scenario.

Adding a Logo Image in the Title Area

To add a logo in the title area of your WebHelp output, follow this procedure:

1. Edit a WebHelp transformation scenario, then open the **Parameters** tab.
2. Specify the path to your logo in the `webhelp.logo.image` parameter.
3. If you also want to add a link to your website when you click the logo image, set the URL in the `webhelp.logo.image.target.url` parameter.
4. Run the transformation scenario.

Adding Video and Audio Objects in DITA WebHelp Output

You can insert references to video and audio media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics and then publish them to WebHelp output. The media objects can be played directly in all HTML5-based outputs, including WebHelp systems.

To add media objects in the WebHelp output generated from DITA documents, follow the procedures below.

Adding Videos to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the video through one of the following methods:
   - Use the ***Insert Media Object*** *toolbar action*.
   - Drag (or copy) the video file from your system explorer or the ***Project*** *view* and drop (or paste) it into your document.
   - Manually add an `object` element, as in one of the following examples:

     ```
     <object outputclass="video" type="video/mp4" data="MyVideo.mp4"/>
     ```

     or, instead of the `data` attribute, you can specify the video using a parameter like this:

     ```
     <object outputclass="video">
       <param name="src" value="videos/MyVideo.mp4"/>
     </object>
     ```
2. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

   Result: The transformation converts the `object` element to an HTML5 `video` element.

   ```
   <video controls="controls"><source type="video/mp4" src="MyVideo.mp4"></source>
   </video>
   ```

Adding Audio Clips to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the audio clip through one of the following methods:
   - Use the ***Insert Media Object*** *toolbar action*.
   - Drag (or copy) the audio file from your system explorer or the ***Project*** *view* and drop (or paste) it into your document.
   - Manually add an `object` element, as in one of the following examples:

     ```
     <object outputclass="audio" type="audio/mpeg" data="MyClip.mp3"/>
     ```

     or, instead of the `data` attribute, you can specify the video using a parameter like this:

     ```
     <object outputclass="audio">
       <param name="src" value="audio/MyClip.mp3"/>
     </object>
     ```
2. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

   Result: The transformation converts the `object` element to an HTML5 `audio` element.

   ```
   <audio controls="controls"><source type="audio/mpeg" src="MyClip.mp3"></source>
   </audio>
   ```

Adding Embedded HTML Frames (such as YouTube videos) to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the embedded object by using the ***Insert Media Object*** *toolbar action* or by manually adding an `object` element, as in one of the following examples:

   ```
   <object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
   ```

   or, instead of the `data` attribute, you can specify the object using a parameter like this:

   ```
   <object outputclass="iframe">
     <param name="src" value="http://www.youtube.com/embed/m_vv2s5Trn4"/>
   ```

```
</object>
```

2. If you want the video to be allowed to play in full screen mode once the document is converted to XHTML output, also add an `allowfullscreen` parameter and set its value to **true**:

```
<object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
  <param name="allowfullscreen" value="true"/>
</object>
```

   Tip: If you copy the embed code from the source and paste it into the **Insert Media** dialog box (see the specific instructions: *here*), the `allowfullscreen` parameter will automatically be added and all you have to do is set the value to **true**.

3. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

   Result: The transformation converts the `object` element to an HTML5 `iframe` element.

```
<iframe controls="controls" src="https://www.youtube.com/embed/m_vv2s5Trn4">
</iframe>
```

For more information, see the following video demonstration:

Related Information:

Adding Video, Audio, and Embedded HTML Resources in DITA Topics on page 1830

Adding Videos in DocBook WebHelp Classic Output

You can insert references to videos in your DocBook topics and then publish them to **WebHelp Classic** output. The videos can be played directly in all HTML5-based outputs, including WebHelp systems.

To add videos in the **WebHelp Classic** output generated from DocBook documents, follow these steps:

1. Edit the DocBook document and reference the video using an `mediaobject` element, as in the following example:

```
<mediaobject>
  <videoobject>
    <videodata fileref="http://www.youtube.com/watch/v/VideoName"/>
  </videoobject>
</mediaobject>
```

2. Apply a *WebHelp* or *WebHelp with Feedback* transformation scenario to obtain the output.

Change Numbering Styles for Ordered Lists

Ordered lists (`ol`) are usually numbered in XHTML output using numerals. If you want to change the numbering to alphabetical, follow these steps:

1. Define a custom `outputclass` value and set it as an attribute of the ordered list, as in the following example:

```
<ol outputclass="number-alpha">
    <li>A</li>
    <li>B</li>
    <li>C</li>
</ol>
```

2. Add the following code snippet in a custom CSS file:

```
ol.number-alpha{
    list-style-type:lower-alpha;
}
```

3. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
4. Run the transformation scenario.

Changing the Icons in a WebHelp Classic Table of Contents

You can change the icons that appear in a WebHelp Classic table of contents by assigning new image files in a custom CSS file. By default, the icons for the WebHelp Classic table of contents are defined with the following CSS codes (the first example is the icon that appears for a collapsed menu and the second for an expanded menu):

```
.hasSubMenuClosed{
    background: url('../img/book_closed16.png') no-repeat;
    padding-left: 16px;
    cursor: pointer;
}
```

```
.hasSubMenuOpened{
    background: url('../img/book_opened16.png') no-repeat;
    padding-left: 16px;
    cursor: pointer;
}
```

To assign other icons, use the following procedure:

1. Create a custom CSS file that assigns your desired icons to the `.hasSubMenuClosed` and `.hasSubMenuOpened` properties.

   ```
   .hasSubMenuClosed{
       background: url('TOC-my-closed-button.png') no-repeat;
   }
   ```

   ```
   .hasSubMenuOpened{
       background: url('TOC-my-opened-button.png') no-repeat;
   }
   ```

2. It is recommended that you store the image files in the same directory as the default icons.
   a) For DITA transformations: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\img\`.
   b) For DocBook transformations: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\img\`.
3. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a) For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b) For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
4. Run the transformation scenario.

CSS Styling to Customize WebHelp Output

One way to customize WebHelp output is to use custom CSS styling. This method can be used to make small, simple styling changes or more advanced, precise changes. To implement the styling in your WebHelp output, you simply need to create the custom CSS file and reference it in your transformation scenario. This custom file will be the final CSS to be applied so its content will override the styles in the other pre-existing CSS files.

Using CSS Inspector to Identify Content for Custom CSS File

You can use your browser's CSS inspector to identify the pertinent code in the current CSS files and you can even make changes directly in the CSS inspector to test the results so that you know exactly what content to use in your custom CSS file.

In most popular browsers (such as Chrome, Firefox, and Edge), you can access the CSS inspector by using **F12** or by selecting **Inspect Element** (or simply **Inspect**) from the contextual menu. When using Safari on Mac OS X, you must first enable the Develop menu by going to the Advanced settings and selecting **Show Develop menu in menu bar**. Then you can select **Show Web Inspector** from the Develop menu or click **Command+Option+I**.

Example: How to Change the Background Color of the Footer Bar

As a practical example, the following procedure can be used to change the background color of the footer bar in the WebHelp output of the Oxygen XML Editor User Guide:

1. Use the browser's CSS inspector to identify the current CSS code that styles the footer bar. In this particular case, the pertinent code that would be identified is:

```
.wh_footer {
  font-size: 15px;
  line-height: 1.7em;
  background-color: #000;
}
```

2. If you want to test the color you want to apply as the background of this particular element, use the browser's CSS inspector to change the value of the `background-color` attribute. After you find a suitable color, copy that new code.
3. Create a custom CSS file and paste or enter the copied code. For example:

```
.wh_footer {
  background-color: #255890;
}
```

4. Save the custom CSS file at a location of your convenience.
5. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
6. Run the transformation scenario.

Result: Your custom CSS snippet will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

Customize the Appearance of Selected Items in the Table of Contents

The appearance of selected items in the table of contents of WebHelp Classic output can be enhanced.

For example, to highlight the background of the selected item, follow these steps:

1. Locate the `toc.css` file in the following directory:
   a. For DITA transformations: *`DITA-OT-DIR`*`\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\css`.
   b. For DocBook transformations: *`[OXYGEN_INSTALL_DIR]`*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\css`.
2. Edit that CSS file, find the `menuItemSelected` class, and change the value of the `background` property.

Note: You can also overwrite the same value from your own custom CSS and then specify the path to your CSS in the transformation scenario (see step 3 in the *Changing the Icons in a WebHelp Classic Table of Contents* topic.

Customizing WebHelp Output with a Custom CSS

By creating your own custom CSS stylesheet, you can customize the look and style of WebHelp output to fit your specific needs.

To use a custom CSS in WebHelp output, follow these steps:

1. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
2. Run the transformation scenario.

Disable Caching in WebHelp Classic Output

In cases where a set of WebHelp Classic pages need to be updated on a regular basis to deliver the latest version of the documentation, the WebHelp pages should always be requested from the server upon re-loading it in a Web browser on the client side, rather than re-using an outdated *cached* version in the browser.

To disable caching in WebHelp Classic output, follow this procedure:

1. Edit the following XSL file for DITA or DocBook WebHelp systems:
   - For DITA WebHelp systems, edit the following file: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\createMainFiles.xsl`.
   - For DocBook WebHelp system, edit the following file: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\xsl\createMainFiles.xsl`.
2. Locate the following template in the XSL file: `<xsl:template name-"create-toc-common-file">` and add the following code snippet:

```
<meta http-equiv="Pragma" content="no-cache" />
<meta http-equiv="Expires" content="-1" />
```

   Note: The code should look like this:

```
  <html>
    <head>
      <xsl:if test="$withFrames">
      <base target="contentwin"/>
      </xsl:if>
      <meta http-equiv="Content-Type" content="text/html; charset=utf-8"/>
           <!-- Disable caching of WebHelp pages in web browser. -->
      <meta http-equiv="Pragma" content="no-cache" />
      <meta http-equiv="Expires" content="-1" />
....
```

3. Save your changes to the file.
4. Re-run your WebHelp system transformation scenario.

Editing Scoring Values of Tag Elements in Search Results

The WebHelp **Search** feature is enhanced with a rating mechanism that computes scores for every page that matches the search criteria. HTML tag elements are assigned a scoring value and these values are evaluated for the search results. Oxygen XML Editor includes a properties file that defines the scoring values for tag elements and this file can be edited to customize the values according to your needs.

To edit the scoring values of HTML tag element for enhancing WebHelp search results, follow these steps:

1. Edit the scoring properties file for DITA or DocBook WebHelp systems. The properties file includes instructions and examples to help you with your customization.
   a) For DITA WebHelp systems, edit the following file: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\indexer\scoring.properties`.
   b) For DocBook WebHelp system, edit the following file: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\indexer\scoring.properties`.

   The values that can be edited in the `scoring.properties` file:

```
h1 = 10
h2 = 9
h3 = 8
h4 = 7
h5 = 6
h6 = 5
b = 5
strong = 5
em = 3
i=3
u=3
div.toc=-10
title=20
div.ignore=ignored
meta_keywords = 20
meta_indexterms = 20
meta_description = 25
shortdesc=25
```

2. Save your changes to the file.
3. Re-run your WebHelp system transformation scenario.

Exclude Certain DITA Topics from WebHelp Search Results

There are several ways to exclude certain DITA resources from your WebHelp system's search results. This is useful if you have topics in your *DITA map* structure that you do not want to be included in search results for your WebHelp system. The first method involves setting a parameter in the WebHelp transformation scenario and the second involves setting an attribute for each DITA topic reference that you want to exclude.

Transformation Parameter Method

To exclude DITA topics from WebHelp search results using a transformation parameter, follow these steps:

1. Create a simple text file that will contain your excluded file patterns. Each pattern must be on a new line. The patterns are considered to be relative to the output directory and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

   Example: Suppose that in your project, you want to exclude all files located in the `resources` directory and all files located in the `topics` directory that have a `.bak` file extension. You could create a simple text file (for example, named `exclude.properties`), and add the following lines:

   ```
   resources/*
   topics/*.bak
   ```

2. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
3. Set the `webhelp.search.custom.excludes.file` parameter to specify the path to the file that contains the excluded file patterns (for example, `exclude.properties` in step 1).
4. Run the transformation scenario.

Search Attribute Method

The WebHelp **Search** engine does not index DITA topics that have the `@search` attribute set to no.

To exclude DITA topics from WebHelp search results using this attribute, follow these steps:

1. Edit the *DITA map* and for any `topicref` that you want to exclude from search results, set the `search` attribute to no.

   For example:

   ```
   <topicref href="../topics/internal-topic1.dita" search="no"/>
   ```

2. Save your changes to the *DITA map*.
3. Run your WebHelp system transformation scenario.

Flag DITA Content in WebHelp Output

Flagging content in WebHelp output involves defining a set of images that will be used for marking content across your information set.

To flag DITA content, you need to create a filter file that defines properties that will be applied on elements to be flagged. Generally, flagging is supported for *block elements* (such as paragraphs), but not for phrase-level elements within a paragraph. This ensures that the images that will flag the content are easily scanned by the reader, instead of being buried in text.

Follow this procedure:

1. Create a DITA filter file in the directory where you want to add the file. Give the file a descriptive name, such as `audience-flag-build.ditaval`.
2. Define the property of the element you want to be flagged. For example, if you want to flag elements that have the `audience` attribute set to `programmer`, the content of the DITAVAL file should look like the following example:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <val>
     <prop att="audience" val="programmer" action="flag"
    img="D:\resource\delta.gif" alt="sample alt text"/>
   </val>
   ```

   Note that for an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.
3. Specify the DITAVAL file in the **Filters** tab of the transformation scenario.
4. Run the transformation scenario.

Integrating Social Media and Google Tools in WebHelp Output

Oxygen XML Editor includes support for integrating some of the most popular social media sites in WebHelp output.

How to Add a Facebook Like Button in WebHelp Classic Output

To add a Facebook™ *Like* widget to your WebHelp output, follow these steps:

1. Go to the *Facebook Developers* website.
2. Fill-in the displayed form, then click the **Get Code** button.
   A dialog box that contains code snippets is displayed.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`.

   Make sure you follow these rules:

   - The file must be well-formed.
   - The code for each `script` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

```
<div id="facebook">
    <div id="fb-root"/>
    <script>
        <!--
            (function(d, s, id) {
        var js, fjs = d.getElementsByTagName(s)[0];
        if (d.getElementById(id)) return;
        js = d.createElement(s); js.id = id;
        js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
        fjs.parentNode.insertBefore(js, fjs);
        }(document, 'script', 'facebook-jssdk'));
        -->
    </script>
    <div class="fb-like" data-layout="standard" data-action="like"
        data-show-faces="true" data-share="true"/>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `facebook-widget.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Add a Google+ Button in WebHelp Classic Output

To add a *Google+* widget to your WebHelp output, follow these steps:

1. Go to the *Google Developers* website.
2. Fill-in the displayed form.
   The preview area on the right side displays the code and a preview of the widget.
3. Copy the code snippet displayed in the preview area and paste it into a `div` element inside an XML file called `google-plus-button.xml`.

   Make sure that the content of the file is well-formed.

   The content of the XML file should look like this:

```
<div id="google-plus">
  <!-- Place this tag in your head or just before your close body tag. -->
  <script src="https://apis.google.com/js/platform.js" async defer></script>

  <!-- Place this tag where you want the +1 button to render. -->
```

```
  <div class="g-plusone" data-annotation="inline" data-width="300"></div>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `google-plus-button.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Add Tweet Button in WebHelp Classic Output

To add a Twitter™ *Tweet* widget to your WebHelp output, follow these steps:

1. Go to the *Tweet button generator* page.
2. Fill-in the displayed form.
   The **Preview and code** area displays the code.
3. Copy the code snippet displayed in the **Preview and code** area and paste it into a `div` element inside an XML file called `tweet-button.xml`.

   Make sure you follow these rules:

   - The file must be well-formed.
   - The code for each `script` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

```
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
    <!--
      !function (d, s, id) {
      var
      js, fjs = d.getElementsByTagName(s)[0], p = /^http:/.test(d.location)
 ? 'http': 'https';
      if (! d.getElementById(id)) {
      js = d.createElement(s);
      js.id = id;
      js.src = p + '://platform.twitter.com/widgets.js';
      fjs.parentNode.insertBefore(js, fjs);
      }
      }
      (document,
      'script', 'twitter-wjs');
     -->
  </script>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `tweet-button.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Integrate Google Analytics in WebHelp Classic Output

To allow your WebHelp system to benefit from Google Analytics reports, follow these steps:

1. Create a new Google Analytics account (if you do not already have one) and log on.
2. Choose the Analytics solution that fits the needs of your website.
3. Follow the on-screen instructions to obtain a **Tracking Code** that contains your *Tracking ID*.

   A **Tracking Code** looks like this:

```
<script>
 (function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
 (i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
 m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
 })(window,document,'script','//www.google-analytics.com/analytics.js','ga');

 ga('create', 'UA-XXXXXXXX-X', 'auto');
 ga('send', 'pageview');
</script>
```

4. Save the Tracking Code (obtained in the previous step) in a new HTML file called `googleAnalytics.html`.
5. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
6. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
7. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `googleAnalytics.html` file that you created earlier.
8. Click **Ok**.
9. Run the transformation scenario.

How to Integrate Google Search in WebHelp Classic Output

You can integrate Google Search into your WebHelp output.

To allow your WebHelp system to use Google Search, follow these steps:

1. Go to the Google Custom Search Engine page using your Google account.
2. Press the **Create a custom search engine** button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet.

   A Google Search script looks like this:

```
<script>
 (function()  {
  var cx =
    '000888210889775888983:8mn4x_mf-yg';
  var gcse = document.createElement('script');
  gcse.type = 'text/javascript';
  gcse.async = true;
  gcse.src = (document.location.protocol == 'https:' ?
    'https:' : 'http:') +         '//www.google.com/cse/cse.js?cx=' + cx;
  var s = document.getElementsByTagName('script')[0];
  s.parentNode.insertBefore(gcse, s);
 }
 )();
</script>
```

4. Save the script into a well-formed HTML file called `googlecse.html`.
5. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
6. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
7. Switch to the **Parameters** tab and edit the `webhelp.google.search.script` parameter to reference the `googlecse.html` file that you created earlier.

8. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a) Create an HTML file with the following content: `<div class="gcse-searchresults-only" data-queryParameterName="searchQuery" >` (you must use the *HTML5 version for the GCSE*). It is recommended that you set the `data-linkTarget` attribute value to `frm` for *frameless* versions of the WebHelp system or to `data-contentWin` for *frameset* versions of WebHelp. The default value is `_blank` and if you do not specify a value the search results will be loaded in a new window. For more information about other supported attributes, see *Google Custom Search: Supported Attributes*.
   b) Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used: `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`.
9. Click **Ok**.
10. Run the transformation scenario.

Integrating Social Media and Google Tools in WebHelp Output on page 1188

Localizing the Email Notifications of WebHelp with Feedback Systems

The feedback-enabled WebHelp systems use emails to notify users when comments are posted. These emails are based on templates stored in the WebHelp directory. The default messages are in English, French, German, and Japanese. These messages are copied into the WebHelp system deployment directory during the execution of the corresponding transformation scenario.

Suppose that you want to localize the emails into Dutch (*nl*). Follow these steps:

DocBook WebHelp Classic with Feedback

1. Create the following directory:

   [OXYGEN_INSTALL_DIR]`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl`
2. Copy all English template files from *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\en` and paste them into the directory you just created.
3. Edit the HTML files from the *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl` directory and translate the content into Dutch.
4. Start Oxygen XML Editor and edit the **DocBook WebHelp Classic with Feedback** transformation scenario.
5. In the **Parameters** tab, look for the `l10n.gentext.default.language` parameter and set its value to the appropriate language code. In our example, use the value `nl` for Dutch.

   Note: If you set the parameter to a value such as `LanguageCode-CountryCode` (for example, `en-us`), the transformation scenario will only use the language code
6. Run the transformation scenario to obtain the **WebHelp with Feedback** output.

DITA WebHelp Classic with Feedback or WebHelp Responsive with Feedback

1. Create the following directory:

   DITA-OT-DIR`\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl`
2. Copy all English template files from *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\en` and paste them into the directory you just created.
3. Edit the HTML files from the *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\php\templates\nl` directory and translate the content into Dutch.
4. Start Oxygen XML Editor and edit the **DITA Map WebHelp Classic with Feedback** or **DITA Map WebHelp Responsive with Feedback** transformation scenario.
5. In the **Parameters** tab, look for the `args.default.language` parameter and set its value to the appropriate language code. In our example, use the value `nl` for Dutch.

Note: If you set the parameter to a value such as `LanguageCode-CountryCode` (for example, `en-us`), the transformation scenario will only use the language code

6. Run the transformation scenario to obtain the **WebHelp with Feedback** output.

Localizing the Interface of WebHelp Output

You can localize the interface of WebHelp output for DITA or DocBook transformations.

Localizing the Interface of WebHelp Output (for DITA Map Transformations)

Static labels used in the WebHelp output are stored in translation files that have the *strings-lang1-lang2.xml* name format, where *lang1* and *lang2* are ISO language codes. For example, the US English labels are kept in the *strings-en-us.xml* file.

These translation files are collected from two locations:

- `DITA-OT_DIR/xsl/common` folder - DITA-OT's default translations.
- *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder - These translations are contributed by the WebHelp plugin and extend the default ones provided by DITA-OT. The labels defined in this folder take precedence over the DITA-OT default ones.

  Important: If you need to customize the translation labels, you should do this by updating the translation files found in the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder.

To localize the interface of the WebHelp output for *DITA map* transformations, follow these steps:

1. Look for the *strings-[lang1]-[lang2].xml* file in *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory (for example, the Canadian French file would be: *strings-fr-ca.xml*). If it does not exist, use the following procedure to create one:
   a) Create a new `strings-fr-ca.xml` file in the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory.
   b) Copy all the labels found in the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings-en-us.xml` and paste them into the newly created file.
   c) Copy all the labels found in the `DITA-OT_DIR/xsl/common/strings-en-us.xml` and paste them into the newly created file.
2. Translate all the labels from the above language file. Labels are stored in XML elements that have the following format: `<str name="Label name">Caption</str>`.
3. Run the predefined transformation scenario called **Run DITA OT Integrator** by executing it from the **Apply Transformation Scenario(s)** dialog box. If the *integrator* is not visible, select the **Show all scenarios** action that is available in the **Settings** drop-down menu.
4. Make sure that the new XML file that you created in the previous two steps is listed in the file *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings.xml`. In our example for the Canadian French file, it should be listed as: `<lang xml:lang="fr-ca" filename="strings-fr-ca.xml"/>`.
5. Edit any of the **DITA Map to WebHelp** transformation scenarios (with or without feedback, or the mobile version) and set the args.default.language parameter to the code of the language you want to localize (for example, *fr-ca* for Canadian French).
6. Run the transformation scenario to produce the WebHelp output.

Searching Japanese Content in WebHelp Pages on page 1193

Localizing the Interface of WebHelp Output (for DocBook Transformations)

Static labels that are used in the WebHelp output are kept in translation files in the *`[OXYGEN_INSTALL_DIR]`*`/frameworks/docbook/xsl/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder. Translation files have the *strings-lang1-lang2.xml* name format, where *lang1* and *lang2* are ISO language codes. For example, the US English text is kept in the *strings-en-us.xml* file.

To localize the interface of the WebHelp output for DocBook transformations, follow these steps:

1. Look for the *strings-[lang1]-[lang2].xml* file in `[OXYGEN_INSTALL_DIR]/frameworks/docbook/xsl/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory (for example, the Canadian French file would be: *strings-fr-ca.xml*). If it does not exist, create one starting from the *strings-en-us.xml* file.
2. Translate all the labels from the above language file. Labels are stored in XML elements that have the following format: `<str name="Label name">Caption</str>`.
3. Make sure that the new XML file that you created in the previous two steps is listed in the file `[OXYGEN_INSTALL_DIR]/frameworks/docbook/xsl/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings.xml`. In our example for the Canadian French file, it should be listed as: `<lang xml:lang="fr-ca" filename="strings-fr-ca.xml"/>`.
4. Edit any of the DocBook to WebHelp transformation scenarios (with or without feedback, or the mobile version) and set the l10n.gentext.default.language parameter to the code of the language you want to localize (for example, *fr-ca* for Canadian French).
5. Run the transformation scenario to produce the WebHelp output.

Searching Japanese Content in WebHelp Pages on page 1193

Searching Japanese Content in WebHelp Pages

To optimize the indexing of Japanese content in WebHelp pages, the Lucene Kuromoji Japanese analyzer can be used. This analyzer is included in the Oxygen XML Editor installation kit.

Activating Japanese Indexing in DITA WebHelp Systems

To activate the Japanese indexing in your WebHelp system generated from DITA content, follow these steps:

1. Set the language for your content to Japanese with one of the following two methods:
   - Edit a **DITA to WebHelp** transformation scenario and in the ***Parameters*** *tab*, set the value of the `args.default.language` parameter to `ja-jp`.
   - Set the `xml:lang` attribute on the root of the *DITA map* and the referenced topics to `ja-jp`.
2. For the analyzer to work properly, search terms that are entered into the WebHelp search text field must be separated by spaces.
3. Run the **DITA to WebHelp** transformation scenario to generate the output.

Optionally a Japanese user dictionary can be set with the *webhelp.search.japanese.dictionary parameter*.

Activating Japanese Indexing in DocBook WebHelp Systems

To activate the Japanese indexing in your WebHelp system generated from DocBook content, follow these steps:

1. Edit a **DocBook to WebHelp** transformation scenario and in the ***Parameters*** *tab*, set the value of the `l10n.gentext.default.language` parameter to `ja`.
2. Run the transformation scenario to generate the output.

Overriding XSLT Processing Step of DITA WebHelp Classic Transformations

Since WebHelp output is primarily obtained by running XSLT transformations over the DITA input files (through the **DITA Map WebHelp Classic** transformation scenarios), one customization method would be to override the default XSLT templates that are used by the WebHelp transformations.

There are two methods available to override the XSLT stylesheets implied by the WebHelp transformation.

- The first method is to use one of the ***WebHelp XSLT-import extension points*** that allow you to import an XSLT stylesheet so that it becomes part of the normal build. This method uses the same mechanism as the *DITA-*

OT XSLT-import extension points. Note that this method will affect all the outputs generated with the WebHelp system.

- The second method implies that you will *create a DITA-OT extension plugin* with a custom *transtype* and use an Ant build file to define the transformation process. The main difference from the first customization method is that you will not affect all WebHelp transformations. Only the transformations that use the declared plugin *transtype* will be affected.

WebHelp Classic XSLT-Import and XSLT-Parameter Extension Points

The WebHelp XSLT-Import extension points allows you to extend the XSLT stylesheets associated with some of the WebHelp transformation steps. The DITA-OT plug-in installer adds an XSLT import statement in the default WebHelp XSLT so that the XSLT stylesheet referenced by the extension point becomes part of the normal build.

Example:

```
<plugin id="com.oxygenxml.webhelp.classic.extension">
  <feature extension="com.oxygenxml.webhelp.classic.xsl.dita2webhelp"
           file="xsl/fixup.xsl"/>
</plugin>
```

Attention: The customizations you make by using this extension point will affect all WebHelp transformations. If you want to have a customization that is only available for a certain transformation, please use the *Overriding a WebHelp XSLT Stylesheet from an Ant Build File* method.

XSLT-Import Extension Points

The following extension points are available:

com.oxygenxml.webhelp.classic.xsl.dita2webhelp

Extension point to override the XSLT stylesheet (`dita2webhelpImpl.xsl`) that produces an HTML file for each DITA topic. Depending on the type of WebHelp transformation you are currently using, the path to this stylesheet is as follows:

- ***WebHelp Classic* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\desktop\dita2webhelpImpl.xsl`
- ***WebHelp Classic Mobile* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\mobile\dita2webhelpImpl.xsl`

com.oxygenxml.webhelp.classic.xsl.createMainFiles

Extension point to override the XSLT stylesheet (`createMainFilesImpl.xsl`) that produces the WebHelp main HTML page (`index.html`). Depending on the type of WebHelp transformation you are currently using, the path to this stylesheet is as follows:

- ***WebHelp Classic* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\desktop\createMainFilesImpl.xsl`
- ***WebHelp Classic Mobile* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\mobile\createMainFilesImpl.xsl`

com.oxygenxml.webhelp.classic.xsl.createTocXML

Extension point to override the XSLT stylesheet (`tocDita.xsl`) that produces the `toc.xml` file. This file contains information extracted from the *DITA map* and it is mainly used to construct the WebHelp Table of Contents and navigational links. The path to this stylesheet is: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\tocDita.xsl`.

XSLT-Parameter Extension Points

If your customization stylesheet declares one or more XSLT parameters and you want to control their values from the transformation scenario, you can use one of the following XSLT parameter extension points:

com.oxygenxml.webhelp.classic.xsl.dita2webhelp.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.classic.xsl.dita2webhelp*** *extension point*.

com.oxygenxml.webhelp.classic.xsl.createMainFiles.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.classic.xsl.createMainFiles*** *extension point*.

com.oxygenxml.webhelp.classic.xsl.createTocXML.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.classic.xsl.createTocXML*** *extension point*.

[DITA-OT] XSLT-Import Extension Points

[DITA-OT] XSLT-Parameter Extension Points

Overriding a WebHelp Classic XSLT Stylesheet from an Ant Build File

To create a WebHelp XSLT customization that is only available for a certain DITA OT transformation, the extension plugin should *declare a custom transtype*. The WebHelp XSLT stylesheets can be overridden from an ANT file provided by the DITA-OT extension plugin. From the Ant target associated with the plugin, you will specify a custom XSLT stylesheet that imports the original WebHelp stylesheet and add some customization templates.

The following procedure explains how to create a DITA-OT extension plugin that uses this extension method:

1. In the *`DITA-OT-DIR`*`\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.webhelp.classic.custom`).
2. Create a **plugin.xml** file (in the folder you created in step 1) that specifies a new DITA-OT `transtype` and the build file associated with the plugin. For example:

```
<plugin id="com.oxygenxml.webhelp.classic.custom">
    <feature extension="dita.conductor.target.relative" file="integrator.xml"/>
    <transtype name="webhelp-classic-custom" extends="webhelp"
      desc="WebHelp Classic Customization"/>
</plugin>
```

3. Create the **integrator.xml** file that will import the actual plugin Ant build file.

```
<project basedir="." name="Webhelp Classic Customization">
    <import file="build.xml"/>
</project>
```

4. Create the **build.xml** file that overrides the value of properties associated with the *XSLT stylesheets used to produce HTML files*. The following Ant properties can be overridden to specify your customization stylesheets:

   `args.wh.classic.topic.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce an HTML file for each topic*.

   `args.wh.classic.create.main.files.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the main HTML files*.

   `args.wh.classic.createTocXML.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the toc.xml file*. The toc.xml file contains information extracted from DITA map and it is mainly used to create the WebHelp TOC.

   For example, to customize a WebHelp Classic transformation type, the build file should look like:

```
<project basedir="." name="Webhelp Classic Customization">
 <target name="dita2webhelp-classic-custom">
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce an HTML file for each topic
   -->
   <property
     name="args.wh.classic.topic.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}
                                              /xsl/dita2webhelpCustom.xsl"/>
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce the main HTML file.
   -->
   <property
     name="args.wh.classic.create.main.files.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}
                                            /xsl/createMainFilesCustom.xsl"/>
```

```
    <!--
      Override this property if you want to customize the XSLT stylesheet
      used to produce the toc.xml file.
    -->
    <property
      name="args.wh.classic.createTocXML.xsl"
      value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}
                                            /xsl/createTocXMLCustom.xsl"/>
    <!--
      Depending on which version of WebHelp you want to customize,
      you need to delegate to different build targets:
      * dita2webhelp-mobile - when you are customizing the Webhelp Mobile
      * dita2webhelp - when you are customizing the Webhelp Classic
    -->
    <antcall target="dita2webhelp"/>
  </target>
 </project>
```

Note: Depending on which version of WebHelp you want to customize, you need to call one of the following build targets:

- **dita2webhelp** - For WebHelp Classic (with or without feedback) output.
- **dita2webhelp-mobile** - For WebHelp Classic Mobile output (deprecated).

5. Create an **xsl** directory in the plugin customization directory (that you created in step 1) to store the customized XSLT stylesheets.
6. Now that the extension plugin is created, *install it in the DITA Open Toolkit*.

Referencing the WebHelp XSLT Stylesheets from Your Customizations

Note that your customization stylesheets should import the original stylesheets that they override. To reference the WebHelp stylesheets, you can use the **plugin:com.oxygenxml.dita-ot.plugin.webhelp** prefix. This prefix is rewritten by an XML catalog to the WebHelp root directory.

Customizing the `dita2webhelp.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **dita2webhelp.xsl** stylesheet should look like:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:math="http://www.w3.org/2005/xpath-functions/math"
   exclude-result-prefixes="xs math"
   version="2.0">
   <!--
     Import the original stylesheet used to produce an HTML file for each topic.
   -->
   <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/
                                          dita/classic/dita2webhelp.xsl"/>
   <!--
     Please add your customization templates here.
   -->
</xsl:stylesheet>
```

Depending on which version of WebHelp you want to customize, you need to import one of the following XSLT stylesheets:

- **dita2webhelp** (WebHelp Classic) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/desktop/
  dita2webhelp.xsl"/>
  ```
- **dita2webhelp-mobile** (WebHelp Classic Mobile) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/mobile/
  dita2webhelp.xsl"/>
  ```

Customizing the `createMainFiles.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **createMainFiles.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the main HTML file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/
```

```
                                                desktop/createMainFiles.xsl"/>
    <!--
        Please add your customization templates here.
    -->

</xsl:stylesheet>
```

Depending on which version of WebHelp you want to customize, you need to import one of the following XSLT stylesheets:

- **dita2webhelp** (WebHelp Classic) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/desktop/
  createMainFiles.xsl"/>
  ```
- **dita2webhelp-mobile** (WebHelp Classic Mobile) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/mobile/
  createMainFiles.xsl"/>
  ```

Customizing the `tocDita.xsl` File

The XSLT stylesheet that customizes the WebHelp **tocDita.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the toc.xml file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/tocDita.xsl"/>
    <!--
        Please add your customization templates here.
    -->
</xsl:stylesheet>
```

Removing the *Previous*/*Next* Links from WebHelp Classic Output

The **Previous** and **Next** links that are created at the top area of each WebHelp Classic page can be hidden with a CSS code.

To remove these links from WebHelp Classic output, follow these steps:

1. Add the following CSS code in a custom CSS stylesheet:

   ```
   .navparent, .navprev, .navnext {
       visibility:hidden;
   }
   ```
2. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
3. Run the transformation scenario.

Search Engine Optimization for DITA WebHelp

A **DITA Map WebHelp** transformation scenario can be configured to produce a `sitemap.xml` file that is used by search engines to aid crawling and indexing mechanisms. A *sitemap* lists all pages of a WebHelp system and allows webmasters to provide additional information about each page, such as the date it was last updated, change frequency, and importance of each page in relation to other pages in your WebHelp deployment.

The structure of the `sitemap.xml` file looks like this:

```
<urlset xmlns="http://www.sitemaps.org/schemas/sitemap/0.9">
  <url>
    <loc>http://www.example.com/topics/introduction.html</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  <url>
    <loc>http://www.example.com/topics/care.html#care</loc>
```

```
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  . . .
</urlset>
```

Each page has a `<url>` element structure containing additional information, such as:

- `loc` - the URL of the page. This URL must begin with the protocol (such as `http`), if required by your web server. It is constructed from the value of the `webhelp.sitemap.base.url` parameter from the transformation scenario and the relative path to the page (collected from the `href` attribute of a `topicref` element in the *DITA map*).

  Note: The value must have fewer than 2,048 characters.
- `lastmod` (optional) - the date when the page was last modified. The date format is `YYYY-MM-DD`.
- `changefreq` (optional) - indicates how frequently the page is likely to change. This value provides general information to assist search engines, but may not correlate exactly to how often they crawl the page. Valid values are: `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, and `never`. The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.change.frequency` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.

  Note: The value `always` should be used to describe documents that change each time they are accessed. The value `never` should be used to describe archived URLs.
- `priority` (optional) - the priority of this page relative to other pages on your site. Valid values range from 0.0 to 1.0. This value does not affect how your pages are compared to pages on other sites. It only lets the search engines know which pages you deem most important for the crawlers. The first time the `sitemap.xml` file is generated, the value is set based upon the value of the `webhelp.sitemap.priority` parameter in the DITA WebHelp transformation scenario. You can change the value in each `url` element by editing the `sitemap.xml` file.

Creating and Editing the `sitemap.xml` File

Follow these steps to produce a `sitemap.xml` file for your WebHelp system, which can then be edited to fine-tune search engine optimization:

1. **Edit** the transformation scenario you currently use for obtaining your WebHelp output. This opens the **Edit DITA Scenario** dialog box.
2. Open the **Parameters** tab and set a value for the following parameters:
   - `webhelp.sitemap.base.url` - the URL of the location where your WebHelp system is deployed

     Note: This parameter is required for Oxygen XML Editor to generate the `sitemap.xml` file.
   - `webhelp.sitemap.change.frequency` - how frequently the WebHelp pages are likely to change (accepted values are: `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, and `never`)
   - `webhelp.sitemap.priority` - the priority of each page (value ranging from 0.0 to 1.0)
3. Run the transformation scenario.
4. Look for the `sitemap.xml` file in the transformation's output folder. Edit the file to fine-tune the parameters of each page, according to your needs.

Support for Right-to-Left (RTL) Oriented Languages for DITA WebHelp

To activate support for RTL (right-to-left) languages in WebHelp output, edit the *DITA map* and set the `xml:lang` attribute on its root element (`map`). The corresponding attribute value can be set for following RTL languages:

- `ar-eg` - Arabic
- `he-il` - Hebrew
- `ur-pk` - Urdu

WebHelp Skin Builder

The **WebHelp Skin Builder** is a simple, easy-to-use tool, specially designed to assist users to visually customize the look and feel of the WebHelp output. It is implemented as an online tool hosted on the Oxygen XML Editor website and allows you to experiment with various styles and colors over a documentation sample.

To be able to use the **Skin Builder**, you need:

- An Internet connection and unrestricted access to Oxygen XML Editor website.
- A late version web browser.

To start the **Skin Builder**, do one of the following:

- For DocBook or DITA WebHelp systems, use a web browser to go to *https://www.oxygenxml.com/webhelp-skin-builder*.
- For DITA WebHelp systems, you can click the **Online preview** link in the ***Skins tab*** of a DITA OT transformation scenario. In the upper section of the preview, click the **Select Skin** button, then choose **Customize Skin**.

Skin Builder Layout

The left side panel of the **Skin Builder** is divided into 3 sections:

- **Actions** - Contains the following two buttons:
  - **Import** - Opens an **Import CSS** dialog box that allows you to load a CSS stylesheet and apply it over the documentation sample.
  - **Export** - Saves all properties as a CSS file.
- **Settings** - Includes a **Highlight selection** option that helps you identify the areas affected by a particular element customization.
  - When hovering an item in the customizable elements menu, the affected sample area is highlighted with a dotted blue border.
  - When an item in the customizable elements menu is selected, the affected sample area is highlighted with a solid red border.
- **Customize** - Provides a series of customizable elements organized under four main categories:
  - Header
  - TOC Area
  - Vertical Splitter
  - Content

  For each customizable element, you can alter properties such as background color or font face. Any alteration made in the customizable elements menu is applied in real time over the sample area.

Create a Customization Skin

1. The starting point can be either one of the predefined skins or a CSS stylesheet applied over the sample using the **Import** button.
2. Use the elements in the **Customize** section to set properties that modify the look of the skin. By default, all customizable elements display a single property, but you can make more visible by clicking the + **Add** button and choosing from the available properties.

   Note: If you want to revert a particular property to its initial value, press the ↺ **Reset** button.
3. When you are happy with the skin customizations you have made, press the **Export** button. All settings will be saved in a CSS file.

Apply a Customization Skin to a DITA Map to WebHelp Classic Transformation Scenario

1. Start Oxygen XML Editor.
2. Load the *DITA map* you want to produce as a WebHelp output.
3. Edit a **DITA Map to WebHelp**-type transformation scenario. Set the previously exported CSS file in the **Custom** section of the **Skins** tab.
4. Run the transformation to obtain the WebHelp output.

Apply a Customization Skin to a DocBook to WebHelp Classic Transformation Scenario

1. Start Oxygen XML Editor.
2. Load the DocBook file you want to produce as a WebHelp output.

3. In the **Parameters** tab, set the `webhelp.skin.css` parameter to point to the previously exported CSS.
4. To customize the logo, use the following parameters: webhelp.logo.image and webhelp.logo.image.target.url.
5. Run the transformation to obtain the WebHelp output.

For more information about using the WebHelp Skin Builder, watch our video demonstration:

WebHelp Classic Runtime Additional Parameters

A deployed WebHelp system can accept the following GET parameters:

- `log` - The value can be `true` or `false` (default value). When set to `true`, it enables JavaScript debugging.
- `contextId` - The WebHelp JavaScript engine will look for this value in the `context-help-map.xml` mapping file and load the corresponding help page. For more information, see the *Context-Sensitive WebHelp System* topic.

  Note: You can use an *anchor* in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.
- `appname` - You can use this parameter in conjunction with `contextId` to search for this value in the corresponding *appname attribute value* in the mapping file.

  ```
  http://localhost/webhelp/index.html?contextId=topicID&appname=myApplication
  ```
- `toc.visible` - The value can be `true` (default value) or `false`. When set to `false`, the table of contents will be collapsed when you load the WebHelp page.
- `searchQuery` - You can use this parameter to perform a search operation when WebHelp is loaded. For example, if you want to open WebHelp showing all search results for *growing flowers*, the URL should look like this: `http://localhost/webhelp/index.html?searchQuery=growing%20flowers`.

Related Information:
Context-Sensitive WebHelp Classic System on page 1236

Context-Sensitive WebHelp Classic System

Context-sensitive help systems assist users by providing specific informational topics for certain components of a user interface, such as a button or window. This mechanism works based on mappings between a unique ID defined in the topic and a corresponding HTML page.

Generating Context-Sensitive Help

When WebHelp Classic output is generated by Oxygen XML Editor, the transformation process produces an XML mapping file called `context-help-map.xml` and copies it in the output folder of the transformation. This XML file maps an ID to a corresponding HTML page through an `appContext` element, as in the following example:

```
<map productID="oxy-webhelp" productVersion="1.1">
  <appContext helpID="myapp-functionid1" path="tasks/app-help1.html"/>
  <appContext helpID="myapp-functionid2" path="tasks/app-help1.html"/>
    .  .  .
</map>
```

The possible attributes are as follows:

`helpID`

A Unique ID provided by a topic from two possible sources (`resourceid` element or the `id` attribute that is set on the topic root element):

`resourceid`

The `resourceid` element is mapped into the `appContext` element and can be specified in either the `topicref` within a *DITA map* or in a `prolog` within a DITA topic. The `resourceid` element accepts the following attributes:

- **`appname`** - A name for the external application that references the topic. If this attribute is not specified, its value is considered to be empty (" ").

- **appid** - An ID used by an application to identify the topic.
- **id** - Specifies a value that is used by a specific application to identify the topic, but this attribute is ignored if an **appid** attribute is used. Also, starting with DITA 1.3, the **id** attribute was deprecated in favor of the **appid** attribute.

Note: Multiple `appid` values can be associated with a single `appname` value (and multiple `appname` values can be associated with a single `appid` value), but the values for both attributes work in combination to specify a specific ID for a specific application, and therefore each combination of values for the `appid` and `appname` attributes should be unique within the context of a single *root map*. For example, suppose that you need two different functions of an application to both open the same WebHelp page.

Example: `resourceid` Specified in a DITA Map

The `resourceid` element can be specified in a `topicmeta` element within a `topicref`.

```
<map title="App Help">
  <topicref href="app-help1.dita" type="task">
     <topicmeta>
       <resourceid appname="myapp" appid="functionid1"/>
       <resourceid appname="myapp" appid="functionid2"/>
     </topicmeta>
  </topicref>
</map>
```

Example: `resourceid` Specified in a DITA Topic

The `resourceid` element can be specified in a `prolog` element within a DITA topic.

```
<task id="app-help1">
  <title>My App Help</title>
  <prolog>
    <resourceid appname="myapp" appid="functionid1"/>
    <resourceid appname="myapp" appid="functionid2"/>
  </prolog>
...
</task>
```

For more information about the `resourceid` element, see *DITA Specifications: <resourceid>*.

`id`

If a `resourceid` element is not declared in the *DITA map* or DITA topic (as described above), the `id` attribute that is set on the topic root element is mapped into the `appContext` element.

Important: You should ensure that these defined IDs are unique in the context of the entire DITA project. If the IDs are not unique, the transformation scenario will display warning messages in the transformation console output and the help system will not work properly.

`path`

The path to a corresponding WebHelp page. This path is relative to the location of the `context-help-map.xml` mapping file.

`productID` (Applicable only if you are using the WebHelp Classic with Feedback transformation scenario)

The ID of the product for your documentation project.

`productVersion` (Applicable only if you are using the WebHelp Classic with Feedback transformation scenario)

The version of the product for your documentation project.

There are two ways of implementing context-sensitive help in your system:

- The XML mapping file can be loaded by a PHP script on the server side. The script receives the `contextId` value and will look it up in the XML file.
- Invoke one of the WebHelp system files `index.html` or `index_frames.html` and pass the `contextId` parameter with a specific value. The WebHelp system will automatically open the help page associated with the value of the `contextId` parameter.

  Note: The `contextId` parameter is not case sensitive.

The following example will open a *frameless* version of the WebHelp system showing the page associated with the ID `dialog1ID`:

```
index.html?contextId=dialog1ID
```

The following example will open a *frameset* version of the WebHelp system showing the page associated with the ID `view1ID`:

```
index_frames.html?contextId=view1ID
```

Tip: You can use an *anchor* in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.

Context-Sensitive Queries

You can use the URL field in your browser to search for topics in a context-sensitive WebHelp system with the assistance of the following parameters:

- `contextId` - The WebHelp JavaScript engine will look for this value in the `context-help-map.xml` mapping file and load the corresponding help page. For more information, see the *Context-Sensitive WebHelp System* topic.

  Note: You can use an *anchor* in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.
- `appname` - You can use this parameter in conjunction with `contextId` to search for this value in the corresponding *appname attribute value* in the mapping file.

  ```
  http://localhost/webhelp/index.html?contextId=topicID&appname=myApplication
  ```

WebHelp Classic Runtime Additional Parameters on page 1236

Publishing WebHelp Classic Output on a SharePoint Site

Since WebHelp output must be published locally, on the same machine where the WebHelp process is running, to publish your files directly to a SharePoint library you need to map a network drive to connect to SharePoint and change your file extensions to `.aspx`, as described in the steps below.

To publish WebHelp Classic output on a SharePoint site, follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: *https://support.microsoft.com/en-us/kb/2616712*.
2. To allow browsers to open your published files (rather than downloading them), you need to change the file extensions from `.html` to `.aspx`. Fortunately, this can be done in the transformation scenario.
   a. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
      a. For a DITA transformation, set the `args.outext` parameter to `.aspx`.
      b. For a DocBook transformation, set the `html.ext` parameter to `.aspx`.
   b. Run the transformation scenario.

WebHelp Classic Mobile System (Deprecated)

Note: The WebHelp Classic Mobile system was deprecated as of version 19.0. It is recommended that you use the more recent ***WebHelp Responsive*** *system* for a flexible mobile variant.

WebHelp is a form of online help that consists of a series of web pages (XHTML format). Its advantages include platform independence, ability to update content continuously, and it can be viewed using a regular web browser. The Oxygen XML Editor WebHelp system includes several variants to suit your specific needs. The **WebHelp Classic Mobile** variant works on multiple platforms (Android, iOS, BlackBerry, Windows Mobile) and is specially designed for mobile devices when feedback from users is not necessary. It is available for DocBook and DITA document types. The functionality of the desktop WebHelp Classic layout is preserved, it is organized in an intuitive layout, and offers table of contents, search capabilities, and index navigation.

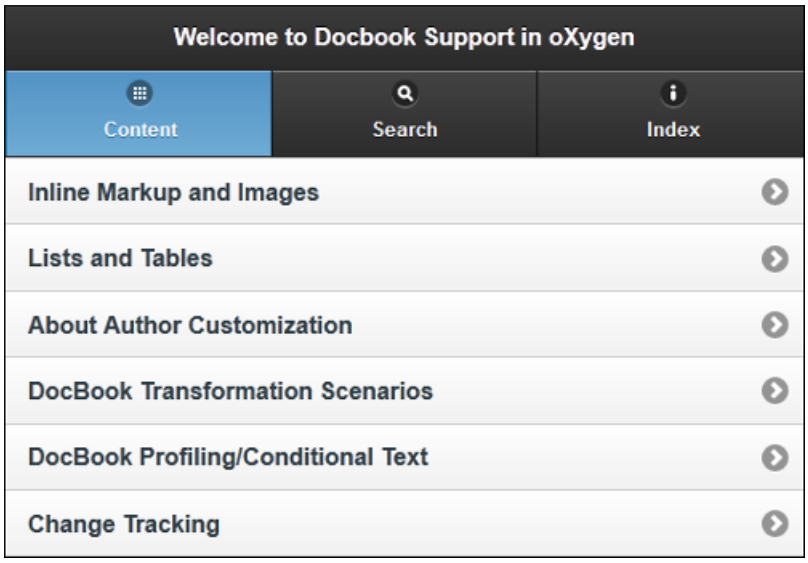

Figure 638: WebHelp Classic Mobile

Important: Due to some security restrictions in certain browsers (Google Chrome and Internet Explorer), WebHelp Classic pages loaded from the local system (through URLs of the `file:///...` format) may not work properly. We recommend that you load WebHelp Classic pages in Google Chrome or Internet Explorer only from a web server (with a URL such as `http://your.server.com/webhelp/index.html` or `http://localhost/web_pages/index.html`).

Customizing WebHelp Classic Mobile Systems

If you are familiar with CSS and coding, you can style your WebHelp output through your own custom stylesheets. You can also customize your output by modifying option and parameters in the transformation scenario. This section includes topics that explain various ways to customize your WebHelp Classic Mobile system output.

Copying Additional Resources to WebHelp Output Directory

To copy additional resources (such as JavaScript, CSS or other resources) to the output directory of a WebHelp system, follow these steps:

1. Place all your resources in the same directory.
2. Edit the WebHelp transformation scenario.
3. Go to the **Parameters** tab.
4. Edit the value for the webhelp.custom.resources parameter and set it to the absolute path of the directory in step 1.
5. Click **OK** to save the changes to the transformation scenario.
   All files from the new directory will be copied to the root of the WebHelp output directory.

Adding Custom HTML Content in WebHelp Classic Output

You can add custom HTML content in the WebHelp Classic output by inserting it in a well-formed XML file that will be referenced in the transformation scenario. This content may include references to additional JavaScript, CSS, and other types of resources, or such resources can be inserted inline within the HTML content that is inserted in the XML file.

To include custom HTML content in the WebHelp Classic output files, follow these steps:

1. Insert the HTML content in a well-formed XML file. There are several things to consider in regards to this XML file:

   a. **Well-Formedness** - If the file is not a *Well-formed XML document* (or fragments are not well-formed), the transformation will fail.

      A common use case is if you want to include several `script` or `link` elements. In this case, the XML fragment has multiple root elements and to make it well-formed, you can wrap it in an `html` element. This

element tag will be filtered out and only its children will be copied to the output documents. Similarly, you can wrap your content in `head`, `body`, `html/head`, or `html/body` elements.

b. **Referencing Resources in the XML File** - You can include references to local resources (such as JavaScript or CSS files) by using the predefined `${oxygen-webhelp-output-dir}` macro to specify their paths relative to the output directory:

```
<html>
  <script type="text/javascript" src="${oxygen-webhelp-output-dir}/js/test.js"/>
  <link rel="stylesheet" type="text/css"
        href="${oxygen-webhelp-output-dir}/css/test.css" />
</html>
```

To copy the referenced resources to the output directory, follow the procedure in: *Copying Additional Resources to WebHelp Output Directory* on page 1179.

c. **Inline JavaScript or CSS Content** - If you want to include inline JavaScript or CSS content in the XML file, it is important to place this content inside an XML comment, as in the following examples:

JavaScript:

```
<script type="text/javascript">
  <!--
    /* Include JavaScript code here. */

    function myFunction() {
      return true;
    }
  -->
</script>
```

CSS:

```
<style>
  <!--
    /* Include CSS style rules here. */

    *{
      color:red
    }
  -->
</style>
```

2. Edit the WebHelp Classic transformation scenario.
3. Go to the **Parameters** tab.
4. Edit the value of the webhelp.head.script parameter and set it to the URL of the XML file created in step 1. Your additional content will be included at the end of the `head` element of your output document.

   Note: If you want to include the content in the `body` element, use the webhelp.body.script parameter instead.
5. Click **OK** to save the changes to the transformation scenario.

Copying Additional Resources to WebHelp Output Directory on page 1179

Adding a Button in Code Snippet Areas in DITA WebHelp Classic Output

This task will get you started with how to add an action (such as a button or link) in the code snippet areas that are displayed in WebHelp Classic output created from a *DITA map* transformation. You can then attach your code that does the actual processing for the action.

Follow these steps:

1. Open the *DITA-OT-DIR*`\plugins\org.dita.xhtml\xsl\xslhtml\dita2htmlImpl.xsl` file.
2. Locate the `<xsl:template match="*[contains(@class, ' topic/pre ')]" mode="pre-fmt">` template to check the default behavior of this template.
3. Open the *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\desktop\fixup.xsl` file.
4. Create a `<xsl:template match="*[contains(@class, ' topic/pre ')]" mode="pre-fmt">` template to override the default processing.
5. This new template will include your code for creating the button. It will have the action code that does the actual processing attached to it (this can be written in JavaScript, for example).

Example of a *Select all* button:

```
<xsl:template match="*[contains(@class, ' topic/pre ')]" mode="pre-fmt">
    <button onclick="SelectText(element)">Select all</button>
    <script>
      function SelectText(element) {
        var text = document.getElementById(element);
        var range = document.body.createTextRange();
        range.moveToElementText(text);
        range.select();
      }
    </script>
  </xsl:template>
```

Adding a Favicon in WebHelp Systems

You can add a custom *favicon* to your WebHelp system by simply using a parameter in the transformation scenario to point to your *favicon* image. This is available for DITA and DocBook WebHelp systems using **WebHelp Responsive**, **WebHelp Responsive with Feedback**, **WebHelp Classic**, **WebHelp Classic with Feedback**, or **WebHelp Classic Mobile** transformation scenarios.

To add a *favicon*, follow these steps:

1. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
2. Locate the `webhelp.favicon` parameter and enter the file path that points to the image that will be use as the *favicon*.
3. Run the transformation scenario.

Adding Video and Audio Objects in DITA WebHelp Output

You can insert references to video and audio media resources (such as videos, audio clips, or embedded HTML frames) in your DITA topics and then publish them to WebHelp output. The media objects can be played directly in all HTML5-based outputs, including WebHelp systems.

To add media objects in the WebHelp output generated from DITA documents, follow the procedures below.

Adding Videos to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the video through one of the following methods:
   - Use the ***Insert Media Object*** *toolbar action*.
   - Drag (or copy) the video file from your system explorer or the ***Project*** *view* and drop (or paste) it into your document.
   - Manually add an `object` element, as in one of the following examples:

     ```
     <object outputclass="video" type="video/mp4" data="MyVideo.mp4"/>
     ```

     or, instead of the `data` attribute, you can specify the video using a parameter like this:

     ```
     <object outputclass="video">
       <param name="src" value="videos/MyVideo.mp4"/>
     </object>
     ```
2. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

   Result: The transformation converts the `object` element to an HTML5 `video` element.

   ```
   <video controls="controls"><source type="video/mp4" src="MyVideo.mp4"></source>
   </video>
   ```

Adding Audio Clips to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the audio clip through one of the following methods:
   - Use the ***Insert Media Object*** *toolbar action*.
   - Drag (or copy) the audio file from your system explorer or the ***Project*** *view* and drop (or paste) it into your document.

- Manually add an `object` element, as in one of the following examples:

```
<object outputclass="audio" type="audio/mpeg" data="MyClip.mp3"/>
```

or, instead of the `data` attribute, you can specify the video using a parameter like this:

```
<object outputclass="audio">
  <param name="src" value="audio/MyClip.mp3"/>
</object>
```

2. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

Result: The transformation converts the `object` element to an HTML5 `audio` element.

```
<audio controls="controls"><source type="audio/mpeg" src="MyClip.mp3"></source>
</audio>
```

Adding Embedded HTML Frames (such as YouTube videos) to DITA WebHelp Output

1. Edit the DITA topic and insert a reference to the embedded object by using the  ***Insert Media Object*** *toolbar action* or by manually adding an `object` element, as in one of the following examples:

```
<object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
```

or, instead of the `data` attribute, you can specify the object using a parameter like this:

```
<object outputclass="iframe">
  <param name="src" value="http://www.youtube.com/embed/m_vv2s5Trn4"/>
</object>
```

2. If you want the video to be allowed to play in full screen mode once the document is converted to XHTML output, also add an `allowfullscreen` parameter and set its value to **true**:

```
<object outputclass="iframe" data="https://www.youtube.com/embed/m_vv2s5Trn4"/>
  <param name="allowfullscreen" value="true"/>
</object>
```

Tip: If you copy the embed code from the source and paste it into the **Insert Media** dialog box (see the specific instructions: *here*), the `allowfullscreen` parameter will automatically be added and all you have to do is set the value to **true**.

3. Apply a **DITA to WebHelp** transformation scenario to obtain the output.

Result: The transformation converts the `object` element to an HTML5 `iframe` element.

```
<iframe controls="controls" src="https://www.youtube.com/embed/m_vv2s5Trn4">
</iframe>
```

For more information, see the following video demonstration:

Related Information:

Adding Video, Audio, and Embedded HTML Resources in DITA Topics on page 1830

Adding Videos in DocBook WebHelp Classic Output

You can insert references to videos in your DocBook topics and then publish them to **WebHelp Classic** output. The videos can be played directly in all HTML5-based outputs, including WebHelp systems.

To add videos in the **WebHelp Classic** output generated from DocBook documents, follow these steps:

1. Edit the DocBook document and reference the video using an `mediaobject` element, as in the following example:

```
<mediaobject>
  <videoobject>
    <videodata fileref="http://www.youtube.com/watch/v/VideoName"/>
  </videoobject>
</mediaobject>
```

2. Apply a *WebHelp* or *WebHelp with Feedback* transformation scenario to obtain the output.

Changing the Style of WebHelp Mobile Pages

You can change the style for your WebHelp Mobile pages by setting a custom theme created with a third-party tool.

To create a custom theme for WebHelp Mobile pages, use the following procedure:

1. Create a custom theme (the result will be a CSS stylesheet). Use a designer tool, such as the *ThemeRoller for jQuery Mobile*, to create your own custom theme and then download the resulting CSS stylesheet.

   Tip: If you are using ThemeRoller for jQuery Mobile, make sure you use a type C swatch.
2. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
3. Make sure that the output folder is empty.
4. Run the transformation scenario.

Change Numbering Styles for Ordered Lists

Ordered lists (`ol`) are usually numbered in XHTML output using numerals. If you want to change the numbering to alphabetical, follow these steps:

1. Define a custom `outputclass` value and set it as an attribute of the ordered list, as in the following example:

```
<ol outputclass="number-alpha">
    <li>A</li>
    <li>B</li>
    <li>C</li>
</ol>
```

2. Add the following code snippet in a custom CSS file:

```
ol.number-alpha{
    list-style-type:lower-alpha;
}
```

3. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
4. Run the transformation scenario.

Changing the Icons in a WebHelp Classic Table of Contents

You can change the icons that appear in a WebHelp Classic table of contents by assigning new image files in a custom CSS file. By default, the icons for the WebHelp Classic table of contents are defined with the following CSS codes (the first example is the icon that appears for a collapsed menu and the second for an expanded menu):

```
.hasSubMenuClosed{
    background: url('../img/book_closed16.png') no-repeat;
    padding-left: 16px;
    cursor: pointer;
}
```

```
.hasSubMenuOpened{
    background: url('../img/book_opened16.png') no-repeat;
    padding-left: 16px;
    cursor: pointer;
}
```

To assign other icons, use the following procedure:

1. Create a custom CSS file that assigns your desired icons to the `.hasSubMenuClosed` and `.hasSubMenuOpened` properties.

```
.hasSubMenuClosed{
    background: url('TOC-my-closed-button.png') no-repeat;
}
```

```
.hasSubMenuOpened{
    background: url('TOC-my-opened-button.png') no-repeat;
}
```

2. It is recommended that you store the image files in the same directory as the default icons.
   a) For DITA transformations: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\img\`.
   b) For DocBook transformations: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\img\`.
3. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a) For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b) For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
4. Run the transformation scenario.

CSS Styling to Customize WebHelp Output

One way to customize WebHelp output is to use custom CSS styling. This method can be used to make small, simple styling changes or more advanced, precise changes. To implement the styling in your WebHelp output, you simply need to create the custom CSS file and reference it in your transformation scenario. This custom file will be the final CSS to be applied so its content will override the styles in the other pre-existing CSS files.

Using CSS Inspector to Identify Content for Custom CSS File

You can use your browser's CSS inspector to identify the pertinent code in the current CSS files and you can even make changes directly in the CSS inspector to test the results so that you know exactly what content to use in your custom CSS file.

In most popular browsers (such as Chrome, Firefox, and Edge), you can access the CSS inspector by using **F12** or by selecting **Inspect Element** (or simply **Inspect**) from the contextual menu. When using Safari on Mac OS X, you must first enable the Develop menu by going to the Advanced settings and selecting **Show Develop menu in menu bar**. Then you can select **Show Web Inspector** from the Develop menu or click **Command+Option+I**.

Example: How to Change the Background Color of the Footer Bar

As a practical example, the following procedure can be used to change the background color of the footer bar in the WebHelp output of the Oxygen XML Editor User Guide:

1. Use the browser's CSS inspector to identify the current CSS code that styles the footer bar. In this particular case, the pertinent code that would be identified is:

```
.wh_footer {
  font-size: 15px;
  line-height: 1.7em;
  background-color: #000;
}
```

2. If you want to test the color you want to apply as the background of this particular element, use the browser's CSS inspector to change the value of the `background-color` attribute. After you find a suitable color, copy that new code.
3. Create a custom CSS file and paste or enter the copied code. For example:

```
.wh_footer {
  background-color: #255890;
}
```

4. Save the custom CSS file at a location of your convenience.
5. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.

a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.

6. Run the transformation scenario.

Result: Your custom CSS snippet will be applied as a final layer on top of any existing CSS rules and the output will reflect the changes you made.

Customize the Appearance of Selected Items in the Table of Contents

The appearance of selected items in the table of contents of WebHelp Classic output can be enhanced.

For example, to highlight the background of the selected item, follow these steps:

1. Locate the `toc.css` file in the following directory:
   a. For DITA transformations: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\oxygen-webhelp\resources\css`.
   b. For DocBook transformations: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\oxygen-webhelp\resources\css`.
2. Edit that CSS file, find the `menuItemSelected` class, and change the value of the `background` property.

Note: You can also overwrite the same value from your own custom CSS and then specify the path to your CSS in the transformation scenario (see step 3 in the *Changing the Icons in a WebHelp Classic Table of Contents* topic.

Customizing WebHelp Output with a Custom CSS

By creating your own custom CSS stylesheet, you can customize the look and style of WebHelp output to fit your specific needs.

To use a custom CSS in WebHelp output, follow these steps:

1. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
2. Run the transformation scenario.

Disable Caching in WebHelp Classic Output

In cases where a set of WebHelp Classic pages need to be updated on a regular basis to deliver the latest version of the documentation, the WebHelp pages should always be requested from the server upon re-loading it in a Web browser on the client side, rather than re-using an outdated *cached* version in the browser.

To disable caching in WebHelp Classic output, follow this procedure:

1. Edit the following XSL file for DITA or DocBook WebHelp systems:
   - For DITA WebHelp systems, edit the following file: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\createMainFiles.xsl`.
   - For DocBook WebHelp system, edit the following file: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\xsl\createMainFiles.xsl`.
2. Locate the following template in the XSL file: `<xsl:template name-"create-toc-common-file">` and add the following code snippet:

```
<meta http-equiv="Pragma" content="no-cache" />
<meta http-equiv="Expires" content="-1" />
```

Note: The code should look like this:

```
<html>
  <head>
    <xsl:if test="$withFrames">
    <base target="contentwin"/>
    </xsl:if>
    <meta http-equiv="Content-Type" content="text/html; charset=utf-8"/>
```

```
            <!-- Disable caching of WebHelp pages in web browser. -->
        <meta http-equiv="Pragma" content="no-cache" />
        <meta http-equiv="Expires" content="-1" />
....
```

3. Save your changes to the file.
4. Re-run your WebHelp system transformation scenario.

Editing Scoring Values of Tag Elements in Search Results

The WebHelp **Search** feature is enhanced with a rating mechanism that computes scores for every page that matches the search criteria. HTML tag elements are assigned a scoring value and these values are evaluated for the search results. Oxygen XML Editor includes a properties file that defines the scoring values for tag elements and this file can be edited to customize the values according to your needs.

To edit the scoring values of HTML tag element for enhancing WebHelp search results, follow these steps:

1. Edit the scoring properties file for DITA or DocBook WebHelp systems. The properties file includes instructions and examples to help you with your customization.
   a) For DITA WebHelp systems, edit the following file: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\indexer\scoring.properties`.
   b) For DocBook WebHelp system, edit the following file: *[OXYGEN_INSTALL_DIR]*`\frameworks\docbook\xsl\com.oxygenxml.webhelp\indexer\scoring.properties`.

   The values that can be edited in the `scoring.properties` file:

```
h1 = 10
h2 = 9
h3 = 8
h4 = 7
h5 = 6
h6 = 5
b = 5
strong = 5
em = 3
i=3
u=3
div.toc=-10
title=20
div.ignore=ignored
meta_keywords = 20
meta_indexterms = 20
meta_description = 25
shortdesc=25
```

2. Save your changes to the file.
3. Re-run your WebHelp system transformation scenario.

Exclude Certain DITA Topics from WebHelp Search Results

There are several ways to exclude certain DITA resources from your WebHelp system's search results. This is useful if you have topics in your *DITA map* structure that you do not want to be included in search results for your WebHelp system. The first method involves setting a parameter in the WebHelp transformation scenario and the second involves setting an attribute for each DITA topic reference that you want to exclude.

Transformation Parameter Method

To exclude DITA topics from WebHelp search results using a transformation parameter, follow these steps:

1. Create a simple text file that will contain your excluded file patterns. Each pattern must be on a new line. The patterns are considered to be relative to the output directory and they accept wildcards such as `'*'` (matches zero or more characters) or `'?'` (matches one character). For more information about the patterns, see *https://ant.apache.org/manual/dirtasks.html#patterns*.

   Example: Suppose that in your project, you want to exclude all files located in the `resources` directory and all files located in the `topics` directory that have a `.bak` file extension. You could create a simple text file (for example, named `exclude.properties`), and add the following lines:

```
resources/*
topics/*.bak
```

2. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.

3. Set the `webhelp.search.custom.excludes.file` parameter to specify the path to the file that contains the excluded file patterns (for example, `exclude.properties` in step 1).
4. Run the transformation scenario.

Search Attribute Method

The WebHelp **Search** engine does not index DITA topics that have the `@search` attribute set to no.

To exclude DITA topics from WebHelp search results using this attribute, follow these steps:

1. Edit the *DITA map* and for any `topicref` that you want to exclude from search results, set the `search` attribute to no.

   For example:

   ```
   <topicref href="../topics/internal-topic1.dita" search="no"/>
   ```

2. Save your changes to the *DITA map*.
3. Run your WebHelp system transformation scenario.

Flag DITA Content in WebHelp Output

Flagging content in WebHelp output involves defining a set of images that will be used for marking content across your information set.

To flag DITA content, you need to create a filter file that defines properties that will be applied on elements to be flagged. Generally, flagging is supported for *block elements* (such as paragraphs), but not for phrase-level elements within a paragraph. This ensures that the images that will flag the content are easily scanned by the reader, instead of being buried in text.

Follow this procedure:

1. Create a DITA filter file in the directory where you want to add the file. Give the file a descriptive name, such as `audience-flag-build.ditaval`.
2. Define the property of the element you want to be flagged. For example, if you want to flag elements that have the `audience` attribute set to `programmer`, the content of the DITAVAL file should look like the following example:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <val>
     <prop att="audience" val="programmer" action="flag"
    img="D:\resource\delta.gif" alt="sample alt text"/>
   </val>
   ```

   Note that for an element to be flagged, at least one attribute-value pair needs to have a property declared in the DITAVAL file.
3. Specify the DITAVAL file in the **Filters** tab of the transformation scenario.
4. Run the transformation scenario.

Integrating Social Media and Google Tools in WebHelp Output

Oxygen XML Editor includes support for integrating some of the most popular social media sites in WebHelp output.

How to Add a Facebook Like Button in WebHelp Classic Output

To add a Facebook™ *Like* widget to your WebHelp output, follow these steps:

1. Go to the *Facebook Developers* website.
2. Fill-in the displayed form, then click the **Get Code** button.
   A dialog box that contains code snippets is displayed.
3. Copy the two code snippets and paste them into a `<div>` element inside an XML file called `facebook-widget.xml`.

   Make sure you follow these rules:

   - The file must be well-formed.
   - The code for each `script` element must be included in an XML comment.

- The start and end tags for the XML comment must be on a separate line.

The content of the XML file should look like this:

```
<div id="facebook">
    <div id="fb-root"/>
    <script>
        <!--
            (function(d, s, id) {
        var js, fjs = d.getElementsByTagName(s)[0];
        if (d.getElementById(id)) return;
        js = d.createElement(s); js.id = id;
        js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
        fjs.parentNode.insertBefore(js, fjs);
        }(document, 'script', 'facebook-jssdk'));
        -->
    </script>
    <div class="fb-like" data-layout="standard" data-action="like"
        data-show-faces="true" data-share="true"/>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `facebook-widget.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Add a Google+ Button in WebHelp Classic Output

To add a *Google+* widget to your WebHelp output, follow these steps:

1. Go to the *Google Developers* website.
2. Fill-in the displayed form.
   The preview area on the right side displays the code and a preview of the widget.
3. Copy the code snippet displayed in the preview area and paste it into a `div` element inside an XML file called `google-plus-button.xml`.

   Make sure that the content of the file is well-formed.

   The content of the XML file should look like this:

```
<div id="google-plus">
  <!-- Place this tag in your head or just before your close body tag. -->
  <script src="https://apis.google.com/js/platform.js" async defer></script>

  <!-- Place this tag where you want the +1 button to render. -->
  <div class="g-plusone" data-annotation="inline" data-width="300"></div>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `google-plus-button.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

DITA Map to WebHelp Output on page 1017

How to Add Tweet Button in WebHelp Classic Output

To add a Twitter™ *Tweet* widget to your WebHelp output, follow these steps:

1. Go to the *Tweet button generator* page.
2. Fill-in the displayed form.
   The **Preview and code** area displays the code.
3. Copy the code snippet displayed in the **Preview and code** area and paste it into a `div` element inside an XML file called `tweet-button.xml`.

   Make sure you follow these rules:

   - The file must be well-formed.
   - The code for each `script` element must be included in an XML comment.
   - The start and end tags for the XML comment must be on a separate line.

   The content of the XML file should look like this:

```
<div id="twitter">
  <a href="https://twitter.com/share" class="twitter-share-button">Tweet</a>
  <script>
    <!--
      !function (d, s, id) {
      var
      js, fjs = d.getElementsByTagName(s)[0], p = /^http:/.test(d.location)
 ? 'http': 'https';
      if (! d.getElementById(id)) {
      js = d.createElement(s);
      js.id = id;
      js.src = p + '://platform.twitter.com/widgets.js';
      fjs.parentNode.insertBefore(js, fjs);
      }
      }
      (document,
      'script', 'twitter-wjs');
     -->
  </script>
</div>
```

4. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
5. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
6. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `tweet-button.xml` file that you created earlier.
7. Click **Ok**.
8. Run the transformation scenario.

How to Integrate Google Analytics in WebHelp Classic Output

To allow your WebHelp system to benefit from Google Analytics reports, follow these steps:

1. Create a new Google Analytics account (if you do not already have one) and log on.
2. Choose the Analytics solution that fits the needs of your website.
3. Follow the on-screen instructions to obtain a **Tracking Code** that contains your *Tracking ID*.

   A **Tracking Code** looks like this:

```
<script>
 (function(i,s,o,g,r,a,m){i['GoogleAnalyticsObject']=r;i[r]=i[r]||function(){
 (i[r].q=i[r].q||[]).push(arguments)},i[r].l=1*new Date();a=s.createElement(o),
 m=s.getElementsByTagName(o)[0];a.async=1;a.src=g;m.parentNode.insertBefore(a,m)
 })(window,document,'script','//www.google-analytics.com/analytics.js','ga');

 ga('create', 'UA-XXXXXXXX-X', 'auto');
 ga('send', 'pageview');
</script>
```

4. Save the Tracking Code (obtained in the previous step) in a new HTML file called `googleAnalytics.html`.

5. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
6. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
7. Switch to the **Parameters** tab and edit the `webhelp.footer.file` parameter to reference the `googleAnalytics.html` file that you created earlier.
8. Click **Ok**.
9. Run the transformation scenario.

DITA Map to WebHelp Output on page 1017

How to Integrate Google Search in WebHelp Classic Output

You can integrate Google Search into your WebHelp output.

To allow your WebHelp system to use Google Search, follow these steps:

1. Go to the Google Custom Search Engine page using your Google account.
2. Press the **Create a custom search engine** button.
3. Follow the on-screen instructions to create a search engine for your site. At the end of this process you should obtain a code snippet.

   A Google Search script looks like this:

```
<script>
 (function()  {
  var cx =
    '000888210889775888983:8mn4x_mf-yg';
  var gcse = document.createElement('script');
  gcse.type = 'text/javascript';
  gcse.async = true;
  gcse.src = (document.location.protocol == 'https:' ?
    'https:' : 'http:') +         '//www.google.com/cse/cse.js?cx=' + cx;
  var s = document.getElementsByTagName('script')[0];
  s.parentNode.insertBefore(gcse, s);
 }
 )();
</script>
```

4. Save the script into a well-formed HTML file called `googlecse.html`.
5. In Oxygen XML Editor, click the **Configure Transformation Scenario(s)** action from the toolbar (or the **Document** > **Transformation** menu.
6. Select an existing WebHelp transformation scenario (depending on your needs, it may be with or without feedback, or the mobile variant) and click the **Duplicate** button to open the **Edit Scenario** dialog box.
7. Switch to the **Parameters** tab and edit the `webhelp.google.search.script` parameter to reference the `googlecse.html` file that you created earlier.
8. You can also use the `webhelp.google.search.results` parameter to choose where to display the search results.
   a) Create an HTML file with the following content: `<div class="gcse-searchresults-only" data-queryParameterName="searchQuery" >` (you must use the *HTML5 version for the GCSE*). It is recommended that you set the `data-linkTarget` attribute value to `frm` for *frameless* versions of the WebHelp system or to `data-contentWin` for *frameset* versions of WebHelp. The default value is `_blank` and if you do not specify a value the search results will be loaded in a new window. For more information about other supported attributes, see *Google Custom Search: Supported Attributes*.
   b) Set the value of the `webhelp.google.search.results` parameter to the file path of the file you just created. If this parameter is not specified, the following code is used: `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`.
9. Click **Ok**.
10. Run the transformation scenario.

Integrating Social Media and Google Tools in WebHelp Output on page 1188

Localizing the Interface of WebHelp Output

You can localize the interface of WebHelp output for DITA or DocBook transformations.

Localizing the Interface of WebHelp Output (for DITA Map Transformations)

Static labels used in the WebHelp output are stored in translation files that have the *strings-lang1-lang2.xml* name format, where *lang1* and *lang2* are ISO language codes. For example, the US English labels are kept in the *strings-en-us.xml* file.

These translation files are collected from two locations:

- `DITA-OT_DIR/xsl/common` folder - DITA-OT's default translations.
- *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder - These translations are contributed by the WebHelp plugin and extend the default ones provided by DITA-OT. The labels defined in this folder take precedence over the DITA-OT default ones.

  Important: If you need to customize the translation labels, you should do this by updating the translation files found in the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder.

To localize the interface of the WebHelp output for *DITA map* transformations, follow these steps:

1. Look for the *strings-[lang1]-[lang2].xml* file in *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory (for example, the Canadian French file would be: *strings-fr-ca.xml*). If it does not exist, use the following procedure to create one:
   a) Create a new `strings-fr-ca.xml` file in the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory.
   b) Copy all the labels found in the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings-en-us.xml` and paste them into the newly created file.
   c) Copy all the labels found in the `DITA-OT_DIR/xsl/common/strings-en-us.xml` and paste them into the newly created file.
2. Translate all the labels from the above language file. Labels are stored in XML elements that have the following format: `<str name="Label name">Caption</str>`.
3. Run the predefined transformation scenario called **Run DITA OT Integrator** by executing it from the **Apply Transformation Scenario(s)** dialog box. If the *integrator* is not visible, select the **Show all scenarios** action that is available in the **Settings** drop-down menu.
4. Make sure that the new XML file that you created in the previous two steps is listed in the file *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings.xml`. In our example for the Canadian French file, it should be listed as: `<lang xml:lang="fr-ca" filename="strings-fr-ca.xml"/>`.
5. Edit any of the **DITA Map to WebHelp** transformation scenarios (with or without feedback, or the mobile version) and set the args.default.language parameter to the code of the language you want to localize (for example, *fr-ca* for Canadian French).
6. Run the transformation scenario to produce the WebHelp output.

Searching Japanese Content in WebHelp Pages on page 1193

Localizing the Interface of WebHelp Output (for DocBook Transformations)

Static labels that are used in the WebHelp output are kept in translation files in the *`[OXYGEN_INSTALL_DIR]`*`/frameworks/docbook/xsl/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` folder. Translation files have the *strings-lang1-lang2.xml* name format, where *lang1* and *lang2* are ISO language codes. For example, the US English text is kept in the *strings-en-us.xml* file.

To localize the interface of the WebHelp output for DocBook transformations, follow these steps:

1. Look for the *strings-[lang1]-[lang2].xml* file in *`[OXYGEN_INSTALL_DIR]`*`/frameworks/docbook/xsl/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization` directory (for example, the

Canadian French file would be: *strings-fr-ca.xml*). If it does not exist, create one starting from the *strings-en-us.xml* file.

2. Translate all the labels from the above language file. Labels are stored in XML elements that have the following format: `<str name="Label name">Caption</str>`.
3. Make sure that the new XML file that you created in the previous two steps is listed in the file *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl/com.oxygenxml.webhelp/oxygen-webhelp/resources/localization/strings.xml`. In our example for the Canadian French file, it should be listed as: `<lang xml:lang="fr-ca" filename="strings-fr-ca.xml"/>`.
4. Edit any of the DocBook to WebHelp transformation scenarios (with or without feedback, or the mobile version) and set the l10n.gentext.default.language parameter to the code of the language you want to localize (for example, *fr-ca* for Canadian French).
5. Run the transformation scenario to produce the WebHelp output.

Searching Japanese Content in WebHelp Pages on page 1193

Searching Japanese Content in WebHelp Pages

To optimize the indexing of Japanese content in WebHelp pages, the Lucene Kuromoji Japanese analyzer can be used. This analyzer is included in the Oxygen XML Editor installation kit.

Activating Japanese Indexing in DITA WebHelp Systems

To activate the Japanese indexing in your WebHelp system generated from DITA content, follow these steps:

1. Set the language for your content to Japanese with one of the following two methods:
   - Edit a **DITA to WebHelp** transformation scenario and in the ***Parameters*** *tab*, set the value of the `args.default.language` parameter to `ja-jp`.
   - Set the `xml:lang` attribute on the root of the *DITA map* and the referenced topics to `ja-jp`.
2. For the analyzer to work properly, search terms that are entered into the WebHelp search text field must be separated by spaces.
3. Run the **DITA to WebHelp** transformation scenario to generate the output.

Optionally a Japanese user dictionary can be set with the *webhelp.search.japanese.dictionary parameter*.

Activating Japanese Indexing in DocBook WebHelp Systems

To activate the Japanese indexing in your WebHelp system generated from DocBook content, follow these steps:

1. Edit a **DocBook to WebHelp** transformation scenario and in the ***Parameters*** *tab*, set the value of the `l10n.gentext.default.language` parameter to `ja`.
2. Run the transformation scenario to generate the output.

Overriding XSLT Processing Step of DITA WebHelp Classic Transformations

Since WebHelp output is primarily obtained by running XSLT transformations over the DITA input files (through the **DITA Map WebHelp Classic** transformation scenarios), one customization method would be to override the default XSLT templates that are used by the WebHelp transformations.

There are two methods available to override the XSLT stylesheets implied by the WebHelp transformation.

- The first method is to use one of the ***WebHelp XSLT-import extension points*** that allow you to import an XSLT stylesheet so that it becomes part of the normal build. This method uses the same mechanism as the *DITA-OT XSLT-import extension points*. Note that this method will affect all the outputs generated with the WebHelp system.
- The second method implies that you will *create a DITA-OT extension plugin* with a custom *transtype* and use an Ant build file to define the transformation process. The main difference from the first customization method

is that you will not affect all WebHelp transformations. Only the transformations that use the declared plugin *transtype* will be affected.

WebHelp Classic XSLT-Import and XSLT-Parameter Extension Points

The WebHelp XSLT-Import extension points allows you to extend the XSLT stylesheets associated with some of the WebHelp transformation steps. The DITA-OT plug-in installer adds an XSLT import statement in the default WebHelp XSLT so that the XSLT stylesheet referenced by the extension point becomes part of the normal build.

Example:

```
<plugin id="com.oxygenxml.webhelp.classic.extension">
  <feature extension="com.oxygenxml.webhelp.classic.xsl.dita2webhelp"
           file="xsl/fixup.xsl"/>
</plugin>
```

Attention: The customizations you make by using this extension point will affect all WebHelp transformations. If you want to have a customization that is only available for a certain transformation, please use the *Overriding a WebHelp XSLT Stylesheet from an Ant Build File* method.

XSLT-Import Extension Points

The following extension points are available:

com.oxygenxml.webhelp.classic.xsl.dita2webhelp

Extension point to override the XSLT stylesheet (`dita2webhelpImpl.xsl`) that produces an HTML file for each DITA topic. Depending on the type of WebHelp transformation you are currently using, the path to this stylesheet is as follows:

- ***WebHelp Classic* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\desktop\dita2webhelpImpl.xsl`
- ***WebHelp Classic Mobile* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\mobile\dita2webhelpImpl.xsl`

com.oxygenxml.webhelp.classic.xsl.createMainFiles

Extension point to override the XSLT stylesheet (`createMainFilesImpl.xsl`) that produces the WebHelp main HTML page (`index.html`). Depending on the type of WebHelp transformation you are currently using, the path to this stylesheet is as follows:

- ***WebHelp Classic* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\desktop\createMainFilesImpl.xsl`
- ***WebHelp Classic Mobile* Transformations** - *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\mobile\createMainFilesImpl.xsl`

com.oxygenxml.webhelp.classic.xsl.createTocXML

Extension point to override the XSLT stylesheet (`tocDita.xsl`) that produces the `toc.xml` file. This file contains information extracted from the *DITA map* and it is mainly used to construct the WebHelp Table of Contents and navigational links. The path to this stylesheet is: *DITA-OT-DIR*`\plugins\com.oxygenxml.webhelp\xsl\dita\tocDita.xsl`.

XSLT-Parameter Extension Points

If your customization stylesheet declares one or more XSLT parameters and you want to control their values from the transformation scenario, you can use one of the following XSLT parameter extension points:

com.oxygenxml.webhelp.classic.xsl.dita2webhelp.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.classic.xsl.dita2webhelp*** *extension point*.

com.oxygenxml.webhelp.classic.xsl.createMainFiles.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.classic.xsl.createMainFiles*** *extension point*.

com.oxygenxml.webhelp.classic.xsl.createTocXML.param

Use this extension point to pass parameters to the stylesheet specified using the ***com.oxygenxml.webhelp.classic.xsl.createTocXML*** *extension point*.

[DITA-OT] XSLT-Import Extension Points

[DITA-OT] XSLT-Parameter Extension Points

Overriding a WebHelp Classic XSLT Stylesheet from an Ant Build File

To create a WebHelp XSLT customization that is only available for a certain DITA OT transformation, the extension plugin should *declare a custom transtype*. The WebHelp XSLT stylesheets can be overridden from an ANT file provided by the DITA-OT extension plugin. From the Ant target associated with the plugin, you will specify a custom XSLT stylesheet that imports the original WebHelp stylesheet and add some customization templates.

The following procedure explains how to create a DITA-OT extension plugin that uses this extension method:

1. In the *`DITA-OT-DIR`*`\plugins\` folder, create a folder for this plugin (for example, `com.oxygenxml.webhelp.classic.custom`).
2. Create a **plugin.xml** file (in the folder you created in step 1) that specifies a new DITA-OT `transtype` and the build file associated with the plugin. For example:

```
<plugin id="com.oxygenxml.webhelp.classic.custom">
    <feature extension="dita.conductor.target.relative" file="integrator.xml"/>
    <transtype name="webhelp-classic-custom" extends="webhelp"
      desc="WebHelp Classic Customization"/>
</plugin>
```

3. Create the **integrator.xml** file that will import the actual plugin Ant build file.

```
<project basedir="." name="Webhelp Classic Customization">
    <import file="build.xml"/>
</project>
```

4. Create the **build.xml** file that overrides the value of properties associated with the *XSLT stylesheets used to produce HTML files*. The following Ant properties can be overridden to specify your customization stylesheets:

   `args.wh.classic.topic.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce an HTML file for each topic*.

   `args.wh.classic.create.main.files.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the main HTML files*.

   `args.wh.classic.createTocXML.xsl`

   Specify this property if you want to customize the *XSLT stylesheet used to produce the toc.xml file*. The toc.xml file contains information extracted from DITA map and it is mainly used to create the WebHelp TOC.

   For example, to customize a WebHelp Classic transformation type, the build file should look like:

```
<project basedir="." name="Webhelp Classic Customization">
 <target name="dita2webhelp-classic-custom">
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce an HTML file for each topic
   -->
   <property
     name="args.wh.classic.topic.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}
                                              /xsl/dita2webhelpCustom.xsl"/>
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce the main HTML file.
   -->
   <property
     name="args.wh.classic.create.main.files.xsl"
     value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}
                                            /xsl/createMainFilesCustom.xsl"/>
   <!--
     Override this property if you want to customize the XSLT stylesheet
     used to produce the toc.xml file.
   -->
   <property
     name="args.wh.classic.createTocXML.xsl"
```

```
      value="${dita.plugin.com.oxygenxml.webhelp.classic.custom.dir}
                                            /xsl/createTocXMLCustom.xsl"/>
    <!--
      Depending on which version of WebHelp you want to customize,
      you need to delegate to different build targets:
      * dita2webhelp-mobile - when you are customizing the Webhelp Mobile
      * dita2webhelp - when you are customizing the Webhelp Classic
    -->
    <antcall target="dita2webhelp"/>
  </target>
 </project>
```

Note: Depending on which version of WebHelp you want to customize, you need to call one of the following build targets:

- **dita2webhelp** - For WebHelp Classic (with or without feedback) output.
- **dita2webhelp-mobile** - For WebHelp Classic Mobile output (deprecated).

5. Create an **xsl** directory in the plugin customization directory (that you created in step 1) to store the customized XSLT stylesheets.
6. Now that the extension plugin is created, *install it in the DITA Open Toolkit*.

Referencing the WebHelp XSLT Stylesheets from Your Customizations

Note that your customization stylesheets should import the original stylesheets that they override. To reference the WebHelp stylesheets, you can use the **plugin:com.oxygenxml.dita-ot.plugin.webhelp** prefix. This prefix is rewritten by an XML catalog to the WebHelp root directory.

Customizing the `dita2webhelp.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **dita2webhelp.xsl** stylesheet should look like:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
   xmlns:xs="http://www.w3.org/2001/XMLSchema"
   xmlns:math="http://www.w3.org/2005/xpath-functions/math"
   exclude-result-prefixes="xs math"
   version="2.0">
   <!--
     Import the original stylesheet used to produce an HTML file for each topic.
   -->
   <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/
                                            dita/classic/dita2webhelp.xsl"/>
   <!--
     Please add your customization templates here.
   -->
</xsl:stylesheet>
```

Depending on which version of WebHelp you want to customize, you need to import one of the following XSLT stylesheets:

- **dita2webhelp** (WebHelp Classic) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/desktop/
  dita2webhelp.xsl"/>
  ```
- **dita2webhelp-mobile** (WebHelp Classic Mobile) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/mobile/
  dita2webhelp.xsl"/>
  ```

Customizing the `createMainFiles.xsl` Stylesheet

The XSLT stylesheet that customizes the WebHelp **createMainFiles.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the main HTML file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/
                                            desktop/createMainFiles.xsl"/>
    <!--
        Please add your customization templates here.
    -->

</xsl:stylesheet>
```

Depending on which version of WebHelp you want to customize, you need to import one of the following XSLT stylesheets:

- **dita2webhelp** (WebHelp Classic) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/desktop/
  createMainFiles.xsl"/>
  ```
- **dita2webhelp-mobile** (WebHelp Classic Mobile) -

  ```
  <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/mobile/
  createMainFiles.xsl"/>
  ```

Customizing the `tocDita.xsl` File

The XSLT stylesheet that customizes the WebHelp **tocDita.xsl** stylesheet should look like:

```
<?xml version="1.0" encoding="UTF-8"?>
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
    xmlns:xs="http://www.w3.org/2001/XMLSchema"
    xmlns:math="http://www.w3.org/2005/xpath-functions/math"
    exclude-result-prefixes="xs math"
    version="2.0">
    <!--
        Import the original stylesheet used to produce the toc.xml file.
    -->
    <xsl:import href="plugin:com.oxygenxml.webhelp.classic:xsl/dita/tocDita.xsl"/>
    <!--
        Please add your customization templates here.
    -->
</xsl:stylesheet>
```

Removing the *Previous*/*Next* Links from WebHelp Classic Output

The **Previous** and **Next** links that are created at the top area of each WebHelp Classic page can be hidden with a CSS code.

To remove these links from WebHelp Classic output, follow these steps:

1. Add the following CSS code in a custom CSS stylesheet:

   ```
   .navparent, .navprev, .navnext {
       visibility:hidden;
   }
   ```
2. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
   a. For a DITA transformation, set the `args.css` parameter to the path of your custom CSS file. Also, set the `args.copycss` parameter to `yes` to automatically copy your custom CSS in the output folder when the transformation scenario is processed.
   b. For a DocBook transformation, set the `html.stylesheet` parameter to the path of your custom CSS file.
3. Run the transformation scenario.

Search Engine Optimization for DITA WebHelp

A **DITA Map WebHelp** transformation scenario can be configured to produce a `sitemap.xml` file that is used by search engines to aid crawling and indexing mechanisms. A *sitemap* lists all pages of a WebHelp system and allows webmasters to provide additional information about each page, such as the date it was last updated, change frequency, and importance of each page in relation to other pages in your WebHelp deployment.

The structure of the `sitemap.xml` file looks like this:

```
<urlset xmlns="http://www.sitemaps.org/schemas/sitemap/0.9">
  <url>
    <loc>http://www.example.com/topics/introduction.html</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
  <url>
    <loc>http://www.example.com/topics/care.html#care</loc>
    <lastmod>2014-10-24</lastmod>
    <changefreq>weekly</changefreq>
    <priority>0.5</priority>
  </url>
    .   .   .
</urlset>
```

Each page has a <url> element structure containing additional information, such as:

- loc - the URL of the page. This URL must begin with the protocol (such as http), if required by your web server. It is constructed from the value of the webhelp.sitemap.base.url parameter from the transformation scenario and the relative path to the page (collected from the href attribute of a topicref element in the *DITA map*).

  Note: The value must have fewer than 2,048 characters.
- lastmod (optional) - the date when the page was last modified. The date format is YYYY-MM-DD.
- changefreq (optional) - indicates how frequently the page is likely to change. This value provides general information to assist search engines, but may not correlate exactly to how often they crawl the page. Valid values are: always, hourly, daily, weekly, monthly, yearly, and never. The first time the sitemap.xml file is generated, the value is set based upon the value of the webhelp.sitemap.change.frequency parameter in the DITA WebHelp transformation scenario. You can change the value in each url element by editing the sitemap.xml file.

  Note: The value always should be used to describe documents that change each time they are accessed. The value never should be used to describe archived URLs.
- priority (optional) - the priority of this page relative to other pages on your site. Valid values range from 0.0 to 1.0. This value does not affect how your pages are compared to pages on other sites. It only lets the search engines know which pages you deem most important for the crawlers. The first time the sitemap.xml file is generated, the value is set based upon the value of the webhelp.sitemap.priority parameter in the DITA WebHelp transformation scenario. You can change the value in each url element by editing the sitemap.xml file.

Creating and Editing the sitemap.xml File

Follow these steps to produce a sitemap.xml file for your WebHelp system, which can then be edited to fine-tune search engine optimization:

1. **Edit** the transformation scenario you currently use for obtaining your WebHelp output. This opens the **Edit DITA Scenario** dialog box.
2. Open the **Parameters** tab and set a value for the following parameters:
   - webhelp.sitemap.base.url - the URL of the location where your WebHelp system is deployed

     Note: This parameter is required for Oxygen XML Editor to generate the sitemap.xml file.
   - webhelp.sitemap.change.frequency - how frequently the WebHelp pages are likely to change (accepted values are: always, hourly, daily, weekly, monthly, yearly, and never)
   - webhelp.sitemap.priority - the priority of each page (value ranging from 0.0 to 1.0)
3. Run the transformation scenario.
4. Look for the sitemap.xml file in the transformation's output folder. Edit the file to fine-tune the parameters of each page, according to your needs.

Support for Right-to-Left (RTL) Oriented Languages for DITA WebHelp

To activate support for RTL (right-to-left) languages in WebHelp output, edit the *DITA map* and set the xml:lang attribute on its root element (map). The corresponding attribute value can be set for following RTL languages:

- ar-eg - Arabic
- he-il - Hebrew
- ur-pk - Urdu

WebHelp Classic Runtime Additional Parameters

A deployed WebHelp system can accept the following GET parameters:

- log - The value can be true or false (default value). When set to true, it enables JavaScript debugging.
- contextId - The WebHelp JavaScript engine will look for this value in the context-help-map.xml mapping file and load the corresponding help page. For more information, see the *Context-Sensitive WebHelp System* topic.

  Note: You can use an *anchor* in the contextId parameter to jump to a specific section in a document. For example, contextId=topicID#anchor.

- `appname` - You can use this parameter in conjunction with `contextId` to search for this value in the corresponding *appname attribute value* in the mapping file.

  ```
  http://localhost/webhelp/index.html?contextId=topicID&appname=myApplication
  ```
- `toc.visible` - The value can be `true` (default value) or `false`. When set to `false`, the table of contents will be collapsed when you load the WebHelp page.
- `searchQuery` - You can use this parameter to perform a search operation when WebHelp is loaded. For example, if you want to open WebHelp showing all search results for *growing flowers*, the URL should look like this: `http://localhost/webhelp/index.html?searchQuery=growing%20flowers`.

Related Information:

Context-Sensitive WebHelp Classic System on page 1236

Context-Sensitive WebHelp Classic System

Context-sensitive help systems assist users by providing specific informational topics for certain components of a user interface, such as a button or window. This mechanism works based on mappings between a unique ID defined in the topic and a corresponding HTML page.

Generating Context-Sensitive Help

When WebHelp Classic output is generated by Oxygen XML Editor, the transformation process produces an XML mapping file called `context-help-map.xml` and copies it in the output folder of the transformation. This XML file maps an ID to a corresponding HTML page through an `appContext` element, as in the following example:

```
<map productID="oxy-webhelp" productVersion="1.1">
  <appContext helpID="myapp-functionid1" path="tasks/app-help1.html"/>
  <appContext helpID="myapp-functionid2" path="tasks/app-help1.html"/>
    .  .  .
</map>
```

The possible attributes are as follows:

`helpID`

A Unique ID provided by a topic from two possible sources (`resourceid` element or the `id` attribute that is set on the topic root element):

`resourceid`

The `resourceid` element is mapped into the `appContext` element and can be specified in either the `topicref` within a *DITA map* or in a `prolog` within a DITA topic. The `resourceid` element accepts the following attributes:

- **`appname`** - A name for the external application that references the topic. If this attribute is not specified, its value is considered to be empty (" ").
- **`appid`** - An ID used by an application to identify the topic.
- **`id`** - Specifies a value that is used by a specific application to identify the topic, but this attribute is ignored if an **`appid`** attribute is used. Also, starting with DITA 1.3, the **`id`** attribute was deprecated in favor of the **`appid`** attribute.

Note: Multiple `appid` values can be associated with a single `appname` value (and multiple `appname` values can be associated with a single `appid` value), but the values for both attributes work in combination to specify a specific ID for a specific application, and therefore each combination of values for the `appid` and `appname` attributes should be unique within the context of a single *root map*. For example, suppose that you need two different functions of an application to both open the same WebHelp page.

Example: `resourceid` Specified in a DITA Map

The `resourceid` element can be specified in a `topicmeta` element within a `topicref`.

```
<map title="App Help">
  <topicref href="app-help1.dita" type="task">
     <topicmeta>
       <resourceid appname="myapp" appid="functionid1"/>
       <resourceid appname="myapp" appid="functionid2"/>
     </topicmeta>
  </topicref>
```

```
</map>
```

Example: `resourceid` Specified in a DITA Topic

The `resourceid` element can be specified in a `prolog` element within a DITA topic.

```
<task id="app-help1">
  <title>My App Help</title>
  <prolog>
    <resourceid appname="myapp" appid="functionid1"/>
    <resourceid appname="myapp" appid="functionid2"/>
  </prolog>
...
</task>
```

For more information about the `resourceid` element, see *DITA Specifications: <resourceid>*.

`id`

If a `resourceid` element is not declared in the *DITA map* or DITA topic (as described above), the `id` attribute that is set on the topic root element is mapped into the `appContext` element.

Important: You should ensure that these defined IDs are unique in the context of the entire DITA project. If the IDs are not unique, the transformation scenario will display warning messages in the transformation console output and the help system will not work properly.

`path`

The path to a corresponding WebHelp page. This path is relative to the location of the `context-help-map.xml` mapping file.

`productID` (Applicable only if you are using the WebHelp Classic with Feedback transformation scenario)

The ID of the product for your documentation project.

`productVersion` (Applicable only if you are using the WebHelp Classic with Feedback transformation scenario)

The version of the product for your documentation project.

There are two ways of implementing context-sensitive help in your system:

- The XML mapping file can be loaded by a PHP script on the server side. The script receives the `contextId` value and will look it up in the XML file.
- Invoke one of the WebHelp system files `index.html` or `index_frames.html` and pass the `contextId` parameter with a specific value. The WebHelp system will automatically open the help page associated with the value of the `contextId` parameter.

  Note: The `contextId` parameter is not case sensitive.

The following example will open a *frameless* version of the WebHelp system showing the page associated with the ID `dialog1ID`:

```
index.html?contextId=dialog1ID
```

The following example will open a *frameset* version of the WebHelp system showing the page associated with the ID `view1ID`:

```
index_frames.html?contextId=view1ID
```

Tip: You can use an *anchor* in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.

Context-Sensitive Queries

You can use the URL field in your browser to search for topics in a context-sensitive WebHelp system with the assistance of the following parameters:

- `contextId` - The WebHelp JavaScript engine will look for this value in the `context-help-map.xml` mapping file and load the corresponding help page. For more information, see the *Context-Sensitive WebHelp System* topic.

Note: You can use an *anchor* in the `contextId` parameter to jump to a specific section in a document. For example, `contextId=topicID#anchor`.

- `appname` - You can use this parameter in conjunction with `contextId` to search for this value in the corresponding *appname attribute value* in the mapping file.

```
http://localhost/webhelp/index.html?contextId=topicID&appname=myApplication
```

WebHelp Classic Runtime Additional Parameters on page 1236

Publishing WebHelp Classic Output on a SharePoint Site

Since WebHelp output must be published locally, on the same machine where the WebHelp process is running, to publish your files directly to a SharePoint library you need to map a network drive to connect to SharePoint and change your file extensions to `.aspx`, as described in the steps below.

To publish WebHelp Classic output on a SharePoint site, follow this procedure:

1. Map a network drive to connect to your SharePoint library. For more information, see: *https://support.microsoft.com/en-us/kb/2616712*.
2. To allow browsers to open your published files (rather than downloading them), you need to change the file extensions from `.html` to `.aspx`. Fortunately, this can be done in the transformation scenario.
   a. *Edit the WebHelp transformation scenario* and open the **Parameters** tab.
      a. For a DITA transformation, set the `args.outext` parameter to `.aspx`.
      b. For a DocBook transformation, set the `html.ext` parameter to `.aspx`.
   b. Run the transformation scenario.

Using the Oxygen XML WebHelp Plugin to Automate Output

Oxygen XML WebHelp plugin allows you to use a command line interface script to obtain WebHelp output from DITA and DocBook documents. Note that the Oxygen XML WebHelp plugin is a standalone product with its own licensing terms and cannot be used with a Oxygen XML Editor license.

The WebHelp output files created with the Oxygen XML WebHelp plugin are the same as the output files produced when you run DITA or DocBook to WebHelp transformation scenarios from within Oxygen XML Editor.

When an automated process is required due to the amount of output needed, do the following:

1. Install the Oxygen XML WebHelp plugin.
2. Acquire a Oxygen XML WebHelp license from *https://www.oxygenxml.com/buy_webhelp.html*.
3. Integrate the Oxygen XML WebHelp plugin with *DITA* or *DocBook*.

Oxygen XML WebHelp Plugin for DITA

To transform DITA documents using the Oxygen XML WebHelp plugin, first integrate the plugin with the DITA Open Toolkit. The purpose of the integration is to add the following transformation types to the DITA Open Toolkit:

- **webhelp-responsive** - The transformation that produces **WebHelp Responsive** and **WebHelp Responsive with Feedback** output for desktop and mobile devices.
- **webhelp** - The transformation that produces **WebHelp Classic** output for desktop.
- **webhelp-feedback** - The transformation that produces feedback-enabled **WebHelp Classic with Feedback** for desktop.
- **webhelp-mobile** - The transformations that produces **WebHelp Classic Mobile** output for mobile devices.

Integrating the Oxygen XML WebHelp Plugin with the DITA Open Toolkit

The requirements of the Oxygen XML WebHelp plugin for the DITA Open Toolkit are as follows:

- Java Virtual Machine 1.6 or newer if you want to use DITA-OT 1.8.5 or Java Virtual Machine 1.8 or newer if you want to use DITA-OT 2.5.2.
- DITA Open Toolkit 1.8.5 or 2.5.2 (includes Saxon 9.x libraries).

Note: The Oxygen XML WebHelp Plugin has only been tested with these two specific versions (**DITA-OT 1.8.5** or **DITA-OT 2.5.2**). It is possible that the plugin may work with other versions, but only the two tested versions are supported.

To integrate the Oxygen XML WebHelp plugin with the DITA Open Toolkit, follow these steps:

1. Download and install a *Java Virtual Machine* version compatible with the DITA-OT version.
2. Download and unpack the *DITA Open Toolkit* version 1.8.5 or 2.5.2.
3. Go to *Oxygen XML WebHelp website*, download the latest DITA-OT version of the installation kit, and unzip it.
4. Copy all *plugin* directories from the unpacked archive to the `plugins` directory of the DITA OT distribution. This is necessary to enable certain functionality. For example, the `com.oxygenxml.highlight` directory adds syntax highlight capabilities to your WebHelp output for `codeblock` sections that contain source code snippets (XML, Java, JavaScript).
5. If you have not already done so, *copy your license key into a licensekey.txt file* and place it in the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp` directory.
6. In the home directory of the DITA Open Toolkit, run the `startcmd.bat` script on Windows or `startcmd.sh` script on Linux/Mac OS X. In the displayed command line interface console, run `ant -f integrator.xml`.

Upgrading the Oxygen XML WebHelp Plugin for DITA OT on page 1261

Customization Example: Apply Custom Styling to an External Transformation on page 1267

DITA OT PDF Customization Plugin

Licensing the Oxygen XML WebHelp Plugin for DITA OT

To register the license for the Oxygen XML WebHelp plugin for the DITA Open Toolkit, follow these steps:

1. Open the *`DITA-OT-DIR`*`/plugins/com.oxygenxml.webhelp` directory and create a file called `licensekey.txt`.
2. In this file, copy your license key that you purchased for your Oxygen XML WebHelp plugin.

   The WebHelp transformation process reads the Oxygen XML WebHelp license key from this file. In case the file does not exit, or it contains an invalid license, an error message will be displayed.

Upgrading the Oxygen XML WebHelp Plugin for DITA OT on page 1261

Upgrading the Oxygen XML WebHelp Plugin for DITA OT

To upgrade your Oxygen XML WebHelp plugin for the DITA Open Toolkit, follow these steps:

1. Navigate to the `plugins` directory of your DITA OT distribution and delete the old Oxygen XML WebHelp plugin files (`oxygen_custom.xsl`, `oxygen_custom_html.xsl`) and directories (`com.oxygenxml.highlight`, `com.oxygenxml.media`, `com.oxygenxml.webhelp`).
2. Go to *Oxygen XML WebHelp website*, download the latest DITA-OT version of the installation kit, and unzip it.
3. Copy all *plugin* directories from the unpacked archive to the `plugins` directory of the DITA OT distribution. This is necessary to enable certain functionality. For example, the `com.oxygenxml.highlight` directory adds syntax highlight capabilities to your WebHelp output for `codeblock` sections that contain source code snippets (XML, Java, JavaScript).
4. In the home directory of the DITA Open Toolkit, run the `startcmd.bat` script on Windows or `startcmd.sh` script on Linux/Mac OS X. In the displayed command line interface console, run `ant -f integrator.xml`.

Running an External DITA Transformation Using the Oxygen XML WebHelp Plugin

There are two main ways to run a DITA to WebHelp (***webhelp-responsive***, ***webhelp***, ***webhelp-feedback***, ***webhelp-mobile***) transformation using the Oxygen XML WebHelp plugin:

Startup Script from WebHelp Plugin Method

The first method involves running the `ditaWebhelp.bat` or `ditaWebhelp.sh` startup script that comes bundled in the WebHelp plugin folder:

- `WEBHELP_PLUGIN_DIR\ditaWebhelp.bat` script file (Windows based systems)
- `WEBHELP_PLUGIN_DIR\ditaWebhelp.sh` script file (Unix/Linux based systems)

Before using the script to generate output, you must customize it to specify the paths to the Java VM, DITA Open Toolkit, and also to set the transformation type. To do this, open the script file and edit the following variables and parameters:

- `JVM_INSTALL_DIR` - Specifies the path to the Java Virtual Machine installation directory on your disk.
- `DITA_OT_INSTALL_DIR` - Specifies the path to DITA Open Toolkit installation directory on your disk.

  Note: The scripts reference the `dost-patches-DITA-1.8.jar` *JAR* file containing DITA OT 1.8.5-specific patches. If you use DITA OT 1.7, please update that reference to `dost-patches-DITA-1.7.jar`. If you use DITA OT 2.5.2, no patches are needed, so just remove the reference.
- `TRANSTYPE` - Specifies the type of the transformation you want to apply. You can set it to `webhelp-responsive`, `webhelp`, `webhelp-feedback` or `webhelp-mobile`.
- `DITA_MAP_BASE_DIR` - Specifies the path to the directory where the input *DITA map* file is located.
- `DITAMAP_FILE` - Specifies the input *DITA map* file.
- `DITAVAL_FILE` - Specifies the `.ditaval` input filter that the transformation process applies to the input *DITA map* file.
- `DITAVAL_DIR` - Specifies the path to the directory where the `.ditaval` file is located.
- `-Doutput.dir` - Specifies the output directory of the transformation.

Startup Script from DITA OT Distribution Method

The second method involves using the startup script that comes bundled with each DITA OT distribution.

DITA OT 1.8.5

For DITA Open Toolkit 1.8.5, the general instructions for running the startup script can be found here: *http://www.dita-ot.org/1.8/readme/building-output-using-cl-tool.html*.

DITA OT 2.5.2

For DITA Open Toolkit 2.5.2, the general instructions for running the startup script can be found here: *http://www.dita-ot.org/2.3/parameters/dita-command-arguments.html*.

DITA OT Startup Script Examples:

DITA-OT-DIR`\bin\[executable] -i [path_to_input.ditamap] -f [transformation_type]`

For example:

- *DITA-OT-DIR*`\bin\dita.bat -i c:\mySample.ditamap -f webhelp-responsive` (Windows based systems)
- *DITA-OT-DIR*`\bin\dita -i c:\mySample.ditamap -f webhelp-responsive` (Unix/Linux based systems)

  Note: For the `-format` (`-f`) argument, use one of the following *transformation types*: `webhelp-responsive`, `webhelp`, `webhelp-feedback` or `webhelp-mobile`.

The downside of this approach is the fact that you will lose certain small fixes and patches that Oxygen XML Editor adds to the automated DITA OT processing. For example, you may lose the ability to process DITA topics that contain entity references inside them.

Integrating the Oxygen XML WebHelp Plugin with the DITA Open Toolkit on page 1260

Customization Example: Apply Custom Styling to an External Transformation on page 1267
DITA OT PDF Customization Plugin

Additional Oxygen XML WebHelp Plugin Parameters for DITA

You can append the following parameters to the command line that runs the transformation:

`-Dwebhelp.copyright` (not available for WebHelp Responsive systems)

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

`-Dwebhelp.custom.resources`

The file path to a directory that contains resources files. All files from this directory will be copied to the root of the WebHelp output.

`-Dwebhelp.favicon`

The file path that points to an image to be used as a *favicon* in the WebHelp output.

`-Dwebhelp.footer.file` (not available for WebHelp Responsive systems)

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
  </script>
  <div data-share="true" data-show-faces="true" data-action="like"
     data-layout="standard" class="fb-like"/>
</div>
```

`-Dwebhelp.footer.include` (not available for WebHelp Responsive systems)

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, `no`. If set to `no`, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

`-Dwebhelp.google.search.results`

A file path that specifies the location of a well-formed XHTML file containing the Google Custom Search Engine element `gcse:searchresults-only`. You can use all supported attributes for this element. It is recommend to set the `linkTarget` attribute to `frm` for frameless (*iframe*) version of WebHelp or to `contentWin` for the frameset version of WebHelp. The default value for this attribute is `_blank` and the search results will be loaded in a new window. If this parameter is not specified, the following code will be used `<gcse:searchresults-only linkTarget="frm"></gcse:searchresults-only>`

`-Dwebhelp.google.search.script`

A file path that specifies the location of a well-formed XHTML file containing the Custom Search Engine script from Google.

`-Dwebhelp.logo.image.target.url` (not available for WebHelp Classic Mobile systems)

Specifies a target URL that is set on the logo image. When you click the logo image, you will be redirected to this address.

`-Dwebhelp.logo.image` (not available for WebHelp Classic Mobile systems)

Specifies a path to an image displayed as a logo in the left side of the output header.

`-Dwebhelp.product.id` (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, `mobile-phone-user-guide`, `hvac-installation-guide`).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

`-Dwebhelp.product.version` (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

`-Dwebhelp.search.japanese.dictionary`

The file path of the dictionary that will be used by the *Kuromoji* morphological engine that Oxygen XML Editor uses for indexing Japanese content in the WebHelp pages.

`-Dwebhelp.search.ranking`

If this parameter is set to `false` then the 5-star rating mechanism is no longer included in the search results that are displayed on the **Search** tab (default setting is `true`).

`-Dwebhelp.show.changes.and.comments`

When set to `yes`, user comments, replies to comments, and tracked changes are published in the WebHelp output. The default value is no.

`-Dwebhelp.sitemap.base.url`

Base URL for all the `loc` elements in the generated `sitemap.xml` file. The value of a `loc` element is computed as the relative file path from the `href` attribute of a `topicref` element from the *DITA map*, appended to this base URL value. The `loc` element is mandatory in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `sitemap.xml` file is not generated.

`-Dwebhelp.sitemap.change.frequency`

The value of the `changefreq` element in the generated `sitemap.xml` file. The `changefreq` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `changefreq` element is not added in `sitemap.xml`. Allowed values: <empty string> (default), `always`, `hourly`, `daily`, `weekly`, `monthly`, `yearly`, `never`.

`-Dwebhelp.sitemap.priority`

The value of the `priority` element in the generated `sitemap.xml` file. It can be set to any fractional number between 0.0 (least important priority) and 1.0 (most important priority). For example, 0.3, 0.5, or 0.8. The `priority` element is optional in `sitemap.xml`. If you leave this parameter set to its default empty value, then the `priority` element is not added in `sitemap.xml`.

`-Dwebhelp.skin.css` (available only for WebHelp Classic and WebHelp Classic with Feedback systems)

Path to a CSS file that sets the style theme in the output WebHelp pages. It can be one of the predefined skin CSS from the `OXYGEN_INSTALL_DIR\frameworks\docbook\xsl\com.oxygenxml.webhelp\predefined-skins` directory, or it can be a custom skin CSS generated with the *Oxygen Skin Builder* web application.

Parameters Specific to WebHelp Responsive Output (available only for WebHelp Responsive and WebHelp Responsive with Feedback systems)

`-Dwebhelp.default.collection.type`

Specifies if the **sequence** value will be used by default when the `collection-type` attribute is not specified. This option is helpful if you want to have *Next* and *Previous* navigational buttons generated for all HTML pages. Allowed values are **no** (default) and **yes**.

`-Dwebhelp.enable.search.autocomplete`

Specifies if the *Autocomplete* feature is enabled in the WebHelp search text field. The default value is `yes`.

`-Dwebhelp.fragment.after.body`

In the generated output it displays a given XHTML fragment after the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.after.logo_and_title

In the generated output it displays a given XHTML fragment after the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.after.main.page.search

In the generated output it displays a given XHTML fragment after the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.after.toc_or_tiles

In the generated output it displays a given XHTML fragment after the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.after.top_menu

In the generated output it displays a given XHTML fragment after the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.before.body

In the generated output it displays a given XHTML fragment before the page body. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.before.logo_and_title

In the generated output it displays a given XHTML fragment before the logo and title. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.before.main.page.search

In the generated output it displays a given XHTML fragment before the search field. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.before.toc_or_tiles

In the generated output it displays a given XHTML fragment before the table of contents or tiles in the main page. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.before.top_menu

In the generated output it displays a given XHTML fragment before the top menu. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.footer

In the generated output it displays a given XHTML fragment as the page footer. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.head

In the generated output it inserts a given XHTML fragment in the `<head>` element. The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.fragment.welcome

In the generated output it displays a given XHTML fragment as a welcome message (or title). The value of the parameter can be either an XHTML fragment or a path to a file that contains a well-formed XHTML fragment.

-Dwebhelp.merge.nested.topics.related.links

Specifies if the related links from nested topics will be merged with the links in the parent topic. Thus the links will be moved from the topic content to the related links component and all of the links from the same group (for example, *Related Tasks*, *Related References*, *Related Information*) are merged into a single group. The default value is `yes`.

-Dwebhelp.search.enable.pagination

Specifies whether or not search results will be displayed on multiple pages. Allowed values are `yes` or `no`.

-Dwebhelp.search.page.numberOfItems

Specifies the number of search results items displayed on each page. This parameter is only used when the **webhelp.search.enable.pagination** parameter is enabled.

-Dwebhelp.show.breadcrumb

Specifies if the breadcrumb component will be presented in the output. The default value is `yes`.

-Dwebhelp.show.child.links

Specifies if child links will be generated in the output for all topics that have subtopics. The default value is no.

-Dwebhelp.show.indexterms.link

Specifies if an icon that links to the index will be presented in the output. The default value is yes.

-Dwebhelp.show.main.page.tiles

Specifies if the tiles component will be presented in the main page of the output. For a *tree* style layout, this parameter should be set to no.

-Dwebhelp.show.main.page.toc

Specifies if the table of contents will be presented in the main page of the output. The default value is yes.

-Dwebhelp.show.navigation.links

Specifies if navigation links will be presented in the output. The default value is yes.

-Dwebhelp.show.print.link

Specifies if a print link or icon will be presented within each topic in the output. The default value is yes.

-Dwebhelp.show.side.toc

Specifies if a side table of contents will be presented on the right side of each topic in the output. The default value is yes.

-Dwebhelp.show.top.menu

Specifies if a menu will be presented at the topic of the main page in the output. The default value is yes.

-Dwebhelp.side.toc.links

Specifies which links will be included in the side table of contents. The possible values are:

- **chapter** (default) - The side TOC will include links for the current topic, its children, its siblings, and its direct ancestor (including the direct ancestor's siblings), and the parent chapter.
- **topic** - The side TOC will only include links for the current topic and its direct children.
- **all** - The side TOC will include all links.

-Dwebhelp.side.toc.tooltip.position

By default, if a topic contains a shortdesc element, its content is displayed in a tooltip when the user hovers over its link in the side table of contents. This parameter controls whether or not this tooltip is displayed and its position relative to the link. The possible values are:

- **left** (default)
- **right**
- **top**
- **bottom**
- **hidden** - The tooltip will not be displayed.

-Dwebhelp.top.menu.depth

Specifies the maximum depth level of the topics that will be included in the top menu. The default value is 2.

Note: Note that the fix.external.refs.com.oxygenxml parameter is not supported in Oxygen XML WebHelp plugin. This parameter is normally used to specify whether or not the application tries to fix such references in a temporary files folder before the DITA Open Toolkit is invoked on the fixed references.

Further Customization

If you need to further customize the transformation process, you can append other DITA-OT parameters as well. Any parameter that you want to append must follow the -D model of the above parameters. For example, to append the args.csspath parameter, use:

```
-Dargs.csspath=[CSS_FILE_PATH]
```

where [CSS_FILE_PATH] is the location of the directory that contains the CSS file.

Related Information:
DITA OT Parameter Reference

Customization Example: Apply Custom Styling to an External Transformation

Suppose that you want to apply custom styling to an external DITA transformation using the Oxygen XML WebHelp plugin for DITA OT. The following procedure provides an example of how you could achieve this using a custom CSS file and some of the *Oxygen XML WebHelp plugin parameters*.

External Transformation Customization Example

To apply your own custom styling to an external DITA transformation using Oxygen XML WebHelp plugin, follow these steps:

1. Download and install a *Java Virtual Machine* version compatible with the DITA-OT version.
2. Download and unpack the *DITA Open Toolkit* version 1.8.5 or 2.5.2.
3. Go to *Oxygen XML WebHelp website*, download the latest DITA-OT version of the installation kit, and unzip it.
4. Copy all *plugin* directories from the unpacked archive to the `plugins` directory of the DITA OT distribution. This is necessary to enable certain functionality. For example, the `com.oxygenxml.highlight` directory adds syntax highlight capabilities to your WebHelp output for `codeblock` sections that contain source code snippets (XML, Java, JavaScript).
5. If you have not already done so, *copy your license key into a licensekey.txt file* and place it in the *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp` directory.
6. In the home directory of the DITA Open Toolkit, run the `startcmd.bat` script on Windows or `startcmd.sh` script on Linux/Mac OS X. In the displayed command line interface console, run `ant -f integrator.xml`.
7. Create a new directory for your custom template (*DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita/MyCustomTemplate`).
8. Create a new directory for your custom skin (*DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita/MyCustomTemplate/variants/tree/MyCustomSkin`).
9. Copy the *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita/bootstrap/variants/tree/light/skin.css` file to the custom skin directory you just created (*DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita/MyCustomTemplate/variants/tree/MyCustomSkin`).
10. Copy the *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita/bootstrap/variants/tree/light/resources` directory to the custom skin directory you just created (*DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita/MyCustomTemplate/variants/tree/MyCustomSkin`).
11. Use your system command console to run a command in the *DITA-OT-DIR*`/bin` folder that will invoke the external transformation and include the *Oxygen XML WebHelp plugin parameters* that you desire for your customization.

    For example:
    ```
    dita.bat -i c:\myMap.ditamap -f webhelp-responsive
    -Dwebhelp.responsive.template.name=MyCustomTemplate -
    Dwebhelp.responsive.variant.name=tree -Dwebhelp.responsive.skin.name=MyCustomSkin
    -Dargs.breadcrumbs=yes -Dwebhelp.logo.image=c:\Mylogo.png -
    Dwebhelp.show.side.toc=no -Dwebhelp.show.top.menu=yes -o c:\MyOutputDirectory
    ```
12. Check the output directory to make sure it now contains your custom skin directory.
13. Modify the *DITA-OT-DIR*`/plugins/com.oxygenxml.webhelp/templates/dita/MyCustomTemplate/variants/tree/MyCustomSkin/skin.css` file according to your needs and check the output to make sure your custom styles are applied properly.

Integrating the Oxygen XML WebHelp Plugin with the DITA Open Toolkit on page 1260

Configuring the Comment Database for DITA WebHelp Systems with Feedback

If you run the ***webhelp-responsive*** *or* ***webhelp-feedback*** transformation using the WebHelp plugin, you need to configure the database that holds the user comments.

The instructions for configuring the database are presented in the `installation.html` file, located at: `[DITA_MAP_BASE_DIR]/out/[TRANSFORM_TYPE]/oxygen-webhelp/resources`. The `installation.html` file is created by the transformation process.

Building Oxygen XML WebHelp Output on Jenkins

This procedure assumes that you have already *integrated, configured, and registered the WebHelp plugin with the DITA Open Toolkit*.

To integrate WebHelp output with the Jenkins continuous integration tool, follow these steps:

1. Create a Maven project to incorporate the DITA-OT that already integrates Oxygen XML WebHelp.
2. Go to the root of your Maven project and edit the `pom.xml` file to include the following fragment:

```
<properties>
  <oxygen-webhelp>${basedir}/tools/DITA-OT1.8.5/
       plugins/com.oxygenxml.webhelp</oxygen-webhelp>
</properties>

<plugin>
  <artifactId>exec-maven-plugin</artifactId>
  <groupId>org.codehaus.mojo</groupId>
  <executions>
    <execution><!-- Run our version calculation script -->
      <id>Version Calculation</id>
      <phase>generate-sources</phase>
      <goals>
        <goal>exec</goal>
      </goals>
      <configuration>
        <executable>${oxygen-webhelp}/ditaWebhelp.bat</executable>
      </configuration>
    </execution>
  </executions>
</plugin>
```

   Note: In the fragment above it is assumed that you are using DITA-OT version 1.8.5. If you are using another version, please adjust the path accordingly.
3. Go to the Jenkins top page and *create a new Jenkins job*. Configure this job to suit your particular requirements, such as the build frequency and location of the Maven project.

Building Oxygen XML WebHelp Output on Travis CI

This topic assumes you have a DITA project hosted on a GitHub public or private repository.

The goal of this tutorial is to help you setup a Travis continuous integration job that automatically publishes your DITA project to *GitHub pages* after every commit. The published website will contain a feedback link on each page that would allow a contributor to easily suggest changes to the documentation by creating a pull request on GitHub with just a few clicks.

Enable the Travis CI Build

1. *Sign in to Travis CI* with your GitHub account, accepting the GitHub *access permissions confirmation*.
2. Once you are signed in, and you have synchronized your GitHub repositories, go to your *profile page* and enable Travis CI for the repository you want to build.

Configure the Travis CI Build in your GitHub Project

1. Checkout your GitHub project locally.
2. Copy the `.travis` folder from *here* to the root directory of your project.
3. In the root of your GitHub project, add a file called `.travis.yml` with the following content:

```
language: dita
install:
  - echo "Installed"
script:
  - sh .travis/publish.sh
after_success:
  - sh .travis/deploy.sh
env:
  global:
    - DITAMAP=/path/to/your/ditamap/file
    - DITAVAL=/path/to/your/ditaval/file
    - ANT_OPTS=-Xmx1024M
```

Note: Replace `/path/to/your/ditamap/file` and `/path/to/your/ditaval/file` with the appropriate paths to your *DITA map* and `ditaval` files.

4. Create a GitHub personal access token by following *this procedure*.
5. *Define an environment variable in the repository settings* that has the name `GH_TOKEN` and the value equal with the GitHub personal access token created earlier.

Register Your License Key

1. Edit your `.gitignore` file (or create it if it does not already exist) and add the following line:

```
licenseKey.txt
```

2. Copy your WebHelp license to the root of your GitHub project in a file called `licenseKey.txt`.

   Important: The `licenseKey.txt` file should not be committed to GitHub as it contains a license key that is issued only to you.
3. *Encrypt the license key file* and **add** it to the `.travis.yml` configuration file. This way only the Travis CI server will be able to decrypt it during the build process.

Commit to GitHub

1. Commit the following files and folders and push the commit to GitHub:

```
git add .gitignore licenseKey.txt.enc .travis.yml .travis/
git commit -m "Set up the Travis CI publishing system"
git push
```

2. Create a `gh-pages` branch in your GitHub project where the WebHelp output will be published. You can follow the procedure *here*.

Oxygen XML WebHelp Plugin for DocBook

To transform DocBook documents using the Oxygen XML WebHelp plugin, first integrate the plugin with the DocBook XSL distribution. The purpose of the integration is to add the following transformation types to the DocBook XSL distribution:

- **webhelp** - The transformation that produces **WebHelp Classic** output for desktop.
- **webhelp-feedback** - The transformation that produces feedback-enabled **WebHelp Classic with Feedback** for desktop.
- **webhelp-mobile** - The transformations that produces **WebHelp Classic Mobile** output for mobile devices.
- **webhelp-responsive** - The transformation that produces **WebHelp Responsive** and **WebHelp Responsive with Feedback** output for desktop and mobile devices.

Integrating the Oxygen XML WebHelp Plugin with the DocBook XSL Distribution

The WebHelp plugin transformations run as an Ant build script. The requirements are:

- Ant 1.8 or later
- Java Virtual Machine 1.6 or later
- DocBook XSL 1.78.1 or later
- Saxon 6.5.5
- Saxon 9.1.0.8

To integrate the Oxygen XML WebHelp plugin with the DocBook XSL distribution, follow these steps:

1. Download and install a *Java Virtual Machine* 1.6 or later.
2. Download and install *Ant 1.8.* or later.
3. Download the *DocBook XSL 1.78.1* stylesheets and unzip them in a separate directory.
4. Go to the *Oxygen XML WebHelp website*, download the *WebHelp for DocBook* distribution, and unzip it in the DocBook XSL directory that was created in step 3.
   The DocBook XSL directory should now contain a new subdirectory named `com.oxygenxml.webhelp.classic` and two new files, `oxygen_custom.xsl` and `oxygen_custom_html.xsl`.

5. If you have not already done so, *copy your license key into a licensekey.txt file* and place it in the `com.oxygenxml.webhelp.classic` directory.
6. Download and unzip *saxon6-5-5.zip* on your computer.
7. Download and unzip *saxonb9-1-0-8j.zip* on your computer.

Licensing the Oxygen XML WebHelp Plugin for DocBook

To register the license for the Oxygen XML WebHelp plugin for the DocBook XSL distribution, follow these steps:

1. Create a `licenseKey.txt` file in the `com.oxygenxml.webhelp` subdirectory of the DocBook XSL directory.
2. In this file, copy the license key that you purchased for your Oxygen XML WebHelp plugin.

   The WebHelp transformation process reads the Oxygen XML Editor license key from this file. If the file does not exit, or it contains an invalid license, an error message is displayed.

Upgrading the Oxygen XML WebHelp Plugin for DocBook

To upgrade your Oxygen XML WebHelp plugin for DocBook, follow these steps:

1. Navigate to the *[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl` directory and delete the old Oxygen XML WebHelp plugin files (`oxygen_custom.xsl`, `oxygen_custom_html.xsl`) and directory (`com.oxygenxml.webhelp`).
2. Go to *Oxygen XML WebHelp website*, download the latest DocBook version of the installation kit, and unzip it in the DocBook XSL directory (*[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/xsl`).
   The DocBook XSL directory should now contain a new subdirectory named `com.oxygenxml.webhelp` and two new files, `oxygen_custom.xsl` and `oxygen_custom_html.xsl`.

Running an External DocBook Transformation Using the WebHelp Plugin

To run a DocBook to WebHelp (***webhelp, webhelp-feedback, webhelp-mobile***) transformation using the Oxygen XML WebHelp plugin, use:

- The `docbook.bat` script file for Windows based systems.
- The `docbook.sh` script file for Unix/Linux based systems.

  Note: You can call these files in an automated process or from the command line.

The `docbook.bat` and the `docbook.sh` files are located in the home directory of the Oxygen XML WebHelp Plugin. Before using them to generate an WebHelp system, customize them to match the paths to the JVM, DocBook XSL distribution and Saxon engine, and also to set the transformation type. To do this, open a script file and edit the following variables:

- `JVM_INSTALL_DIR` - Specifies the path to the Java Virtual Machine installation directory on your disk.
- `ANT_INSTALL_DIR` - Specifies the path to the installation directory of Ant.
- `SAXON_6_DIR` - Specifies the path to the installation directory of Saxon 6.5.5.
- `SAXON_9_DIR` - Specifies the path to the installation directory of Saxon 9.1.0.8.
- `DOCBOOK_XSL_DIR` - Specifies the path to the installation directory of the DocBook XSL distribution.
- `TRANSTYPE` - Specifies the type of the transformation you want to apply. You can set it to `webhelp`, `webhelp-feedback` and `webhelp-mobile`.
- `INPUT_DIR` - Specifies the path to the input directory, containing the input XML file.
- `XML_INPUT_FILE` - Specifies the name of the input XML file.
- `OUTPUT_DIR` - Specifies the path to the output directory where the transformation output is generated.
- `DOCBOOK_XSL_DIR_URL` - Specifies the path to the directory of the DocBook XSL distribution in URL format.

Additional Oxygen XML WebHelp Plugin Parameters for DocBook

You can append the following parameters to the command line that runs the transformation:

`-Dwebhelp.copyright`

Adds a small copyright text that appears at the end of the **Table of Contents** pane.

`-Dwebhelp.favicon`

The file path that points to an image to be used as a *favicon* in the WebHelp output.

-Dwebhelp.footer.file

Path to an XML file that includes the footer content for your WebHelp output pages. You can use this parameter to integrate social media features (such as widgets for Facebook™, Twitter™, Google Analytics, or Google+™). The file must be well-formed, each widget must be in separate `div` or `span` element, and the code for each `script` element is included in an XML comment (also, the start and end tags for the XML comment must be on a separate line). The following code exert is an example for adding a Facebook™ widget:

```
<div id="facebook">
  <div id="fb-root"/>
  <script>
    <!-- (function(d, s, id) { var js, fjs = d.getElementsByTagName(s)[0];
      if (d.getElementById(id)) return;
      js = d.createElement(s); js.id = id;
      js.src = "//connect.facebook.net/en_US/sdk.js#xfbml=1&version=v2.0";
      fjs.parentNode.insertBefore(js, fjs); }
       (document, 'script', 'facebook-jssdk')); -->
    </script>
    <div data-share="true" data-show-faces="true" data-action="like"
       data-layout="standard" class="fb-like"/>
</div>
```

-Dwebhelp.footer.include

Specifies whether or not to include footer in each WebHelp page. Possible values: `yes`, no. If set to no, no footer is added to the WebHelp pages. If set to `yes` and the `webhelp.footer.file` parameter has a value, then the content of that file is used as footer. If the `webhelp.footer.file` has no value then the default Oxygen XML Editor footer is inserted in each WebHelp page.

-Dwebhelp.product.id (available only for Feedback-enabled systems)

This parameter specifies a short name for the documentation target, or product (for example, `mobile-phone-user-guide`, `hvac-installation-guide`).

Note: You can deploy documentation for multiple products on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

-Dwebhelp.product.version (available only for Feedback-enabled systems)

Specifies the documentation version number (for example, 1.0, 2.5, etc.). New user comments are bound to this version.

Note: Multiple documentation versions can be deployed on the same server.

Restriction: The following characters are not allowed in the value of this parameter: `< > / \ ' ( ) { } = ; * % + &`.

If you need to further customize your transformation, other DocBook XSL parameters can be appended. Any parameter that you want to append must follow the `-D` model of the above parameters. For example, you can append the `html.stylesheet` parameter in the following form:

```
-Dhtml.stylesheet=/path/to/directory/of/stylesheet.css
```

Configuring the Comment Database for DocBook WebHelp Classic with Feedback

If you run the ***webhelp-feedback*** transformation using the WebHelp plugin, you need to configure the database that holds the user comments. The instructions for configuring the database are presented in the `installation.html` file, located at: `[OUTPUT_DIR]/oxygen-webhelp/resources/installation.html`. The `installation.html` file is created by the transformation process.

Working with XPath Expressions

10

Topics:

- *XPath Toolbar*
- *XPath Builder View*
- *XPath Expression Results View*
- *XPath and XML Catalogs*
- *XPath Prefix Mapping*

XPath is a language for addressing specific parts of an XML document. XPath, such as the Document Object Model (DOM), models an XML document as a tree of nodes. An XPath expression is a mechanism for navigating through and selecting nodes from the XML document. An XPath expression is, in a way, analogous to an SQL query used to select records from a database.

There are various types of nodes, including element nodes, attribute nodes, and text nodes. XPath defines a way to compute a string-value for each type of node.

XPath defines a library of standard functions for working with strings, numbers and boolean expressions.

Examples:

- `child::*` - Selects all children of the root node.
- `.//name` - Selects all elements having the name "name", descendants of the current node.
- `/catalog/cd[price>10.80]` - Selects all the `cd` elements that have a price element with a value larger than 10.80.

To find out more about XPath, go to *http://www.w3.org/TR/xpath*.

Related Information:

Content Completion in XPath Expressions on page 728

Find/Replace in Multiple Files on page 685

Find/Replace Dialog Box on page 683

XPath Toolbar

XPath is a query language for selecting nodes from an XML document. To use XPath expressions effectively, you need a good understanding of *the XPath Core Function Library*.

XPath Toolbar

Oxygen XML Editor provides an XPath toolbar to let you query XML documents fast and easy using XPath expressions.

Figure 639: XPath Toolbar

The XPath toolbar includes the following features:

XPath version chooser drop-down menu

You can choose the XPath version from the drop-down menu available in the left side of the toolbar. Available options include **XPath 1.0**, **XPath 2.0**, **XPath 2.0 SA**, **XPath 3.0**, **XPath 3.0 SA**.

Note: The results returned by XPath 2.0 SA and XPath 3.0 SA have a location limited to the line number of the start element (there are no column information and no end specified).

Warning: Oxygen XML Editor uses Saxon to execute XPath 3.0 expressions, but implements a part of the 3.0 functions. When using a function that is not implemented, Oxygen XML Editor can return a compilation error.

XPath scope menu

Oxygen XML Editor allows you to define a scope for which the XPath operation will be executed. You can choose where the XPath expression will be executed:

- **Current file** - Current selected file only.
- **Project** - All the files in the project.
- **Selected project resources** - The files selected in the project.
- **All opened files** - All files opened in the application.
- **Current DITA Map hierarchy** - All resources referenced in the currently selected *DITA map*, opened in the ***DITA Maps Manager*** *view*.
- **Opened archive** - Files open in the ***Archive Browser*** *view*.
- **Working sets** - The selected *working sets*.

At the bottom of the scope menu the following scope configuration actions are available:

- **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called *working sets*.
- **XPath file filter** - You can filter the files from the selected scope for which the XPath expression will be executed. By default, the XPath expression will be executed only on XML files, but you can also define a set of patterns that will filter out files from the current scope. If you select the **Include archive** option, the XPath expression will be also executed on the files in any archive (including EPUB and DocX) found at the current scope.

History drop-down list

The XPath combo box keeps a history of the last 15 expressions that were used so that you can easily choose them again.

Switch to XPath Builder View

Opens the ***XPath Builder*** *view*.

Settings menu

The following actions are available in this drop-down menu:

- **Update on cursor move** - When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed.
- **Evaluate as you type** - When you select this option, the XPath expression you are composing is evaluated in real time.

  Note: The **Evaluate as you type** option and the automatic validation are disabled when you edit *huge documents* or when the scope is other than **Current file**.
- **Options** - Opens the Preferences page of the currently selected processing engine.

Note: During the execution of an XPath expression, the XPath toolbar displays a **Stop** button. Press this button to stop the XPath execution.

When you type expressions longer than 60 characters, a dialog box opens that offers you the possibility to switch to the ***XPath Builder*** *view*.

Related Information:

XPath Expression Results View on page 1276

XPath Builder View

The **XPath/XQuery Builder** view allows you to compose complex XPath expressions and execute them over the currently edited XML document. For XPath 2.0 / 3.0, you can use the doc( ) function to specify the source file for which the expressions are executed. When you connect to a database, the expressions are executed over that database. If you are using the **XPath/XQuery Builder** view and the current file is an XSLT document, Oxygen XML Editor executes the expressions over the XML document in the associated scenario.

If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu. You can also open it simply by pressing the **Switch to XPath Builder View** button that is located on the *XPath toolbar*.

The upper part of the view contains the following actions:

XPath version chooser drop-down menu

A drop-down menu that allows you to select the type of the expression you want to execute. You can choose between:

- XPath 1.0 (Xerces-driven)
- XPath 2.0, XPath 2.0SA, XPath 3.0, XPath 3.0SA, XQuery 1.0, XQuery 3.0, Saxon-HE XQuery, Saxon-PE XQuery, or Saxon-EE XQuery (all of them are Saxon-driven)
- Custom connection to XML databases that can execute XQuery expressions

  Note: The results returned by XPath 2.0 SA and XPath 3.0 SA have a location limited to the line number of the start element (there are no column information and no end specified).

  Note: Oxygen XML Editor uses Saxon to execute XPath 3.0 expressions. Since Saxon implements a part of the 3.0 functions, when using a function that is not implemented, Oxygen XML Editor returns a compilation error.

Execute XPath button

Use this button to start the execution of the XPath or XQuery expression you are editing. The result of the execution is displayed in the ***Results*** *view*.

Favorites button

Allows you to save certain expressions that you can later reuse. To add an expression as a favorite, press the star button and enter a name for it. The star turns yellow to confirm that the expression was saved. Expand the drop-down menu next to the star button to see all your favorites. Oxygen XML Editor automatically groups favorites in folders named after the method of execution.

History drop-down menu

Keeps a list of the last 15 executed XPath expressions. Use the **Clear history** action from the bottom of the list to remove them.

Settings drop-down menu

Contains the following three options:

- **Update on cursor move** - When selected and you navigate through a document, the XPath expression corresponding to the XML node at the current cursor position is displayed.
- **Evaluate as you type** - When you select this option, the XPath expression you are composing is evaluated in real time.

  Note: The **Evaluate as you type** option and the automatic validation are disabled when you edit *huge documents* or when the scope is other than **Current file**.
- **Options** - Opens the Preferences page of the currently selected processing engine.

XPath scope menu

Oxygen XML Editor allows you to define a scope for which the XPath operation will be executed. You can choose where the XPath expression will be executed:

- **Current file** - Current selected file only.

- **Project** - All the files in the project.
- **Selected project resources** - The files selected in the project.
- **All opened files** - All files opened in the application.
- **Current DITA Map hierarchy** - All resources referenced in the currently selected *DITA map*, opened in the ***DITA Maps Manager*** *view*.
- **Opened archive** - Files open in the ***Archive Browser*** *view*.
- **Working sets** - The selected *working sets*.

At the bottom of the scope menu the following scope configuration actions are available:

- **Configure XPath working sets** - Allows you to configure and manage collections of files and folders, encapsulated in logical containers called *working sets*.
- **XPath file filter** - You can filter the files from the selected scope for which the XPath expression will be executed. By default, the XPath expression will be executed only on XML files, but you can also define a set of patterns that will filter out files from the current scope. If you select the **Include archive** option, the XPath expression will be also executed on the files in any archive (including EPUB and DocX) found at the current scope.

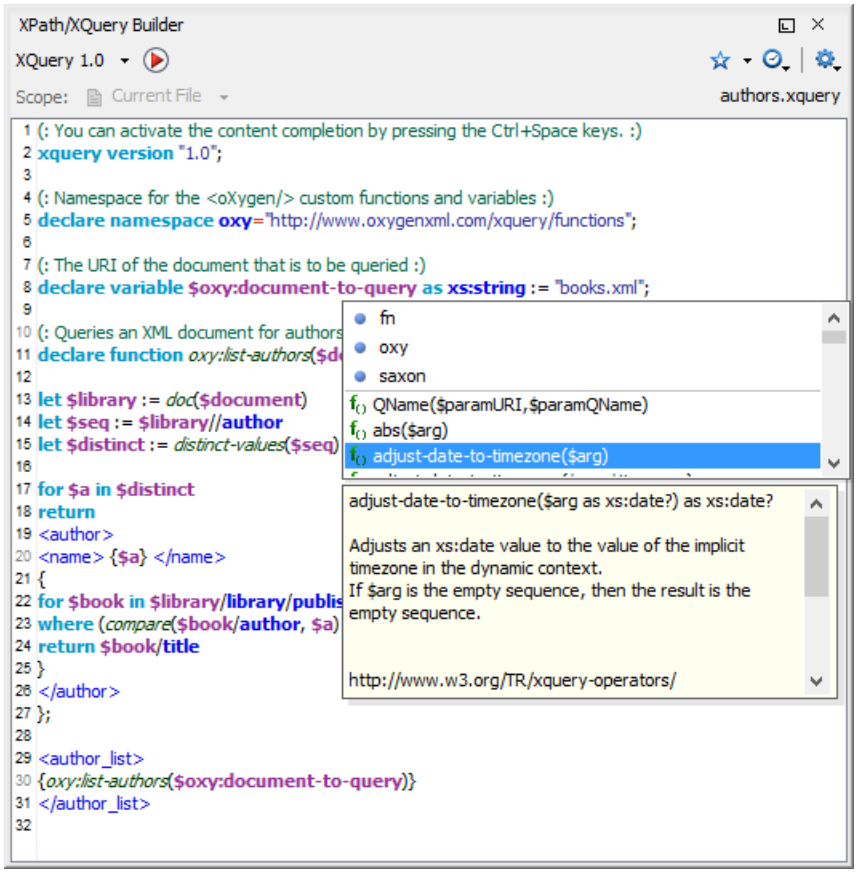

Figure 640: XPath/XQuery Builder View

While you edit an XPath or XQuery expression, Oxygen XML Editor assists you with the following features:

- *Content Completion Assistant* - It offers context-dependent proposals and takes into account the cursor position in the document you are editing. The set of functions proposed by the *Content Completion Assistant* also depends on the engine version. Select the engine version from the drop-down menu available in the toolbar.

- Syntax Highlighting - Allows you to identify the components of an expression. To customize the colors of the components of the expression, *open the **Preferences** dialog box **(Options** > **Preferences)*** and go to ***Editor** > **Syntax Highlight***.
- Automatic validation of the expression as you type.

  Note: When you type invalid syntax a red serrated line underlines the invalid fragments.
- Function signature and documentation balloon, when the cursor is located inside a function.

The usual edit actions (**Cut**, **Copy**, **Paste**, **Select All**, **Undo**, **Redo**) are available in the contextual menu of the top editable part of the view.

Related Information:

XPath Expression Results View on page 1276

XPath Expression Results View

When you run an XPath expression, Oxygen XML Editor displays the results of its execution in the ***Results** view*.

This view contains the following columns:

- **Description** - The result thatOxygen XML Editor displays when you run an XPath expression.
- **XPath location** - The path to the matched node.
- **Resource** - The name of the document that you run the XPath expression on.
- **System ID** - The path to the document itself.
- **Location** - The location of the result in the document.

To arrange the results depending on a column, click its header. To group the results by their resource, or by their system ID, right-click the header of any column in the **Results** view and select **Group by "Resource"** or **Group by "System ID"**. If no information regarding location is available, Oxygen XML Editor displays **Not available** in the **Location** column. Oxygen XML Editor displays the results in a valid XPath expression format.

```
- /node[value]/node[value]/node[value] -
```

The **Results** view also includes various toolbar and contextual menu actions. For more information, see *Results View* on page 224.

Example:

The following snippets are taken from a DocBook book based on the DocBook XML DTD. The book contains a number of chapters. To return all the chapter nodes of the book, enter `//chapter` in the XPath expression field and press **(Enter)**. This action returns all the `chapter` nodes of the DocBook book in the **Results View**. Click a record in the **Results View** to locate and highlight its corresponding chapter element and all its children nodes in the document you are editing.

To find all `example` nodes contained in the `sect2` nodes of a DocBook XML document, use the following XPath expression: `//chapter/sect1/sect2/example`. Oxygen XML Editor adds a result in the **Results View** for each `example` node found in any `sect2` node.

For example, if the result of the above XPath expression is:

```
- /chapter[1]/sect1[3]/sect2[7]/example[1]
```

it means that in the edited file, the `example` node is located in the first chapter, third section level one, seventh section level 2.

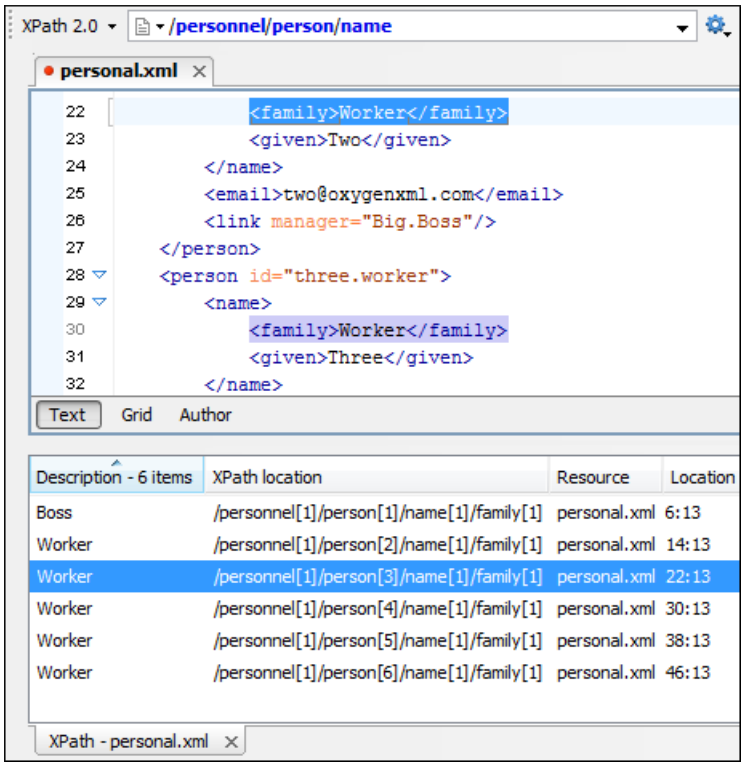

Figure 641: XPath Results Highlighted in Editor Panel with Character Precision

XPath and XML Catalogs

The evaluation of the XPath expression tries to resolve the locations of documents referenced in the expression through *XML Catalogs*. These catalogs are configured in the ***XML Catalog*** *preferences* pages and the ***XML Parser*** *preferences*.

Example:

As an example, consider the evaluation of the `collection(URIofCollection)` function (XPath 2.0). To resolve the references from the files returned by the `collection()` function with an *XML catalog*, specify the class name of the catalog-enabled parser for parsing these collection files. The class name is *ro.sync.xml.parser.CatalogEnabledXMLReader*. Specify it as it follows:

```
let $docs := collection(iri-to-uri(
   "file:///D:/temp/test/XQuery-catalog/mydocsdir?recurse=yes;select=*.xml;
   parser=ro.sync.xml.parser.CatalogEnabledXMLReader"))
```

XPath Prefix Mapping

To define default mappings between prefixes (that you can use in the *XPath toolbar*) and namespace URIs go to the ***XPath*** *preferences page* and enter the mappings in the **Default prefix-namespace mappings** table. The same preferences panel allows you to configure the default namespace used in XPath 2.0 expressions.

Important: If you define a default namespace, Oxygen XML Editor binds this namespace to the first free prefix from the list: `default`, `default1`, `default2`, and so on. For example, if you define the default namespace `xmlns="something"` and the prefix `default` is not associated with another namespace, you can match tags without prefix in an XPath expression typed in the XPath toolbar by using the prefix `default`. To find all the `level` elements when you define a default namespace in the root element, use this expression: `//default:level` in the XPath toolbar.

Working with Archives

11

Topics:

- *Browsing Archives*
- *Working with Archive Files*

Oxygen XML Editor includes a useful ***Archive Browser*** *view* that offers the means to work with files directly from various types of archives (for example, opening and saving files directly in archives, or browsing and modifying archive structures). The archive support is available for all ZIP-type archives, including:

- ZIP archives
- EPUB books
- *JAR archives*
- Office Open XML (OOXML) files
- Open Document Format (ODF) files
- *IDML files*

You can transform, validate, and perform many other operations on files directly from an archive. For instance, you can transform, or validate files directly from OOXML or ODF packages, and the structure and content of the ZIP archives can be opened, edited, and saved, similar to any other ZIP archive browsing tool. Also, when browsing for a URL in various dialog boxes, you can use the  **Browse for archived file** action to browse and select files from a particular archive.

For more information about working with an EPUB archive in Oxygen XML Editor, watch our video demonstration:

Browsing Archives

Oxygen XML Editor includes a helper view called the **Archive Browser** that allows you to view the contents and structure of an archive, and it offers a variety of toolbar and contextual menu actions. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

To open an archive in the **Archive Browser** view, use one of the following methods:

- Open an archive from the ***Project*** *view*.
- Select an archive in one of the file chooser dialog boxes in Oxygen XML Editor (such as the **Open** dialog box).
- Drag an archive from a system file explorer and drop it in the **Archives Browser** view.

When displaying an archive, the **Archive Browser** view locks the archive file. It is then automatically unlocked when the **Archive Browser** view is closed.

Tip: If a file is not recognized by Oxygen XML Editor as a supported archive type, you can add it from the ***Archive*** *preferences page*.

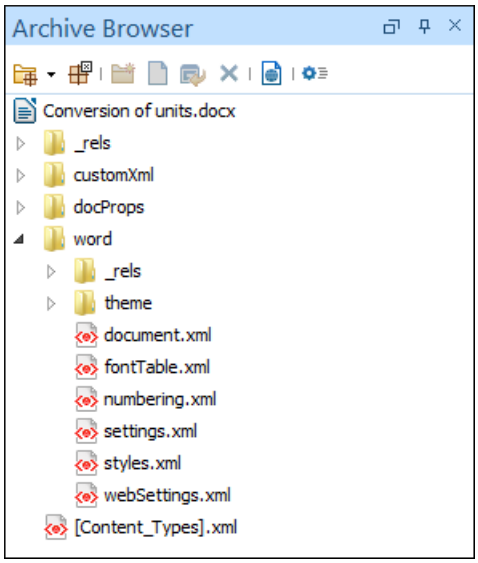

Figure 642: Archive Browser

Archive Browser Toolbar Actions

The following actions are available on the **Archive Browser** toolbar:

Open Archive menu

Provides access to the **Open Archive** action that opens a new archive in the browser. If the extension is not known as an archive extension, you will be directed to the ***Archive*** *preferences page* to add a new extension. The sub-menu keeps a list of recently open archive files and a **Clear history** action that allows you to delete the list.

Close

Closes the browsed archive and unlocks the archive file.

Validate (available for EPUB archives only)

Checks the EPUB archive to see if its content and structure is valid.

New folder

Creates a folder as child of the selected folder in the browsed archive.

New file

Creates a file as child of the selected folder in the browsed archive.

Add files

Adds existing files as children of the selected folder in the browsed archive.

Note: You can also add files in the archive by dragging them from the file browser or the ***Project*** *view* and dropping them in the **Archive Browser** view.

Delete

Deletes the selected resource in the browsed archive.

Open in System Application

Opens the selected resource in the default system application that is associated with that type of file.

Archive Options

Opens the ***Archive*** *preferences page*.

Archive Browser Contextual Menu Actions

The following additional actions are available from the contextual menu for resources in the **Archive Browser** view:

Open

Opens a resource from the archive in the editor.

Extract

Extracts a resource from the archive in a specified folder.

New folder

Creates a folder as child of the selected folder in the browsed archive.

New file

Creates a file as child of the selected folder in the browsed archive.

Add files

Adds existing files as children of the selected folder in the browsed archive.

Note: On OS X, the **Add file** action is also available and it allows you to add one file at a time.

Rename

Renames a resource in the archive.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to search for and replace specific pieces of text inside the archive.

Cut

Cuts the selected archive resource.

Copy

Copies the selected archive resource.

Paste

Pastes a file or folder into the archive.

Delete

Removes a file or folder from archive.

Preview

Previews an image contained in the archive. See the *Image Preview* topic for more details.

Copy location

Copies the URL location of the selected resource.

Refresh

Refreshes the selected resource.

Properties

Shows the properties of the selected resource.

For more information, watch our video demonstration about working with an EPUB in the **Archive Browser** view:

Working with Archive Files

Oxygen XML Editor includes support for working with various types of archives, including the following:

- **EPUB** - An e-book file format that can be used on many types of devices, such as smart phones, tablets, e-readers, or computers.

- **OOXML** - An XML-based file format for representing spreadsheets, charts, presentations, and word processing documents.
- **ODF** - An free and open-source XML-based file format for electronic office documents, such as spreadsheets, charts, presentations, and word processing documents.

When these types of files are opened in the ***Archive Browser*** *view*, their internal components are expanded:

- Document content (XHTML and image files).
- Packaging files.
- Container files.

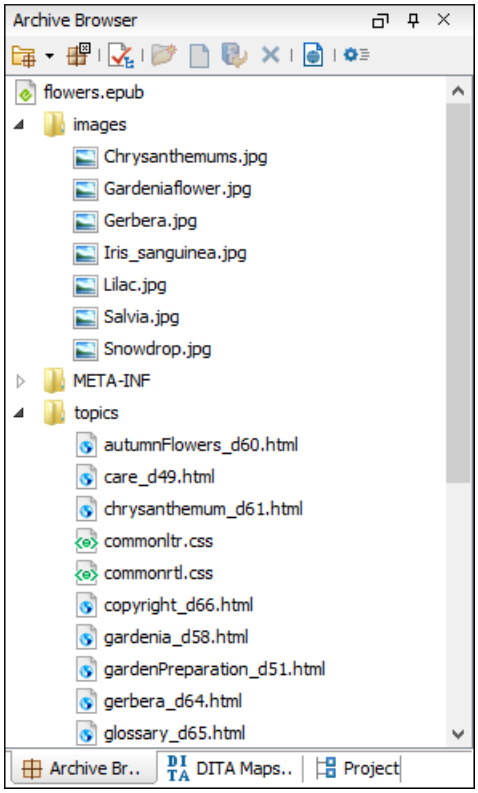

Figure 643: EPUB File Displayed in the Archive Browser View

When an archive is expanded in the ***Archive Browser*** *view*, you can add or delete files that compose the archive structure. All changes made to the structure of an archive are saved immediately. You can open files from within the archive to *edit them in the main editing pane and save changes* back to the archive. You can also use the **Open in System Application** action to open the archive in the default system application that is associated with that type of file.

EPUB-Specific Validation

When working with EPUB archives, the ***Archive Browser*** includes a **Validate** action on the toolbar that checks the EPUB archive to make sure the structure and content are valid. Oxygen XML Editor uses the open-source *EpubCheck* validator to perform the validation. This validator detects many types of errors, including OCF container structure, OPF and OPS mark-up, as well as internal reference consistency.

For more information about working with an EPUB archive in Oxygen XML Editor, watch our video demonstration:

Related Information:

The Archive Browser View on page 1278
EPUB Document Type (Framework) on page 1061

Creating an Archive

To create an archive from scratch, follow these steps:

1. Go to **File** > **New** or click **New** on the main toolbar.
2. Choose your particular type of archive template. For example, select one of the **ODF**, **OOXML**, or **EPUB** templates.
3. Click **Create** and choose the name and location of the file.
4. Click **Save**.
   A skeleton archive is saved on disk and opened in the ***Archive Browser*** *view*.

   Tip: Use toolbar and contextual menu actions to edit, add, and remove resources from the archive. For EPUB archives, you can use the **Validate** action to verify the integrity of the EPUB archive.

Editing and Saving Files Inside an Archive

You can open files directly from an archive in the ***Archive Browser*** *view* and then edit them in the main editor pane. To open a file, simply double-click it or select **Open** from the contextual menu.

When saving the file back to the archive, you are prompted to choose if you want the application to make a backup copy of the archive before saving the new content. If you choose **Never ask me again**, you will not be asked again to make backup copies. You can re-enable the pop-up message from the *Messages preferences page*.

Migrating Archives to DITA or TEI

Certain types of archives can be converted to DITA or TEI. For example, OOXML (Office Open XML) archive files with the DOCX file extension can be migrated to DITA or TEI.

To migrate DOCX files to DITA or TEI, follow these steps:

1. Open and expand the archive in the ***Archive Browser***.
2. Open the **document.xml** file contained in the archive.
3. Run one of the following predefined transformation scenarios:
   a) **DOCX DITA** to migrate to DITA.
   b) **DOCX TEI P5** to migrate to TEI.
4. You may need to do some manual reconfiguring to map DOCX styles to DITA or TEI content.

   Tip: Oxygen XML Editor also includes a predefined transformation scenario called **ODT TEI P5** for converting ODF archive files with the ODT file extension to TEI and a similar process can be used to migrate ODT files to TEI.

Databases and CMS Integration

12

Topics:

- *Working with Databases*
- *Content Management System (CMS) Integration*

Oxygen XML Editor provides support for connecting and integrating with various databases and content management systems. This section includes information about the database-related features in Oxygen XML Editor. It explains how to connect with the supported databases, presents the actions that are available for each type, and includes information about SharePoint and Documentum (CMS) integration.

Working with Databases

XML is a storage and interchange format for structured data and is supported by all major database systems. Oxygen XML Editor offers the means for managing the interaction with some of the most commonly used databases (both *Relational* and *Native XML* databases). Through this interaction, Oxygen XML Editor helps users with browsing, content editing, importing from databases, using XQuery with databases, SQL execution, and generating XML Schema from a database structure.

The types of connections that are supported in Oxygen XML Editor include:

- *IBM DB2*
- *Microsoft SQL Server*
- *Oracle Database*
- *PostgreSQL*
- *Berkeley DB XML*
- *eXist*
- *MarkLogic*
- *Documentum xDB (X-Hive/DB)*
- *MySQL*
- *Generic JDBC*
- *JDBC-ODBC*
- *BaseX*
- *WebDAV*
- *Microsoft SharePoint*

Related Information:

Integration with Microsoft SharePoint on page 1341

Data Source Explorer View

The **Data Source Explorer** view displays your database connections. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

You can connect to a database simply by expanding the connection node (click the connection) . The database structure can be expanded to resource level, or even all the way to column level for tables inside relational databases. Oxygen XML Editor supports multiple simultaneous database connections and the connection tree in the **Data Source Explorer** view provides an easy method for browsing them.

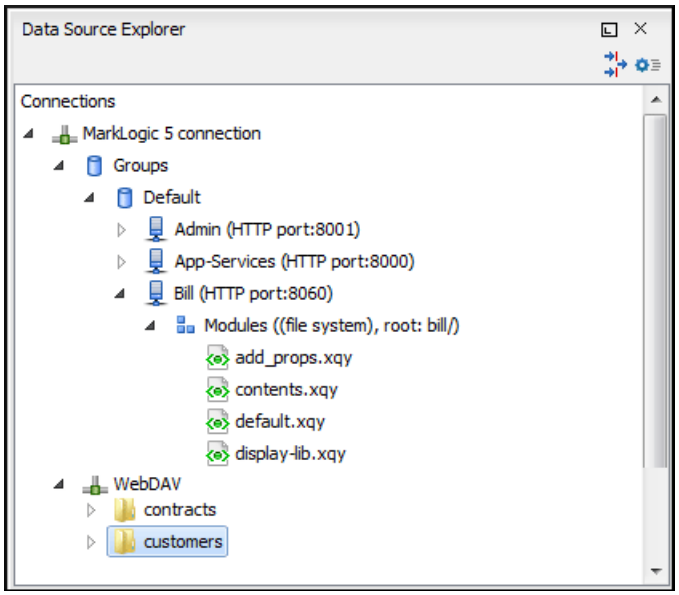

Figure 644: Data Source Explorer View

The objects (nodes) that are displayed in the **Data Source Explorer** view depend on the connection type and structure of the database. Various contextual menu actions are available for each hierarchical level and for some connections you can add or move resources in a container by simply dragging them from the ***Project*** *view*, a file browsing application, or another database.

Toolbar Actions

The following actions are available in the toolbar of this view:

Filters

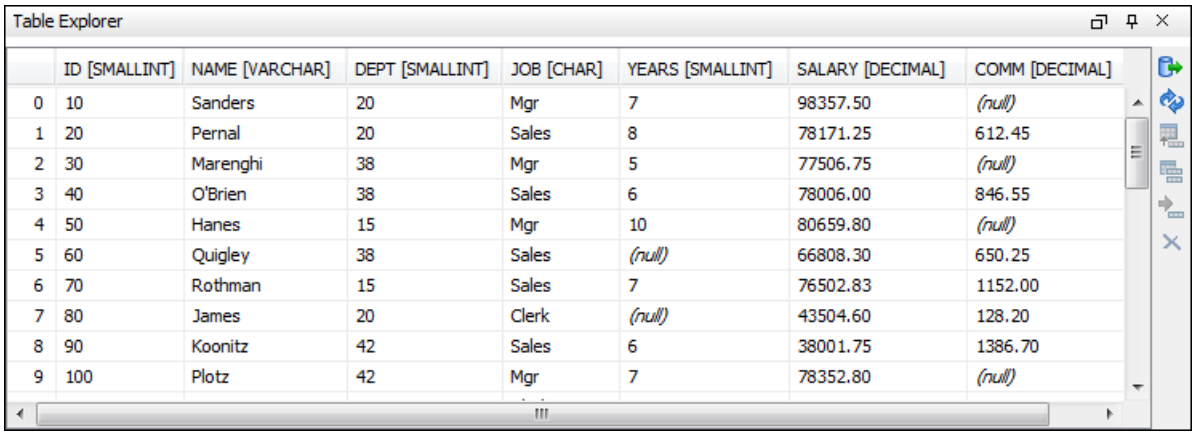
Opens the ***Data Sources / Table Filters*** *preferences page*, allowing you to decide which table types are displayed in the **Data Source Explorer** view.

Configure Database Sources

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Database-Specific Contextual Menu Actions

Each specific type of database will also include its own specific contextual menu actions in the **Data Source Explorer** view. The actions depend on the type of database, the type of node, or the hierarchical level of the node in which the contextual menu is invoked.



For more information on the specific actions that are available, see the topics in this section for each specific type of database.

Related Information:

Data Sources Preferences on page 139

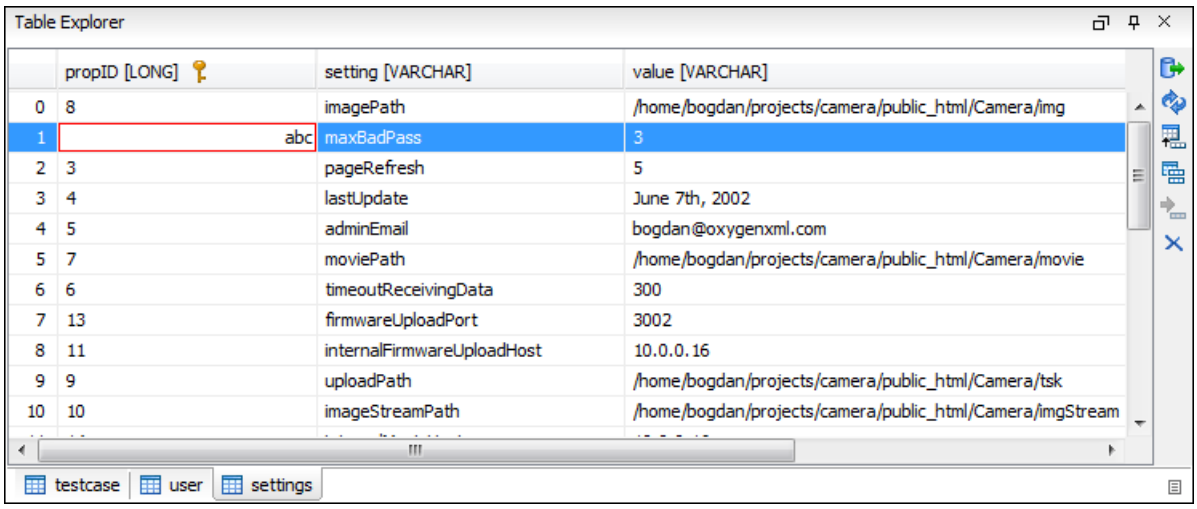
Table Explorer View

Relational databases tables in the ***Data Source Explorer*** *view* can be displayed and edited in the **Table Explorer** view by selecting the **Edit** action from the contextual menu of a **Table** node or by double-clicking one of its fields. To modify the content of a cell, double-click it and start typing. When editing is complete, Oxygen XML Editor attempts to update the database with the new cell content.

	ID [SMALLINT]	NAME [VARCHAR]	DEPT [SMALLINT]	JOB [CHAR]	YEARS [SMALLINT]	SALARY [DECIMAL]	COMM [DECIMAL]
0	10	Sanders	20	Mgr	7	98357.50	*(null)*
1	20	Pernal	20	Sales	8	78171.25	612.45
2	30	Marenghi	38	Mgr	5	77506.75	*(null)*
3	40	O'Brien	38	Sales	6	78006.00	846.55
4	50	Hanes	15	Mgr	10	80659.80	*(null)*
5	60	Quigley	38	Sales	*(null)*	66808.30	650.25
6	70	Rothman	15	Sales	7	76502.83	1152.00
7	80	James	20	Clerk	*(null)*	43504.60	128.20
8	90	Koonitz	42	Sales	6	38001.75	1386.70
9	100	Plotz	42	Mgr	7	78352.80	*(null)*

Figure 645: Table Explorer View

You can sort the content of a table by one of its columns by clicking its column header.



Note the following:

- The first column is an index (not part of the table structure)
- Every column header contains the field name and its data type
- The primary key columns are marked with this symbol:
- Multiple tables are presented in a tabbed manner

For performance issues, you can set the maximum number of cells that are displayed in the **Table Explorer** view (using the ***Limit the number of cells*** *option in the* ***Data Sources*** *Preferences page*). If a table that has more cells than the value set in the options is displayed in the **Table Explorer** view, a warning dialog box informs you that the table is only partially shown.

You are notified if the value you have entered in a cell is not valid (and thus cannot be updated).

- If the content of the edited cell does not belong to the data type of the column, the cell is marked by a red square and remains in an editing state until a correct value is inserted. For example, in the following figure `propID` contains `LONG` values. If a character or string is inserted, the cell will look like this:

	propID [LONG]	setting [VARCHAR]	value [VARCHAR]
0	8	imagePath	/home/bogdan/projects/camera/public_html/Camera/img
1	abc	maxBadPass	3
2	3	pageRefresh	5
3	4	lastUpdate	June 7th, 2002
4	5	adminEmail	bogdan@oxygenxml.com
5	7	moviePath	/home/bogdan/projects/camera/public_html/Camera/movie
6	6	timeoutReceivingData	300
7	13	firmwareUploadPort	3002
8	11	internalFirmwareUploadHost	10.0.0.16
9	9	uploadPath	/home/bogdan/projects/camera/public_html/Camera/tsk
10	10	imageStreamPath	/home/bogdan/projects/camera/public_html/Camera/imgStream

Figure 646: Cell Containing an Invalid Value

- If the constraints of the database are not met (for instance, primary key constraints), an information dialog box will appear, notifying you of the reason the database has not been updated. For example, in the table below, trying to set the second record in the primary key `propID` column to 8, results in a duplicate entry error since that value has already been used in the first record:

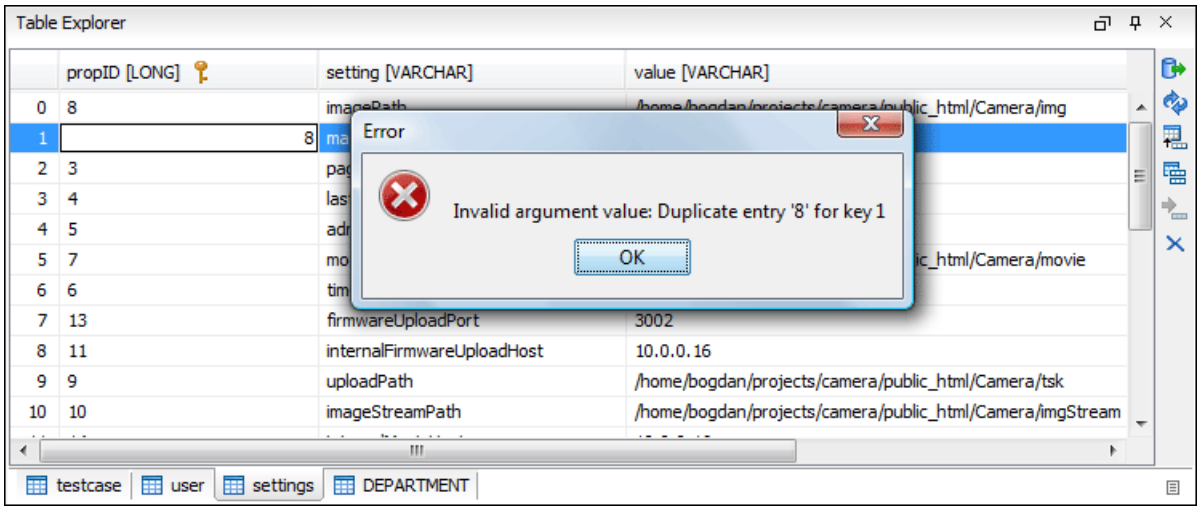


Figure 647: Duplicate Entry for Primary Key

Table Explorer Contextual Menu Actions

Common editing actions (**Cut**, **Copy**, **Paste**, **Select All**, **Undo**, **Redo**) are available in the contextual menu of an edited cell.

The contextual menu, available on every cell in the **Table Explorer** view, also includes the following actions:

Set NULL

Sets the content of the cell to **null**. This action is not available for columns that cannot have a value of **null**.

Insert row

Inserts an empty row in the table.

Duplicate row

Makes a copy of the selected row and adds it in the **Table Explorer** view. Note that the new row will not be inserted in the database table until all conflicts are resolved.

Commit row

Commits the selected row.

Delete row

Deletes the selected row.

Copy

Copies the content of the cell.

Paste

Pastes copied content into the selected cell.

Table Explorer Toolbar Actions

The toolbar of the **Table Explorer** view also includes the following actions:

Export to XML

Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the *Import from database* chapter) .

Refresh

Performs a refresh for the sub-tree of the selected node.

Insert row

Inserts an empty row in the table.

Duplicate row

Makes a copy of the selected row and adds it in the **Table Explorer** view. Note that the new row will not be inserted in the database table until all conflicts are resolved.

Commit row

Commits the selected row.

Delete row

Deletes the selected row.

Database Connection Support

Oxygen XML Editor offers support for a variety of *Relational* and *Native XML* database connections. The database drivers and connections for various types of database are configured in the ***Data Sources*** *preferences page* and once configured, the database connections can be viewed and managed in the ***Data Source Explorer*** *view*. Oxygen XML Editor also includes a ***Database*** *perspective* that helps you to manage databases.

The database support in Oxygen XML Editor offers a variety of capabilities, including:

- Browsing the structure of databases in the ***Data Source Explorer*** *view*.
- Viewing relational tables in the ***Table Explorer*** *view*.
- Executing SQL queries against databases.
- Calling stored procedures with input and output parameters.
- XQuery execution with databases.
- Exporting data from databases to XML.

Relational Database Support

Relational databases use a relational model and are based on tables linked by a common key. Oxygen XML Editor offers support for the most commonly used relational databases, including:

- IBM DB2
- Oracle 11g
- Microsoft SQL Server
- PostgreSQL
- MySQL

Oxygen XML Editor also offers generic support (table browsing and execution of SQL queries) for any JDBC-compliant database (for example, *MariaDB*).

Native XML Database Support

Native XML databases have an XML-based internal model and their fundamental unit of storage is XML. They use XML as an interface to specify documents as tree structured data that may contain unstructured text, but on disk the data is stored as optimized binary files. This makes query and retrieval processes faster. Oxygen XML Editor offers support for the most commonly used native XML databases, including:

- Berkeley DB XML
- eXist
- MarkLogic
- Documentum xDB (X-Hive/DB) 10
- Oracle XML DB
- Base X

WebDAV Connections on page 1326
Integration with Microsoft SharePoint on page 1341

IBM DB2 Database Connections

Oxygen XML Editor includes support for IBM DB2 database connections. Oxygen XML Editor allows you to browse the structure of an IBM DB2 database in the ***Data Source Explorer** view*, open tables in the ***Table Explorer** view*, and perform various operations on the resources in the repository.

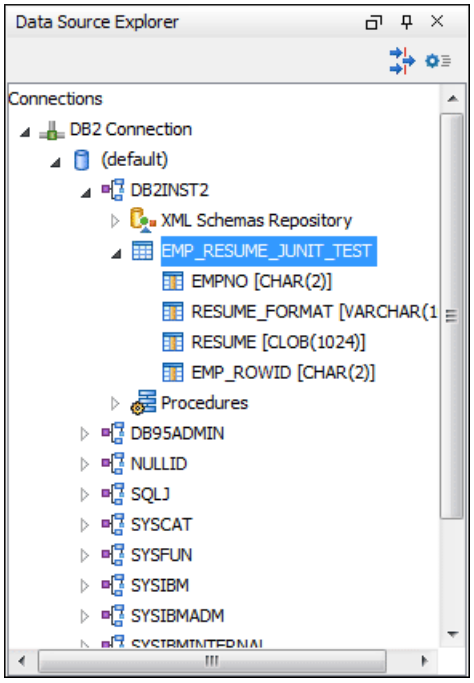

Figure 648: IBM DB2 Database Connection

Configuring an IBM DB2 Database Connection

To configure the support for the IBM DB2 database, follow this procedure:

1. Go to the *IBM website* and in the *DB2 Clients and Development Tools* category select the *DB2 Driver for JDBC and SQLJ* download link. Fill out the download form and download the zip file. Unzip the zip file and use the `db2jcc.jar` and `db2jcc_license_cu.jar` files in Oxygen XML Editor for *configuring a DB2 data source*.
2. *Configure IBM DB2 Data Source drivers*.
3. *Configure an IBM DB2 Server Connection*.
4. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure IBM DB2 Data Source Drivers

Available in the Enterprise edition only.

To configure a data source for connecting to an IBM DB2 server, follow these steps:

1. Go to the *IBM website* and in the *DB2 Clients and Development Tools* category select the *DB2 Driver for JDBC and SQLJ* download link. Fill out the download form and download the zip file.
2. Unzip the downloaded archive.
3. *Open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **Data Sources**.
4. Click the **New** button in the **Data Sources** panel.

   The dialog box for configuring a data source is opened.

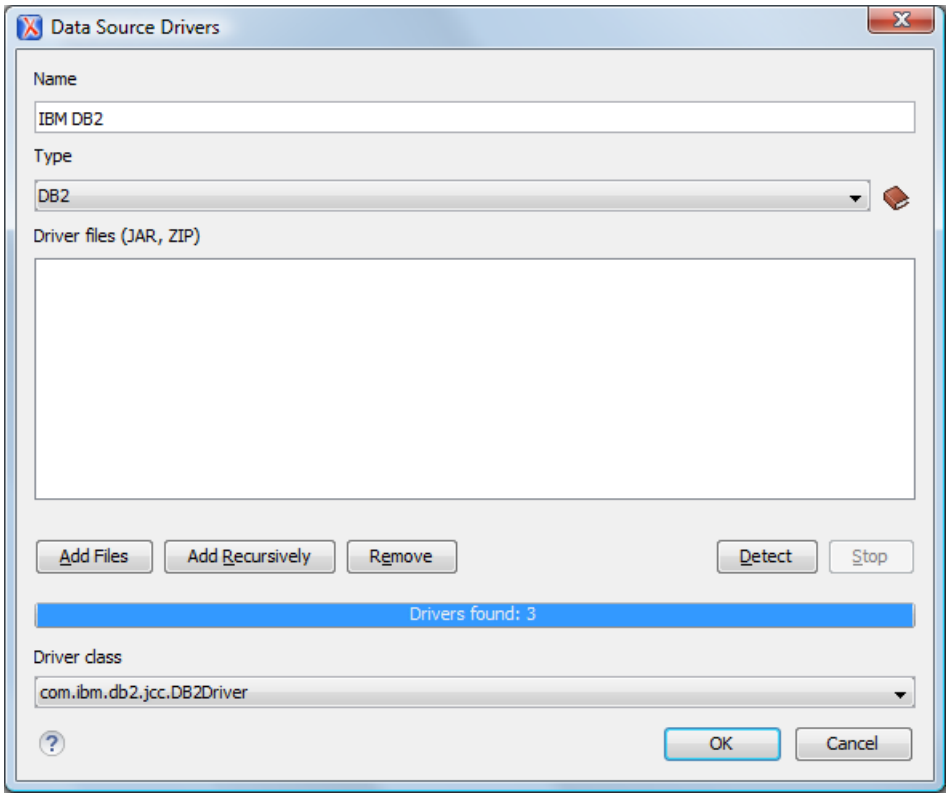

Figure 649: Data Source Drivers Configuration Dialog Box

5. Enter a unique name for the data source.
6. Select *DB2* in the driver **Type** drop-down menu.
7. Click the **Add Files** button and select the IBM DB2 driver files from the archive that you downloaded and unzipped.

   The IBM DB2 driver files are:

   - `db2jcc.jar`
   - `db2jcc_license_cisuz.jar`
   - `db2jcc_license_cu.jar`
8. Select the most appropriate **Driver class**.
9. Click the **OK** button to finish the data source configuration.
10. Continue on to *configure your IBM DB2 connection*.

How to Configure an IBM DB2 Connection

The support to create an IBM DB2 connection is available in the Enterprise edition only.

To configure a connection to an IBM DB2 server, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the + **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

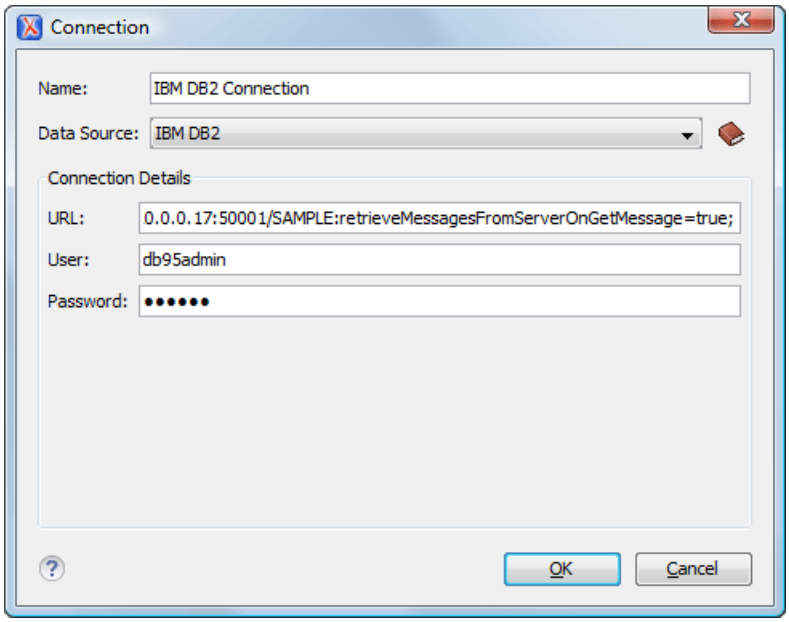

Figure 650: Connection Configuration Dialog Box

3. Enter a unique name for the connection.
4. Select an *IBM DB2* data source in the **Data Source** drop-down menu.
5. Enter the connection details.
   a) Enter the URL to the installed IBM DB2 engine.
   b) Enter the user name to access the IBM DB2 engine.
   c) Enter the password to access the IBM DB2 engine.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

IBM DB2 Contextual Menu Actions

General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the ***Data Source Explorer*** *view*, depending on the node in which it is invoked:

Refresh

Performs a refresh on the selected node.

Disconnect (available on Connection nodes)

Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

Configure Database Sources (available on Connection nodes)

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Edit (available on Table nodes)

Opens the selected table in the ***Table Explorer*** *view*.

Export to XML (available on Table nodes)

Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the *Import from Database* chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the ***Data Source Explorer*** *view*, the various nodes in IBM DB2 connections include the following additional contextual menu actions:

XML Schema Repository Level Nodes

Register

Opens a dialog box for adding a new schema file in the DB XML repository. In this dialog box, you enter a collection name and the necessary schema files. Schema dependencies management can be done by using the **Add** and **Remove** buttons.

Schema Level Nodes

Unregister

Removes the selected schema from the XML Schema Repository.

View

Opens the selected schema in Oxygen XML Editor.

Microsoft SQL Server Database Connections

Oxygen XML Editor includes support for Microsoft SQL Server database connections. Oxygen XML Editor allows you to browse the structure of a SQL Server database in the ***Data Source Explorer*** *view*, open tables in the ***Table Explorer*** *view*, and perform various operations on the resources in the repository.

Configuring a Microsoft SQL Server Connection

To configure the support for a Microsoft SQL Server database, follow this procedure:

1. Download the appropriate MS SQL JDBC driver from the Microsoft website. For SQL Server 2008 R2 and older go to *http://www.microsoft.com/en-us/download/details.aspx?id=21599*. For SQL Server 2012 and 2014 go to *http://www.microsoft.com/en-us/download/details.aspx?id=11774*.
2. *Configure MS SQL Server Data Source drivers*.
3. *Configure a MS SQL Server Connection*.
4. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure Microsoft SQL Server Data Source Drivers

Available in the Enterprise edition only.

To configure a data source for connecting to a Microsoft SQL server, follow these steps:

1. Download the appropriate MS SQL JDBC driver from the Microsoft website. For SQL Server 2008 R2 and older, go to *http://www.microsoft.com/en-us/download/details.aspx?id=21599*. For SQL Server 2012 and 2014, go to *http://www.microsoft.com/en-us/download/details.aspx?id=11774*.
2. *Open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.

   The dialog box for configuring a data source is opened.

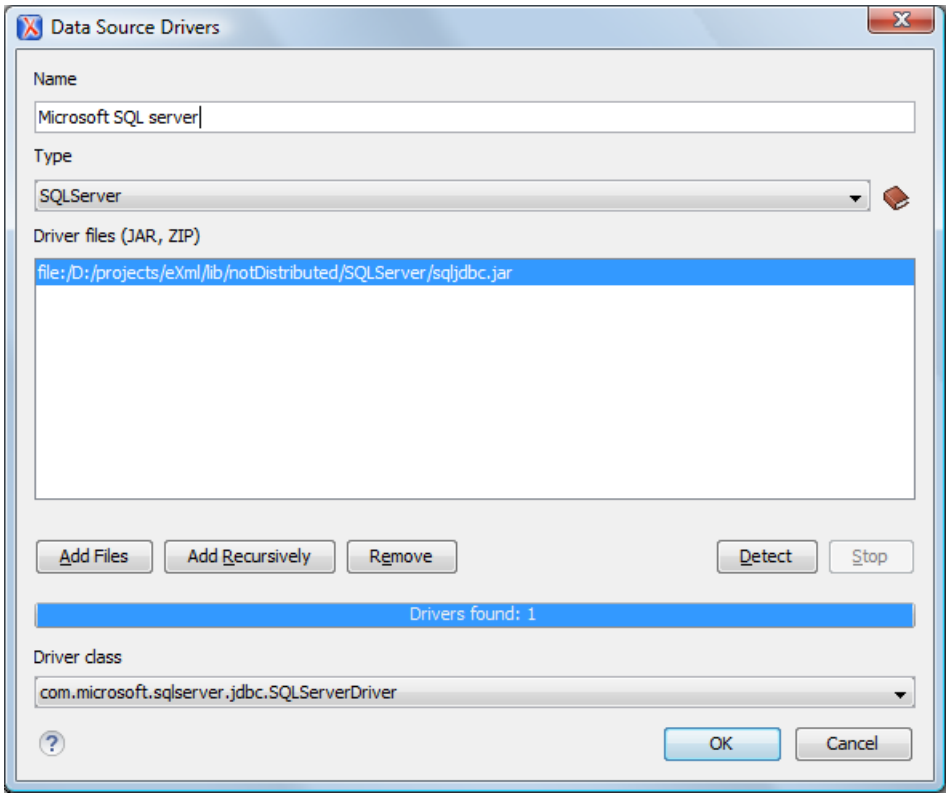

Figure 651: Data Source Drivers Configuration Dialog Box

4. Enter a unique name for the data source.
5. Select *SQLServer* in the driver **Type** drop-down menu.
6. Click the **Add Files** button and select the Microsoft SQL Server driver file that you downloaded.
   The SQL Server driver file is called `sqljdbc.jar`.
7. Select the most appropriate **Driver class**.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to *configure your Microsoft SQL Server connection*.

How to Configure a Microsoft SQL Server Connection

The support to configure a Microsoft SQL Server connection is available in the Enterprise edition only.

To configure a connection to a Microsoft SQL Server, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **+** **New** button in the **Connections** panel.
   The dialog box for configuring a database connection is displayed.

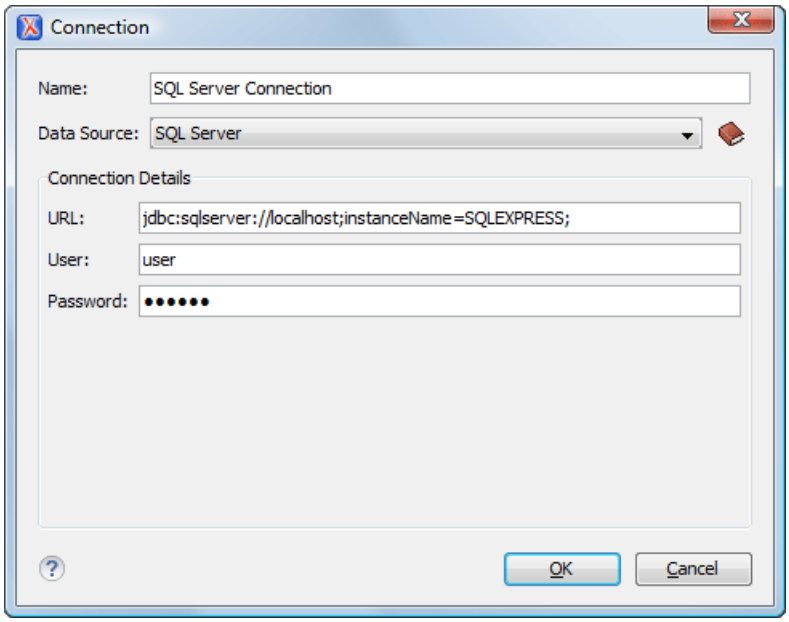

Figure 652: Connection Configuration Dialog Box

3. Enter a unique name for the connection.
4. Select the *SQL Server* data source in the **Data Source** drop-down menu.
5. Enter the connection details.
   a) Enter the URL of the SQL Server server.

      If you want to connect to the server using Windows integrated authentication, you must add `;integratedSecurity=true` to the end of the URL. The URL will look like this:

      ```
      jdbc:sqlserver://localhost;instanceName=SQLEXPRESS;integratedSecurity=true;
      ```

      Note: For integrated authentication, leave the **User** and **Password** fields empty.
   b) Enter the user name for the connection to the SQL Server.
   c) Enter the password for the connection to the SQL Server.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

Microsoft SQL Server Contextual Menu Actions

General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the ***Data Source Explorer*** *view*, depending on the node in which it is invoked:

Refresh

Performs a refresh on the selected node.

Disconnect (available on Connection nodes)

Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

Configure Database Sources (available on Connection nodes)

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Edit (available on Table nodes)

Opens the selected table in the ***Table Explorer*** *view*.

Export to XML (available on Table nodes)

Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the *Import from Database* chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the ***Data Source Explorer** view*, the resource level nodes in Microsoft SQL Server connections include the following additional contextual menu action:

XML Schema Repository Level Nodes

Register

Opens a dialog box for adding a new schema file in the DB XML repository. In this dialog box, you enter a collection name and the necessary schema files. Schema dependencies management can be done by using the **Add** and **Remove** buttons.

Schema Level Nodes

Add

Adds a new schema to the XML Schema files.

Unregister

Removes the selected schema from the XML Schema Repository.

View

Opens the selected schema in Oxygen XML Editor.

Oracle Database Connections

The Oracle database is a common relational type of database system. Oxygen XML Editor comes with built-in support for the 11g version of the database system. The Oracle database also includes a Oracle XML DB component that adds native XML support. Oxygen XML Editor allows you to browse Oracle repositories in the ***Data Source Explorer** view*, open tables in the ***Table Explorer** view*, and perform various operations on the resources in the repository.

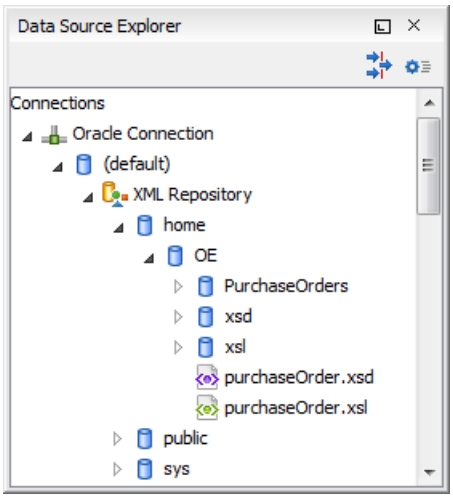

Figure 653: Oracle Database Connection

Related Information:
Using XQuery with Oracle XML DB

Configuring an Oracle 11g Database Connection

To configure the support for a Oracle 11g database, follow this procedure:

1. Go to *http://www.oracle.com/technetwork/database/enterprise-edition/jdbc-112010-090769.html* and download the Oracle 11g JDBC driver called `ojdbc6.jar`.

2. *Configure Oracle 11g Data Source drivers*.
3. *Configure an Oracle 11g Connection*.
4. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure Oracle 11g Data Source Drivers

Available in the Enterprise edition only.

To configure a data source for connecting to an Oracle 11g server, follow these steps:

1. Go to *http://www.oracle.com/technetwork/database/enterprise-edition/jdbc-112010-090769.html* and download the Oracle 11g JDBC driver called `ojdbc6.jar`.
2. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.

   The dialog box for configuring a data source is opened.

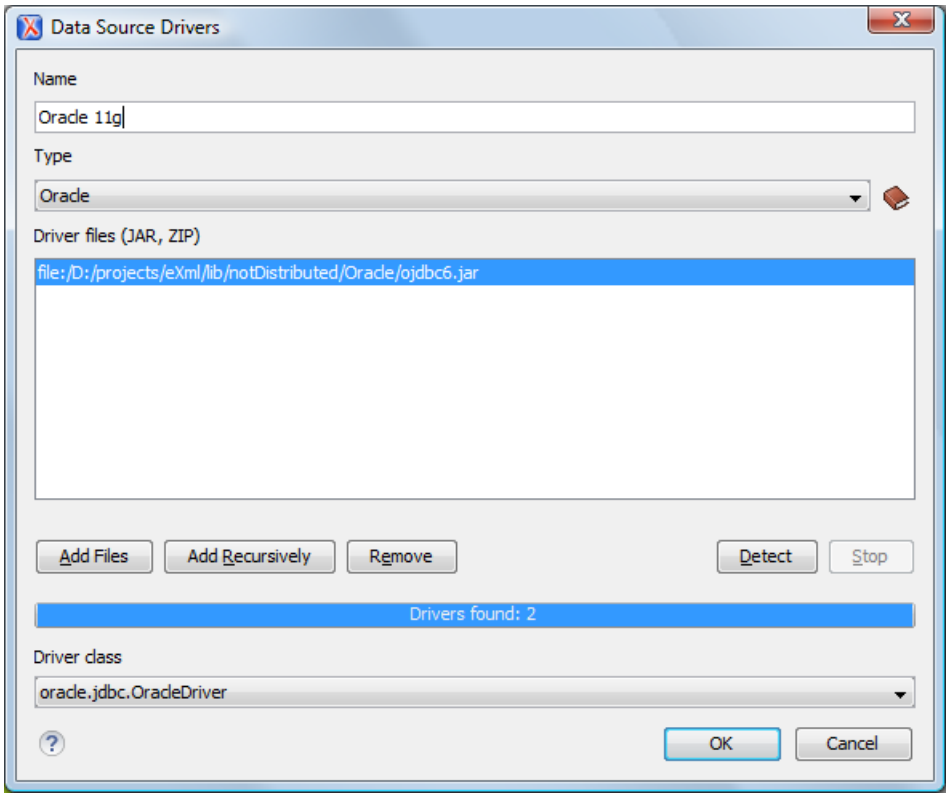

Figure 654: Data Source Drivers Configuration Dialog Box

4. Enter a unique name for the data source.
5. Select *Oracle* in the driver **Type** drop-down menu.
6. Click the **Add Files** button and select the Oracle driver file that you downloaded.

   The Oracle driver file is called `ojdbc5.jar`.
7. Select the most appropriate **Driver class**.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to *configure your Oracle connection*.

How to Configure an Oracle 11g Connection

Available in the Enterprise edition only.

To configure a connection to an Oracle 11g server, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.

2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

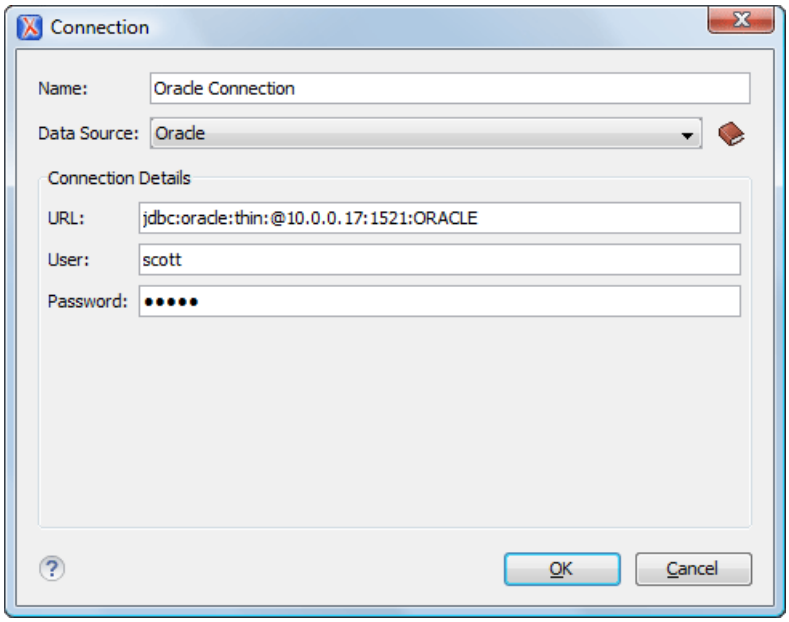

Figure 655: Connection Configuration Dialog Box

3. Enter a unique name for the connection.
4. Select the *Oracle 11g* data source in the **Data Source** drop-down menu.
5. Enter the connection details.
   a) Enter the URL of the Oracle server.
   b) Enter the user name for the connection to the Oracle server.
   c) Enter the password for the connection to the Oracle server.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

Oracle Database Contextual Menu Actions

General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the ***Data Source Explorer*** *view*, depending on the node in which it is invoked:

Refresh

Performs a refresh on the selected node.

Disconnect (available on Connection nodes)

Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

Configure Database Sources (available on Connection nodes)

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Edit (available on Table nodes)

Opens the selected table in the ***Table Explorer*** *view*.

Export to XML (available on Table nodes)

Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the *Import from Database* chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the ***Data Source Explorer*** *view*, the various nodes in Oracle database connections include the following additional contextual menu actions:

XML Schema Repository Level Nodes

Register

Opens a dialog box for adding a new schema file in the XML repository. To add an XML Schema, enter the schema URI and location on your file system. *Local* scope means that the schema is visible only to the user who registers it. *Global* scope means that the schema is public.

Note: Registering a schema may involve dropping/creating types. Hence you need type-related privileges such as DROP TYPE, CREATE TYPE, and ALTER TYPE. You need privileges to delete and register the XML schemas involved in the registering process. You need all privileges on XMLType tables that conform to the registered schemas. For XMLType columns, the ALTER TABLE privilege is needed on corresponding tables. If there are schema-based XMLType tables or columns in other database schemas, you need privileges such as the following:

- `CREATE ANY TABLE`
- `CREATE ANY INDEX`
- `SELECT ANY TABLE`
- `UPDATE ANY TABLE`
- `INSERT ANY TABLE`
- `DELETE ANY TABLE`
- `DROP ANY TABLE`
- `ALTER ANY TABLE`
- `DROP ANY INDEX`

To avoid having to grant all these privileges to the schema owner, Oracle recommends that the registration be performed by a DBA if there are XML schema-based XMLType table or columns in other user database schemas.

XML Repository Level Nodes

Add container

Adds a new child container to the current one.

Add resource

Adds a new resource to the folder.

Container Level Nodes

Add container

Adds a new child container to the current one.

Add resource

Adds a new resource to the folder.

Delete

Deletes the current container.

Properties

Shows various properties of the current container.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application

associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Rename

Renames the current resource

Move

Moves the current resource to a new container (also available through drag and drop).

Delete

Deletes the current container.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Properties

Shows various properties of the current container.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

PostgreSQL Database Connections

Oxygen XML Editor includes support for PostgreSQL database connections. Oxygen XML Editor allows you to browse the structure of a PostgreSQL database in the ***Data Source Explorer*** *view*, open tables in the ***Table Explorer*** *view*, and perform various operations on the resources in the repository.

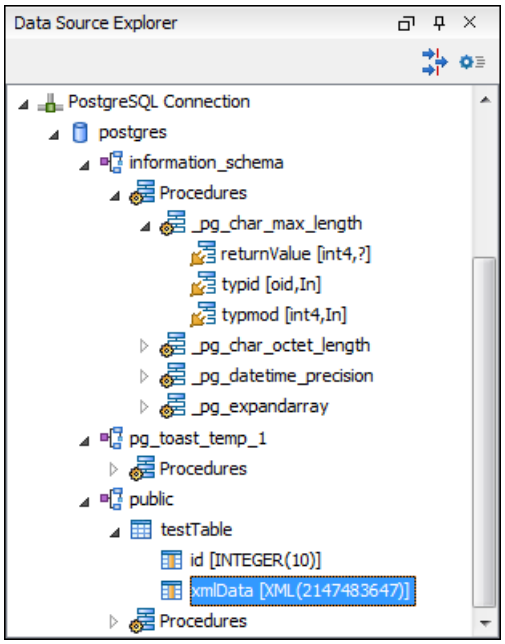

Figure 656: PostgreSQL Database Connection

Configuring a PostgreSQL Database Connection

To configure the support for a PostgreSQL database, follow this procedure:

1. Go to *http://jdbc.postgresql.org/download.html* and download the PostgreSQL 8.3 JDBC3 driver.
2. *Configure PostgreSQL Data Source drivers*.
3. *Configure a PostgreSQL Connection*.
4. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure PostgreSQL 8.3 Data Source Drivers

To configure a data source for connecting to a PostgreSQL server, follow these steps:

1. Go to *http://jdbc.postgresql.org/download.html* and download the PostgreSQL 8.3 JDBC3 driver.
2. *Open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Data Sources**.
3. Click the + **New** button in the **Data Sources** panel.

   The dialog box for configuring a data source is opened.
4. Enter a unique name for the data source.
5. Select *PostgreSQL* in the driver **Type** drop-down list.
6. Click the **Add Files** button and select the PostgreSQL driver file that you downloaded.
   The PostgreSQL driver file is called `postgresql-8.3-603.jdbc3.jar`.
7. Select the most appropriate **Driver class**.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to *configure your PostgreSQL connection*.

How to Configure a PostgreSQL 8.3 Connection

To configure a connection to a PostgreSQL 8.3 server, follow these steps:

1. *Open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Data Sources**.
2. Click the + **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

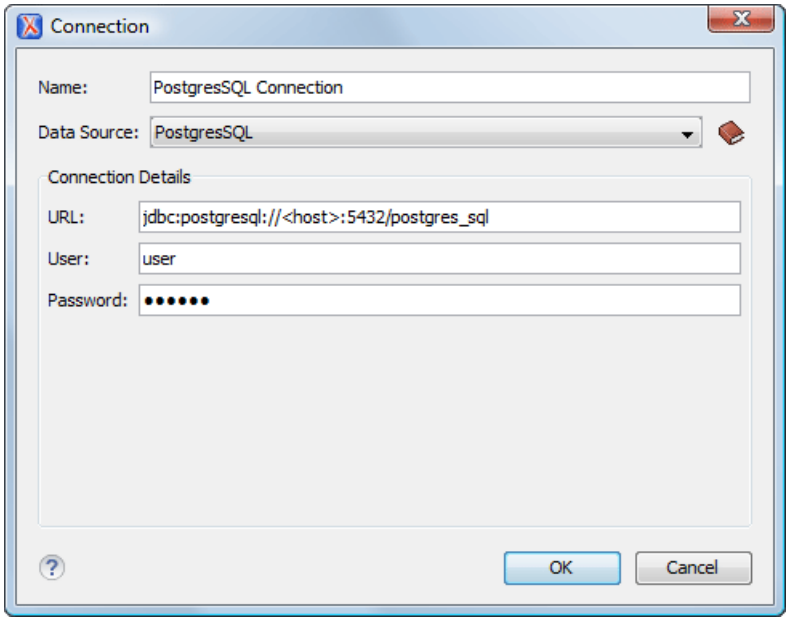

Figure 657: Connection Configuration Dialog Box

3. Enter a unique name for the connection.
4. Select the *PostgreSQL 8.3* data source in the **Data Source** drop-down menu.
5. Enter the connection details.
   a) Enter the URL of the PostgreSQL 8.3 server.
   b) Enter the user name for the connection to the PostgreSQL 8.3 server.
   c) Enter the password for the connection to the PostgreSQL 8.3 server.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

PostgreSQL Contextual Menu Actions

General Contextual Menu Actions

For relational databases, the following general actions are available in the contextual menu of the ***Data Source Explorer*** *view*, depending on the node in which it is invoked:

Refresh

Performs a refresh on the selected node.

Disconnect (available on Connection nodes)

Closes the current database connection. If a table is already open, you are warned to close it before proceeding.

Configure Database Sources (available on Connection nodes)

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Edit (available on Table nodes)

Opens the selected table in the ***Table Explorer*** *view*.

Export to XML (available on Table nodes)

Opens the **Export Criteria** dialog box (a thorough description of this dialog box can be found in the *Import from Database* chapter).

Database-Specific Contextual Menu Actions

In addition to the general contextual menu actions in the ***Data Source Explorer*** *view*, the resource level nodes in PostgreSQL connections include the following additional contextual menu action:

Resource Level Nodes

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

Berkeley DB XML Database Connections

Oxygen XML Editor includes support for Berkeley DB XML database connections. Oxygen XML Editor allows you to browse the structure of a Berkeley DB XML database in the ***Data Source Explorer*** *view* and perform various operations on the resources in the repository.

Oracle Berkeley DB XML is an open source, embeddable XML database with XQuery-based access to documents stored in containers and indexed based on their content. It is built on top of the Oracle Berkeley DB and inherits its features and attributes, along with native XML support. A detailed description can be found at: *http://www.oracle.com/us/products/database/berkeley-db/xml/overview/index.html*.

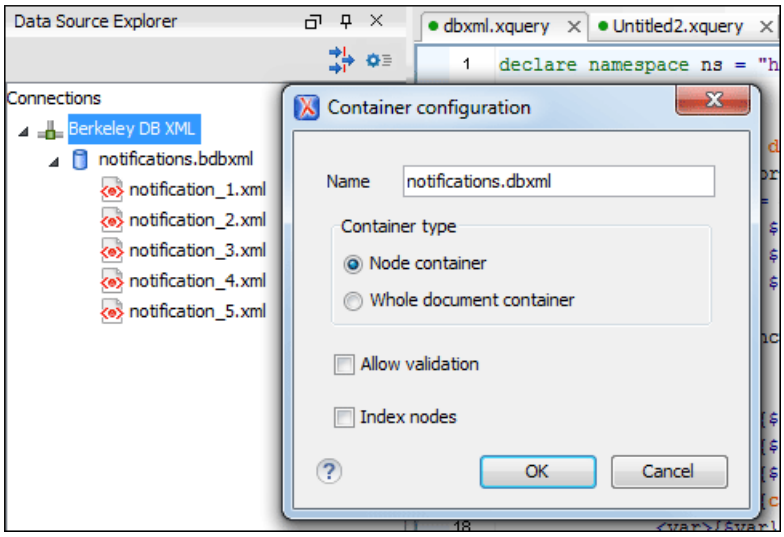

Figure 658: Berkeley DB XML Connection

Configuring a Berkeley DB XML Database Connection

Follow this procedure to configure the support for a Berkeley DB XML database:

1. *Configure Berkeley DB XML Data Source drivers*.
2. *Configure a Berkeley DB XML Connection*.
3. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure Berkeley DB XML Data Source Drivers

For this procedure, you need to already have a Berkeley DB XML database installed on your system.

Oxygen XML Editor supports Berkeley DB XML versions 2.3.10, 2.4.13, 2.4.16 & 2.5.16. To configure a data source for a Berkeley DB XML database, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Data Sources** panel.
3. Enter a unique name for the data source.
4. Select *Berkeley DBXML* from the driver **Type** drop-down menu.
5. Click the **Add Files** button to add the Berkeley DB driver files.

   The driver files for the Berkeley DB database (and their locations) are as follows:

   - `db.jar` (check for it in `[DBXML_DIR]/lib` or `[DBXML_DIR]/jar`)
   - `dbxml.jar` (check for it in `[DBXML_DIR]/lib` or `[DBXML_DIR]/jar`)

   Where `[DBXML_DIR]` is the Berkeley DB XML database root directory. For example, in Windows it is: `C:\Program Files\Oracle\Berkeley DB XML <version>`.
6. Click the **OK** button to finish the data source configuration.
7. Continue on to *configure your Berkeley DB XML connection*.

How to Configure a Berkeley DB XML Connection

Oxygen XML Editor supports Berkeley DB XML versions 2.3.10, 2.4.13, 2.4.16 & 2.5.16. To configure a connection to a Berkeley DB XML database, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select a previously configured Berkeley data source from the **Data Source** drop-down menu.
5. Enter the connection details.

a) Set the path to the Berkeley DB XML `database` directory in the **Environment home directory field**. Use a directory with write access. DO NOT use the installation directory where Berkeley DB XML is installed if you do not have write access to that directory.
b) Select the **Verbosity** level: *DEBUG*, *INFO*, *WARNING*, or *ERROR*.
c) Optionally, you can select the **Join existing environment** checkbox.

   If selected, an attempt is made to join an existing environment in the specified home directory and all the original environment settings are preserved. If that fails, try reconfiguring the connection with this option unchecked.

6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

Berkeley DB XML Contextual Menu Actions

While browsing Berkeley DB XML connections in the ***Data Source Explorer*** *view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

New Collection

Opens a **Container configuration** dialog box that allows you to adds a new container in the repository.

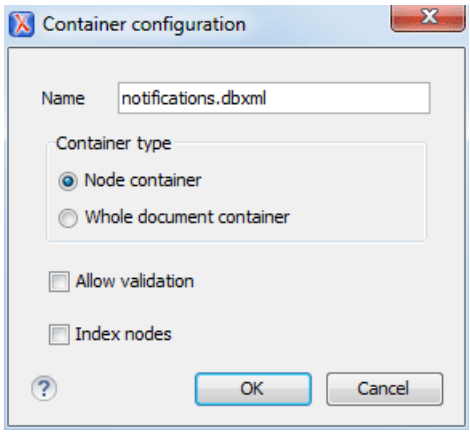

Figure 659: Container Configuration Dialog Box

This dialog box allows you to configure the following:

- **Name** - The name of the new container.
- **Container type** - At creation time, every container must have a type defined for it. This container type identifies how XML documents are stored in the container. As such, the container type can only be determined at container creation time. You cannot change it when subsequent container opens. You can select one of the following types:
  - **Node container** - XML documents are stored as individual nodes in the container. Each record in the underlying database contains a single leaf node, its attributes and attribute values (if any), and its text nodes (if any). Berkeley DB XML also keeps the information it requires to reassemble the document from the individual nodes stored in the underlying databases. This is the default selection and is the preferred container type.
  - **Whole document container** - The container contains entire documents. The documents are stored without any manipulation of line breaks or whitespace.
- **Allow validation** - If selected, documents will be validated when they are loaded into the container. The default behavior is to not validate documents.

- **Index nodes** - If selected, indices for the container will return nodes rather than documents. The default is to index at the document level. This property has no meaning if the container type is **Whole document container**.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Container Level Nodes

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource

Delete

Deletes the current container.

Edit indices

Opens a **Container Indices** dialog box that allows you to configure indices properties for the selected Berkeley container.

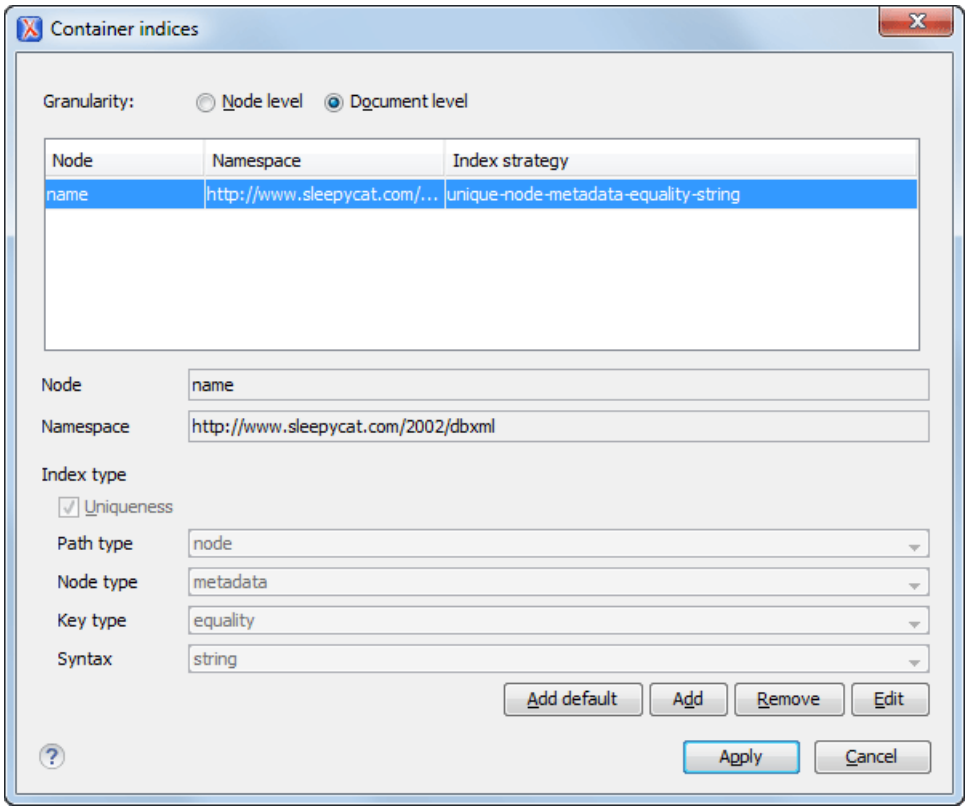

Figure 660: Container Indices Dialog Box

This dialog box allows you to configure the following properties:

- **Granularity** - A measure of the level of details of your data in the database. You can select one of the following:
  - **Document level** - Good option for retrieving large documents.
  - **Node level** - Good option for retrieving nodes from within documents.
- **Node** - The name of the node.
- **Namespace** - The index namespace.
- **Index type**:
  - **Uniqueness** - Indicates whether or not the indexed value must be unique within the container.
  - **Path type** - Drop-down menu that allows you to select from the following:
    - **node** - Indicates that you want to index a single node in the path.
    - **edge** - Indicates that you want to index the portion of the path where two nodes meet.
  - **Node type** - Drop-down menu that allows you to select from the following:
    - **element** - An element node in the document content.
    - **attribute** - An attribute node in the document content.
    - **metadata** - A node found only in the metadata content of a document.
  - **Key type** - Drop-down menu that allows you to select from the following:
    - **equality** - Improves the performances of tests that look for nodes with a specific value.
    - **presence** - Improves the performances of tests that look for the existence of a node regardless of its value.
    - **substring** - Improves the performance of tests that look for a node whose value contains a given sub-string.
  - **Syntax** - The syntax describes the type of data the index contains and is mostly used to determine how indexed values are compared. The default value is `string`.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Cut

Removes the current selection and places it in the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

Debugging with Berkeley DB XML

The Berkeley DB XML database added a debugging interface starting with version 2.5. The current version is supported in the Oxygen XML Editor XQuery Debugger. *The same restrictions and peculiarities* apply for the Berkeley debugger as for the MarkLogic debugger.

eXist Database Connections

Oxygen XML Editor includes support for eXist database connections. Oxygen XML Editor allows you to browse the structure of a eXist database in the ***Data Source Explorer*** *view* and perform various operations on the resources in the repository.

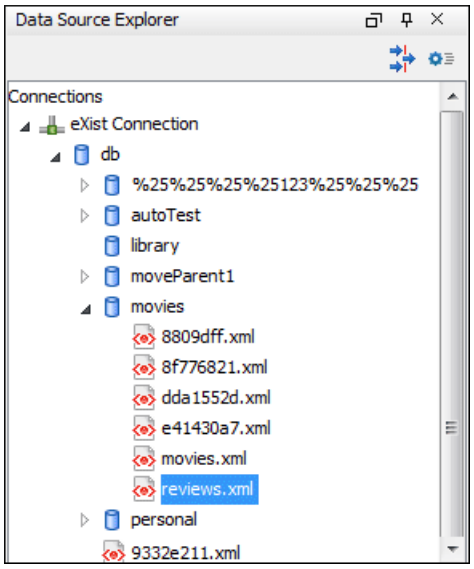

Figure 661: eXist Database Connection

Configuring an eXist Database Connection

There are two ways to configure the support for an eXist database:

- Use the dedicated **Create eXist-db XML connection** wizard.
  1. *Open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Data Sources** and click the **Create eXist-db XML connection** link.
  2. Enter your connection details in the connection wizard and click **OK**.

     Important: To create an eXist connection using this wizard, Oxygen XML Editor expects the `exist/webstart/exist.jnlp` path to be accessible at the provided **Host** and **Port**.
  3. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.
- Use the **Data Sources** preferences page to configure your connection.
  1. *Configure eXist Data Source drivers*.
  2. *Configure an eXist Connection*.
  3. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure eXist Data Source Drivers

For this procedure, you need to already have an eXist database server installed.

Oxygen XML Editor supports eXist database server versions up to and including version 3.0. To configure a data source for an eXist database, follow these steps:

1. *Open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Data Sources**.
2. Click the **New** button in the **Data Sources** panel.
3. Enter a unique name for the data source.
4. Select *eXist* from the driver **Type** drop-down menu.
5. Click the **Add Files** button to add the eXist driver files.

   The following driver files should be added and they are found in the installation directory of the eXist database server. Make sure you copy the files from the installation of the eXist server where you want to connect from Oxygen XML Editor.

   - `exist.jar`
   - `lib/core/xmldb.jar`
   - `lib/core/xmlrpc-client-3.1.x.jar`
   - `lib/core/xmlrpc-common-3.1.x.jar`

- `lib/core/ws-commons-util-1.0.x.jar`
- `lib/core/slf4j-api-1.x.x.jar` (if available)
- `lib/core/slf4j-log4j12-1.x.x.jar` (if available)

The version number from the driver file names may be different for your eXist server installation.

6. Click the **OK** button to finish the data source configuration.
7. Continue on to *configure your eXist connection*.

For more information about running XQuery against an eXist XML database, watch our video demonstration:

How to Configure an eXist Connection

To configure a connection to an eXist database, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select a previously configured eXist data source from the **Data Source** drop-down menu.
5. Enter the connection details.
   a) Set the URI to the installed eXist engine in the **XML DB URI** field.
   b) Set the user name in the **User** field.
   c) Set the password in the **Password** field.
   d) Enter the start collection in the **Collection** field.

   eXist organizes all documents in hierarchical collections. Collections are like directories. They are used to group related documents together. This text field allows the user to set the default collection name.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

   For more information about running XQuery against an eXist XML database, watch our video demonstration:

eXist Contextual Menu Actions

While browsing eXist database connections in the ***Data Source Explorer** view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources** preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files** dialog box* that allows you to find and replace text in multiple files from the connection.

Container Level Nodes

New File

Creates a new file on the connection, in the current folder.

New Collection

Creates a new collection on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Paste

Pastes the copied selection.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Save As

Allows you to save the selected resource as a file on disk.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

MarkLogic Database Connections

Oxygen XML Editor Enterprise edition includes support for MarkLogic database connections. Once you *configure a MarkLogic connection*, you can use the ***Data Source Explorer*** *view* to display all the application servers that are configured on the MarkLogic server. You can expand each application server and view all of its configured modules, and the ***Data Source Explorer*** *view* allows you to open and edit these modules.

Note: To browse modules located in a database, directory properties must be associated with them. These directory properties are generated automatically if the *directory creation* property of the database is set to automatic. If this property is set to **manual** or **manual-enforced**, add the directory properties of the modules manually, using the XQuery function `xdmp:directory-create()`. For example, for two documents with the `/code/modules/main.xqy` and `/code/modules/imports/import.xqy` IDs, run the following query:

```
(xdmp:directory-create('/code/modules/'), xdmp:directory-create('/code/modules/
imports/'))
```

For more information about directory properties, go to: *http://blakeley.com/blogofile/2012/03/19/directory-assistance/*.

MarkLogic and XQuery

MarkLogic connections can be used in conjunction with XQuery scripts to debug and solve problems with XQuery transformations. XQuery modules can also be validated using a MarkLogic server to allow to you to spot possible issues without the need of actually executing the XQuery script.

When *debugging XQuery files with MarkLogic*, you can use the ***Data Source Explorer*** *view* to open the files from the application server that is involved in the debugging process. By using the ***Data Source Explorer*** *view*, any imported modules are better identified by the MarkLogic server. You can also *use step actions and breakpoints* in the modules to help identify problems.

Modules Container

For each Application server (for example: *Bill (HTTP port:8060)*), you have access to the XQuery modules that are visible to that server. When editing, executing, or debugging XQuery it is recommended to open the XQuery files from this **Modules** container.

Note: You can also manage resources for a MarkLogic database through a WebDAV connection, although it is not recommended if you work with XQuery files since imported modules may not be resolved correctly.

Requests Container

Each MarkLogic application server includes a **Requests** container. In this container, Oxygen XML Editor displays both queries that are stopped for debugging purposes and queries that are still running. To clean up the entire **Requests** container at the end of your session, right-click it and use the ***Cancel all requests*** *action*.

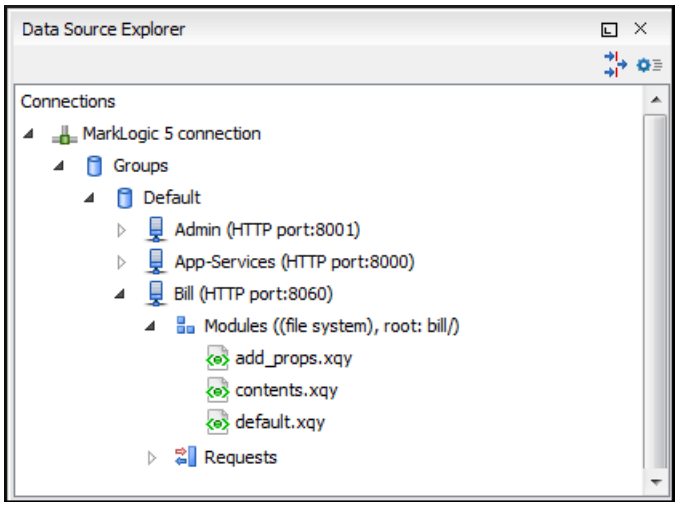

Figure 662: MarkLogic Connection in Data Source Explorer

Configuring a MarkLogic Database Connection

Note that this feature is available in Oxygen XML Editor Enterprise edition only.

Follow this procedure to configure the support for a MarkLogic database connection:

1. Download the MarkLogic driver from *MarkLogic Community site*.
2. *Configure MarkLogic Data Source drivers*.
3. *Configure a MarkLogic Connection*.
4. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

Related Information:

MarkLogic Development in Oxygen XML Editor on page 1311

How to Configure MarkLogic Data Source Drivers

Available in the Enterprise edition only.

Note: Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a data source for MarkLogic, follow this procedure:

1. Download the **XCC Java distribution** zip file from: *http://developer.marklogic.com/products/xcc*.
2. Unzip the downloaded archive.
3. *Open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Data Sources**.
4. Click the **New** button in the **Data Sources** panel.
5. Enter a unique name for the data source.
6. Select *MarkLogic* from the driver **Type** drop-down list.
7. Click the **Add Files** button and select the MarkLogic driver file from the `lib` folder of the archive that you downloaded and unzipped. The driver file name is `marklogic-xcc-{server_version}.jar`, where *{server_version}* is the MarkLogic server version.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to *configure your MarkLogic Connection*.

How to Configure a MarkLogic Connection

Available in the Enterprise edition only.

Note: Oxygen XML Editor supports MarkLogic version 4.0 or later.

To configure a connection to a MarkLogic database, follow these steps:

1. *Open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Data Sources**.

2. Click the + **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select a previously configured MarkLogic data source from the **Data Source** drop-down menu.
5. Enter the connection details.
   a) The host name or IP address of the installed MarkLogic engine in the **XDBC Host** field.

      Oxygen XML Editor uses XCC connector to interact with MarkLogic XDBC server and requires the basic authentication schema to be set. Starting with version MarkLogic 4.0 the default authentication method when you create an HTTP or WebDAV Server is *digest*, so make sure to change it to *basic*.
   b) Set the port number of the MarkLogic engine in the **Port** field. A MarkLogic XDBC application server must be configured on the server on this port. This XDBC server will be used to process XQuery expressions against the server. Later, if you want to change the XDBC server, instead of editing the configuration just use the ***Use it to execute queries*** *action* from Data Source Explorer.
   c) Set the user name to access the MarkLogic engine in the **User** field.
   d) Set the password to access the MarkLogic engine in the **Password** field.
   e) Optionally, in the **WebDAV URL** field, set the URL used for browsing the MarkLogic database in the ***Data Source Explorer*** *view*.

      The **Database** field specifies the database for which the XQuery expressions are executed. If you set this option to default, the database associated to the application server of the configured port is used.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

MarkLogic Development in Oxygen XML Editor

The Oxygen XML Editor support for MarkLogic includes features designed for developers, such as debugging XQuery transformations, remote and collaborative debugging, XQuery editing and validation, and an *XQuery builder* that helps to improve productivity.

Working with XQuery Files

MarkLogic supports working with XQuery files to create queries over stored XML content. You can open an XQuery file, configure a transformation scenario to match your MarkLogic connection, write the XQuery, and then execute it.

When editing XQuery modules stored on the MarkLogic server, the ***Outline*** *view* collects and displays all the functions from all imported modules. The *Content Completion Assistant* also presents all of these functions along with the latest built-in XQuery functions in accordance with the server version.

When developing queries for MarkLogic, it is best to open the resources from the ***Data Source Explorer*** *view*. When you execute or debug XQuery files opened from this view, imported modules can be resolved better by the MarkLogic server. Another advantage is that validation is automatically performed on the MarkLogic server, including any imported modules.

XQuery Debugging

Oxygen XML Editor allows you to use MarkLogic connections to debug real applications that use XQuery (for example, web applications that trigger XQuery executions). By setting the server in debug mode, you can intercept all the XQuery scripts that run on that server. Oxygen XML Editor connects to the MarkLogic server, shows you the running XQuery scripts, and allows you to debug them. The remote debugging support also allows you to debug collaboratively. Multiple users can participate in the same debugging session. You can start a debugging session and another user can continue it, and vice versa.

Working with Modules

MarkLogic has a concept of two types of XQuery modules, *library* and *main* modules. A *library* module is used to define functions. Library modules cannot be evaluated directly. They are imported, either from other library modules or from main modules. A *main* module is used as an entry point that can be executed as an XQuery program. For more information on these types of modules, see *XQuery Library Modules and Main Modules*.

When working with *library* modules, you need to create a validation scenario and associate it with the module. In the validation scenario you need to specify a main module as the entry point for validation. The modules need to be deployed on a MarkLogic server because Oxygen XML Editor will request the server to validate the modules.

To validate *library* modules stored on a MarkLogic server, follow these steps:

1. *Configure a MarkLogic database connection*.
2. Expand the MarkLogic connection in the ***Data Source Explorer*** *view* and open the *library* modules. The *main* module must also be opened from the ***Data Source Explorer*** *view*.
3. *Configure a validation scenario* for each *library* module. Specify the *main* module in the **URL of the file to validate** field.

   Result: Validation is done on the server that contains the *main* module. The *main* module and all other *library* modules involved in the validation must be saved. Otherwise, the server will validate what was saved on the server, without the uncommitted changes. Also, the *Content Completion Assistant* and the ***Outline*** *view* should now present the functions from all the modules.

Related Information:

Debugging with MarkLogic on page 1312
Configuring a MarkLogic Database Connection on page 1310

Debugging with MarkLogic

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:

1. Configure a *MarkLogic data source* and a *MarkLogic connection*.
2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the *Task Server* section of the server control console (the switch *debug allow*). If the debugging is not activated, the MarkLogic server reports a `DBG-TASKDEBUGALLOW` error.

   Note: An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by selecting the ***Use it to execute queries*** *action* from the contextual menu in the ***Data Source Explorer*** *view*.
3. Open the XQuery file and start the debugging process.

   - If you want to debug an XQuery file stored on the MarkLogic server, we recommend you to use the ***Data Source Explorer*** *view* and open the file from the application server that is involved in the debugging process. This improves the resolving of any imported modules.
   - The MarkLogic XQuery debugger integrates seamlessly into the *XQuery Debugger perspective*. If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to *debug the scenario* directly.
   - Otherwise, switch to the **XQuery Debugger** *perspective*, open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the *debug control toolbar*.

     For general information about how a debugging session is started and controlled, see the *Working with the Debugger* section.

In a MarkLogic debugging session, you can use step actions and *breakpoints* to help identify problems. When you *add a breakpoint* on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for *breakpoints* you add either in the main XQuery (which you can open locally or from the server) or for *breakpoints* you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see *Using Breakpoints for Debugging Queries that Import Modules with MarkLogic* on page 1313.

Remote Debugging with MarkLogic

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging

queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.

Important: When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

Related Information:

MarkLogic Development in Oxygen XML Editor on page 1311

Configuring a MarkLogic Database Connection on page 1310

Using Breakpoints for Debugging Queries that Import Modules with MarkLogic

When debugging queries that imports modules stored in the database, it is recommended to place *breakpoints* in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the *breakpoints* in all the modules will be considered. Also, make sure that there are no other opened modules that are not involved in the current debugging session.

To place *breakpoints* in the modules, use the following procedure:

1. In the ***Data Source Explorer*** *view*, open all the modules from the  **Modules** container of the *XDBC application server* that performs the debugging.
2. *Set breakpoints* in the module as needed.
3. *Continue debugging* the query.

If you get a warning that the *breakpoints* failed to initialize, try the following solutions:

- Check the ***Breakpoints*** *view* and make sure there are no older *breakpoints* (set on resources that are not part of the current debugging context).
- Make sure you open the modules from the context of the application server that does the debugging and place *breakpoints* there.

MarkLogic Development in Oxygen XML Editor on page 1311

Peculiarities and Limitations of the MarkLogic Debugger

MarkLogic debugger has the following peculiarities and limitations:

- Debugging support is only available for MarkLogic server versions 4.0 or newer.
- For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: *'0.9-ml' (inherited from MarkLogic 3.2)*, *'1.0-ml'*, and *'1.0'*.
- All declared variables are presented as strings. The **Value** column of the **Variables** view contains the expression from the variable declaration. It can be evaluated by copying the expression with the **Copy value** action from the contextual menu of *the* ***Variables*** *view* and pasting it in *the* ***XWatch*** *view*.
- There is no support for *output to source mapping*.
- There is no support for *showing the trace*.
- You can only set *breakpoints* in imported modules in one of the following cases:
  - When you open the module from the context of the application server involved in the debugging, using the ***Data Source Explorer*** *view*.
  - When the debugger automatically opens the modules in the Editor.
- No *breakpoints* are set in modules from the same server that are not involved in the current debugging session.
- No support for *profiling* when an XQuery transformation is executed in the debugger.

MarkLogic Contextual Menu Actions

While browsing MarkLogic connections in the ***Data Source Explorer*** *view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Container Level Nodes

Enable Debug Mode

Switches the server to a debugging mode. For more information, see *MarkLogic debugging sessions*.

Use it to Execute Queries

The server will be used to process XQuery expressions against it.

Refresh

Performs a refresh on the selected node.

Module or Folder Level Nodes

Export

Allows you to export the folder on the remote connection to a local folder.

Refresh

Performs a refresh on the selected node.

Requests Level Nodes

Refresh

Performs a refresh on the selected node.

Cancel all requests

Cancels all queries that are either running or stopped on the application server. You can use this action to clean up the entire **Requests** container at the end of your sessions.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Refresh

Performs a refresh on the selected node.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

Debugging with MarkLogic on page 1312

Documentum xDB (X-Hive/DB) 10 Database Connections

Oxygen XML Editor includes support for Documentum xDB (X-Hive/DB) 10 database connections. Oxygen XML Editor allows you to browse the structure of a Documentum xDB (X-Hive/DB) 10 database in the ***Data Source Explorer*** *view* and perform various operations on the resources in the repository.

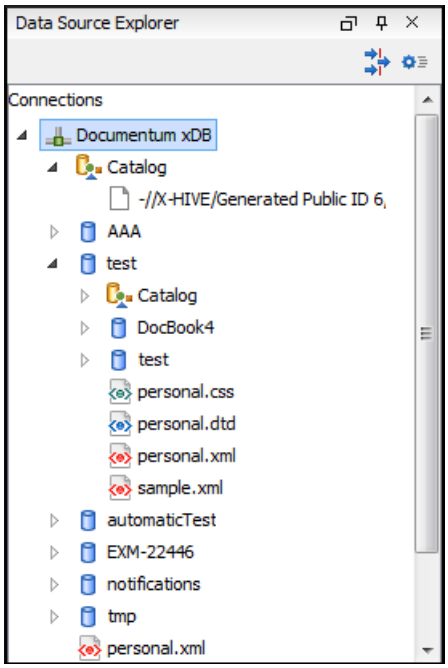

Figure 663: Documentum xDB (X-Hive/DB) 10 Connection

Configuring a Documentum xDB (X-Hive/DB) 10 Database Connection

Follow this procedure to configure the support for a Documentum xDB (X-Hive/DB) 10 database:

1. *Configure Documentum xDB Data Source drivers*.
2. *Configure a Documentum xDB Connection*.
3. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure Documentum xDB (X-Hive/DB) 10 Data Source Drivers

Available in the Enterprise edition only. For this procedure, you need to already have a Documentum xDB server installed.

To configure a data source for Documentum xDB (X-Hive/DB) 10, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Data Sources** panel.
3. Enter a unique name for the data source.
4. Select *Documentum xDB* from the driver **Type** drop-down menu.

5. Click the **Add** button to add the driver files.

   The driver files for the Documentum xDB (X-Hive/DB) 10 database are found in the Documentum xDB (X-Hive/DB) 10 lib directory from the server installation folder:

   - `antlr-runtime.jar`
   - `aspectjrt.jar`
   - `icu4j.jar`
   - `xhive.jar`
   - `google-collect.jar`
6. Click the **OK** button to finish the data source configuration.
7. Continue on to *configure your Documentum xDB (X-Hive/DB) 10 connection*.

How to Configure an Documentum xDB (X-Hive/DB) 10 Connection

To configure a connection to a Documentum xDB (X-Hive/DB) 10 database, follow these steps:

Note: The bootstrap type of X-Hive/DB connections is not supported in Oxygen XML Editor. The following procedure explains the `xhive://` protocol connection type.

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select a previously configured data source from the **Data Source** drop-down menu.
5. Enter the connection details.
   a) Set the URL property of the connection in the **URL** field.

      If the property is a URL of the form *xhive://host:port*, the Documentum xDB (X-Hive/DB) 10 connection will attempt to connect to a Documentum xDB (X-Hive/DB) 10 server running behind the specified TCP/IP port.
   b) Set the user name to access the Documentum xDB (X-Hive/DB) 10 engine in the **User** field.
   c) Set the password to access the Documentum xDB (X-Hive/DB) 10 engine in the **Password** field.
   d) Set the name of the database to access from the Documentum xDB (X-Hive/DB) 10 engine in the **Database** field.
   e) Select the **Run XQuery in read / write session (with committing)** checkbox if you want to end the session with a commit. Otherwise, the session ends with a rollback.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

Documentum xDB (X-Hive/DB) 10 Contextual Menu Actions

While browsing Documentum xDB (X-Hive/DB) 10 connections in the ***Data Source Explorer** view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources** preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

Add Library

Allows you to add a new library.

Insert XML Instance

Allows you to add a new XML resource directly into the database root. See *Documentum xDB (X-Hive/DB) 10 Parser Configuration* for more details.

Insert non-XML Instance

Allows you to add a new non-XML resource directly in the database root.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Catalog Level Nodes

Add AS Models

Allows you to add a new abstract schema model to the selected catalog.

Export

Allows you to export the folder on the remote connection to a local folder.

Set Default Schema

Allows you to set a default DTD to be used for parsing. It is not possible to set a default XML Schema.

Clear Default Schema

Allows you to clear the default DTD. The action is available only if there is a DTD set as default.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Container (Library) Level Nodes

New File

Creates a new file on the connection, in the current folder.

Add Library

Allows you to add a new library.

Import Folders

Imports folders on the server.

Add Local Catalog

Adds a catalog to the selected library. By default, only the root-library has a catalog, and all models are stored there.

Insert XML Instance

Allows you to add a new XML resource directly into the database root. See *Documentum xDB (X-Hive/DB) 10 Parser Configuration* for more details.

Insert non-XML Instance

Allows you to add a new non-XML resource directly in the database root.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Save As

Allows you to save the selected resource as a file on disk.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Add AS model

Allows you to add an XML schema to the selected XML resource.

Set AS model

Allows you to set an active AS model for the selected XML resource.

Clear AS model

Allows you to clear the active AS model of the selected XML resource.

Properties

Displays the resource properties. Available only for XML resources.

Set Default Schema

Allows you to set the selected DTD to be used as default for parsing. The action is available only for DTD.

Clear Default Schema

Allows you to unset the selected DTD. The action is available only if the selected DTD is the current default to be used for parsing.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

Documentum xDB (X-Hive/DB) 10 Parser Configuration for Adding XML Instances

When an XML instance document is added to a Documentum xDB (X-Hive/DB) 10 connection or library, it is parsed with an internal XML parser of the database server. The following options are available for configuring this parser:

- DOM Level 3 parser configuration parameters. More about each parameter can be found here: *DOM Level 3 Configuration*.
- Documentum xDB (X-Hive/DB) 10 specific parser parameters (for more information, consult the Documentum xDB (X-Hive/DB) 10 manual):
  - **xhive-store-schema** - If selected, the corresponding DTD or XML schemas are stored in the catalog during validated parsing.
  - **xhive-store-schema-only-internal-subset** - Stores only the internal sub-set of the document (not an external sub-set). This option modifies the **xhive-store-schema** (only has a function when that parameter is set to true, and when a DTD is involved). Select this option if you only want to store the internal sub-set of the document (not the external sub-set).
  - **xhive-ignore-catalog** - Ignores the corresponding DTD and XML schemas in the catalog during validated parsing.
  - **xhive-psvi** - Stores **psvi** information about elements and attributes. Documents parsed with this feature turned on give access to **psvi** information and enable support of data types by XQuery queries.
  - **xhive-sync-features** - With this convenience setting turned on, parameter settings of **XhiveDocumentIf** are synchronized with the parameter settings of **LSParser**. Note that parameter settings **xhive-psvi** and **schema-location** are always synchronized.

Troubleshooting Documentum xDB

Question:

I am able to access my XML Database in the ***Data Source Explorer*** and open files for reading but when I try to save changes to a file back into the database, I receive the following error: **"Cannot save the file. DTD factory class org.apache.xerces.impl.dv.dtd.DTDDVFactoryImpl does not extend from DTDDVFactory"**. How can I fix this?

Answer:

`xhive.jar` contains a MANIFEST.MF with a classpath:

```
Class-Path: core/antlr-runtime.jar core/aspectjrt.jar core/fastutil-shrinked.jar
    core/google-collect.jar core/icu4j.jar core/lucene-regex.jar core/lucene.jar
    core/serializer.jar core/xalan.jar core/xercesImpl.jar
```

Since the driver was configured to use `xhive.jar` directly from the *xDB* installation (where many other *JARS* are located), `core/xercesImpl.jar` from the *xDB* installation directory is loaded even though it is not specified in the list of *JARS* from the data source driver configuration (it is in the classpath from `xhive.jar` - `MANIFEST.MF`). A simple workaround for this issue is to copy **ONLY** the *JAR* files used in the driver configuration to a separate folder and configure the data source driver to use them from there.

MySQL Database Connections

Oxygen XML Editor includes support for MySQL database connections. Oxygen XML Editor allows you to browse the structure of a SQL Server database in the ***Data Source Explorer*** *view*, open tables in the ***Table Explorer*** *view*, and perform various operations on the resources in the repository.

Configuring a MySQL Database Connection

To configure the support for a MySQL database, follow this procedure:

1. *Configure MySQL Data Source drivers*.
2. *Configure a MySQL Connection.*
3. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure MySQL Data Source Drivers

To connect to a MySQL server, you need to create a generic JDBC type data source based on *the MySQL JDBC driver available on the MySQL website*.

To configure this data source, follow these steps:

1. Go to *https://www.oxygenxml.com/database_drivers.html* and download the appropriate MySQL driver.
2. *Open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.

   The dialog box for configuring a data source is opened.

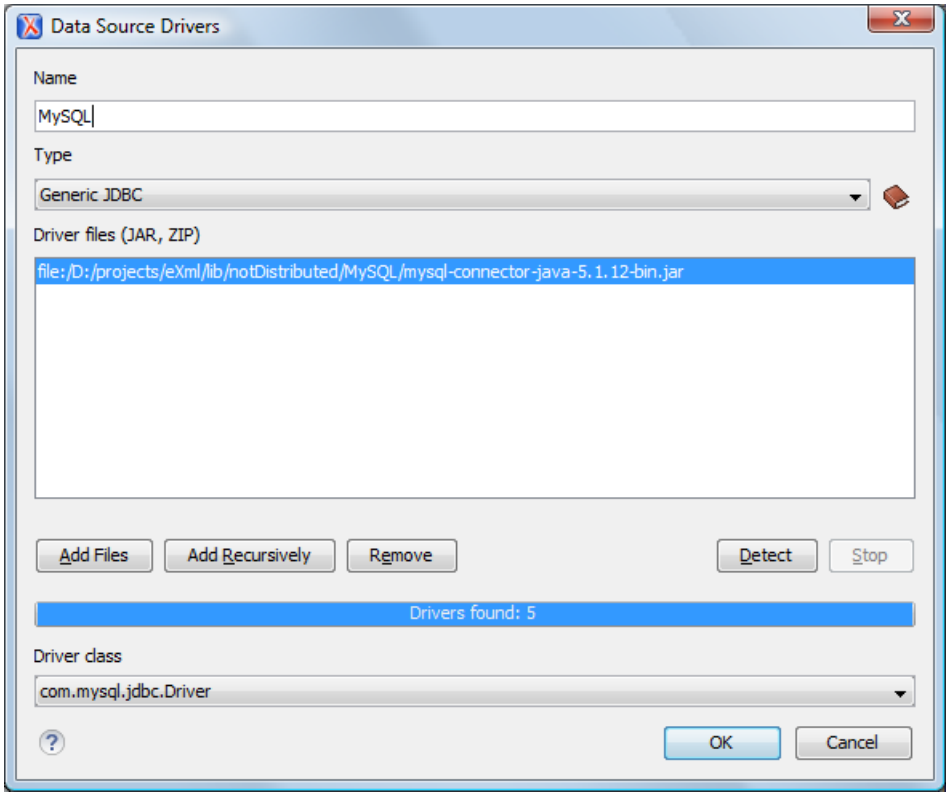

Figure 664: Data Source Drivers Configuration Dialog Box

4. Enter a unique name for the data source.
5. Select *Generic JDBC* in the driver **Type** drop-down list.
6. Click the **Add Files** button and select the MySQL driver file that you downloaded.

   The driver file for the MySQL server is called `mysql-com.jar`.
7. Select the most appropriate **Driver class**.
8. Click the **OK** button to finish the data source configuration.

9. Continue on to *configure your MySQL connection*.

How to Configure a MySQL Connection

To configure a connection to a MySQL server, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

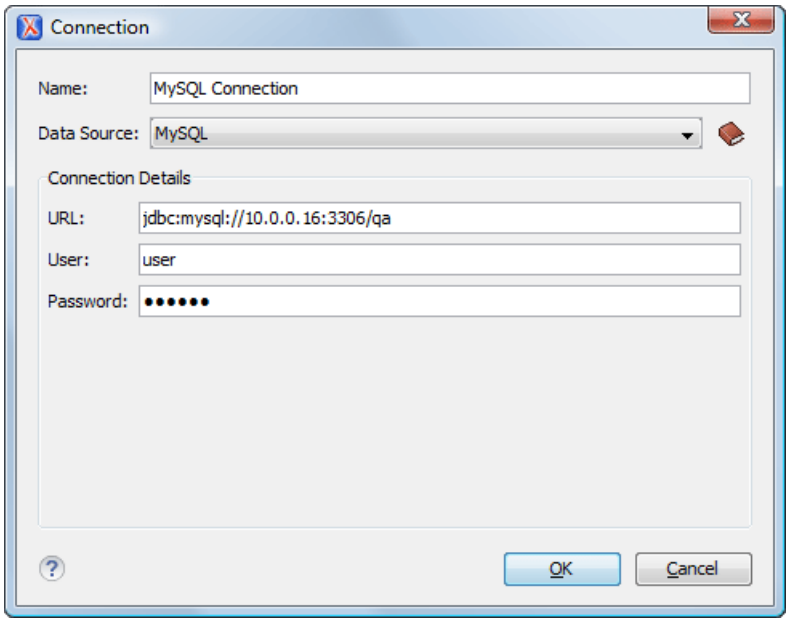

Figure 665: Connection Configuration Dialog Box

3. Enter a unique name for the connection.
4. Select the *MySQL* data source in the **Data Source** drop-down list.
5. Enter the connection details.
   a) Enter the URL of the MySQL server.
   b) Enter the user name for the connection to the MySQL server.
   c) Enter the password for the connection to the MySQL server.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

Generic JDBC Database Connections

Oxygen XML Editor includes support for Generic JDBC database connections.

Configuring a Generic JDBC Database Connection

To configure the support for a generic JDBC database, follow this procedure:

1. *Configure Generic JDBC Data Source drivers*.
2. *Configure a Generic JDBC Connection*.
3. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure Generic JDBC Data Source Drivers

Starting with version 17, Oxygen XML Editor comes bundled with Java 8, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a generic JDBC data source, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Data Sources** panel.
3. Enter a unique name for the data source.
4. Select *Generic JDBC* in the driver **Type** drop-down list.
5. Add the driver file(s) using the **Add Files** button.
6. Select the most appropriate **Driver class**.
7. Click the **OK** button to finish the data source configuration.
8. Continue on to *configure a generic JDBC connection*.

How to Configure a Generic JDBC Connection

To configure a connection to a generic JDBC database, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select the *Generic JDBC* data source in the **Data Source** drop-down menu.
5. Enter the connection details.
   a) Enter the URL of the generic JDBC database, with the following format:`jdbc: <subprotocol>: <subname>`.
   b) Enter the user name for the connection to the generic JDBC database.
   c) Enter the password for the connection to the generic JDBC database.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

JDBC-ODBC Database Connections

Oxygen XML Editor includes support for JDBC-ODBC database connections.

How to Configure a JDBC-ODBC Connection

Starting with version 17, Oxygen XML Editor comes bundled with Java 8, which does not provide built-in access to JDBC-ODBC data sources. To access such sources, you need to find an alternative JDBC-ODBC bridge or use a platform-independent distribution of Oxygen XML Editor along with a Java VM version 7 or 6.

To configure a connection to an ODBC data source, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.

   The dialog box for configuring a database connection is displayed.

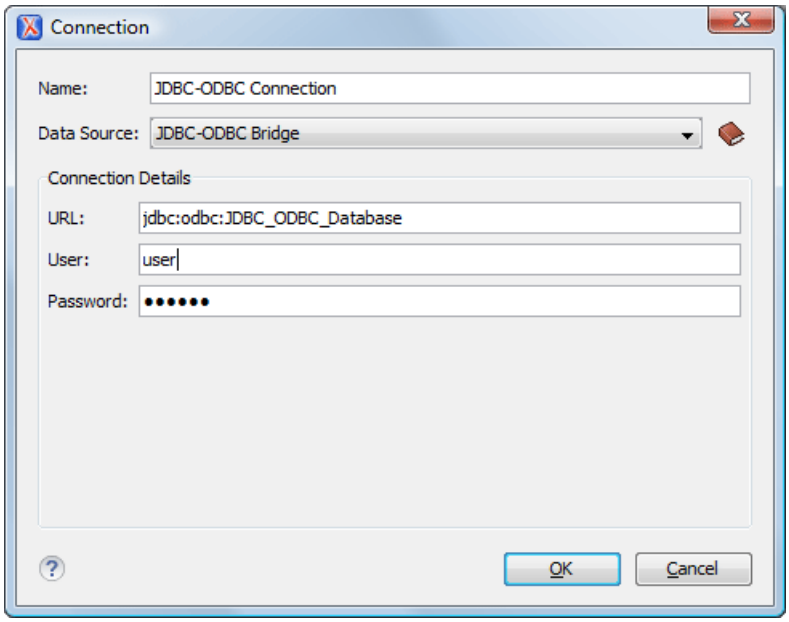

Figure 666: Connection Configuration Dialog Box

3. Enter a unique name for the connection.
4. Select *JDBC-ODBC Bridge* in the **Data Source** drop-down list.
5. Enter the connection details.
   a) Enter the URL of the ODBC source.
   b) Enter the user name of the ODBC source.
   c) Enter the password of the ODBC source.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

BaseX Database Connections

Oxygen XML Editor includes support for BaseX database connections using a WebDAV connection. BaseX is a light-weight XML database engine and XQuery processor. Oxygen XML Editor allows you to browse the structure of a BaseX database in the ***Data Source Explorer*** *view* and perform XQuery executions.

How to Configure a BaseX Connection

To configure a BaseX connection, follow these steps:

1. First of all, make sure the BaseX HTTP Server is started. For details about starting the BaseX HTTP server, go to *http://docs.basex.org/wiki/Startup#BaseX_HTTP_Server*. The configuration file for the HTTP server is named `.basex` and is located in the BaseX installation directory. This file helps you to find out which port the HTTP server using. The default port for BaseX WebDAV is 8984.
2. To ensure that everything is functioning, open a WebDAV URL inside a browser and check to see if it works. For example, the following URL retrieves a document from a database named TEST: `http://localhost:8984/webdav/TEST/etc/factbook.xml`.
3. Once you are sure that the BaseX WebDAV service is working, you can configure the WebDAV connection in Oxygen XML Editor as described in *How to Configure a WebDAV Connection* on page 1326. The WebDAV URL should resemble this: `http://{hostname }:{port}/webdav/`. If the BaseX server is running on your own machine and it has the default configuration, the data required by the WebDAV connection is:
   - WebDAV URL: `http://localhost:8984/webdav`
   - User: `admin`
   - Password: `admin`

4. Once the WebDAV connection is created, to view your connection, go to the ***Data Source Explorer*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

BaseX Contextual Menu Actions

While browsing BaseX connections in the ***Data Source Explorer*** *view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

New Folder

Creates a new folder on the connection.

Import Files

Allows you to add a new file on the connection, in the current folder.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

Base X XQJ Connection

XQuery execution is possible in a BaseX connection through an XQJ connection.

Important: The XQJ connector is only capable of running XQuery 1.0 scrips, therefore XQuery 3.0 and 3.1 scripts are not supported.

BaseX XQJ Data Source

First of all, create an XQJ data source as described in *How to Configure an XQJ Data Source* on page 1326.
The BaseX XQJ API-specific files that must be added in the configuration dialog box are `xqj-api-1.0.jar`, `xqj2-0.1.0.jar` and `basex-xqj-1.2.3.jar` (the version names of the *JAR* file may differ). These libraries can be downloaded from *xqj.net/basex/basex-xqj-1.2.3.zip*. As an alternative, you can also find the libraries in the BaseX installation directory, in the **lib** sub-directory.

BaseX XQJ Connection

The next step is to create an *XQJ connection*.

For a default BaseX configuration, the following connection details apply (you can modify them when necessary):

- **Port**: 1984
- **serverName**: localhost
- **user**: admin
- **password**: admin

XQuery Execution

Now that the XQJ connection is configured, open the XQuery file you want to execute in Oxygen XML Editor and create an *XQuery Transformation* on page 1130. In the **Transformer** drop-down menu, select the name of the XQJ connection you created. Apply the transformation scenario and the XQuery will be executed.

How to Configure an XQJ Data Source

Any transformer that offers an XQJ API implementation can be used when validating XQuery or transforming XML documents. An example of an XQuery engine that implements the XQJ API is *Zorba*.

1. If your XQJ Implementation is native, make sure the directory containing the native libraries of the engine is added to your system environment variables: to PATH - on Windows, to LD_LIBRARY_PATH - on Linux, or to DYLD_LIBRARY_PATH - on OS X. Restart Oxygen XML Editor after configuring the environment variables.
2. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.
4. Enter a unique name for the data source.
5. Select **XQuery API for Java (XQJ)** in the **Type** combo box.
6. Press the **Add** button to add XQJ API-specific files.

   You can manage the driver files using the **Add**, **Remove**, **Detect**, and **Stop** buttons.

   Oxygen XML Editor detects any implementation of *javax.xml.xquery.XQDataSource* and presents it in **Driver class** field.
7. Select the most suited driver in the **Driver class** combo box.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to *configure the XQJ connection*.

How to Configure an XQJ Connection

The steps for configuring an XQJ connection are the following:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select one of the previously configured *XQJ data sources* in the **Data Source** combo box.
5. Fill-in the connection details.

   The properties presented in the connection details table are automatically detected depending on the selected data source.
6. Click the **OK** button to finish the connection configuration.

WebDAV Connections

Oxygen XML Editor includes support for WebDAV server connections. Oxygen XML Editor allows you to browse the structure of a WebDAV connection in the ***Data Source Explorer** view* and perform various operations on the resources in the repository.

How to Configure a WebDAV Connection

By default, Oxygen XML Editor contains built-in data source drivers for **WebDAV** connections. Based on this data source, you can create a WebDAV connection for browsing and editing data from a database that provides a WebDAV interface. The connection is available in the ***Data Source Explorer** view*.

To configure a WebDAV connection, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select one of the WebDAV data sources in the **Data Source** drop-down menu.
5. Enter the connection details:
   a) Set the URL to the WebDAV repository in the field **WebDAV URL**.
   b) Set the user name that is used to access the WebDAV repository in the **User** field.
   c) Set the password that is used to access the WebDAV repository in the **Password** field.
6. Click the **OK** button to finish the connection configuration.
7. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

   For more information about the WebDAV support in Oxygen XML Editor, watch our video demonstration:

WebDAV Contextual Menu Actions

While browsing WebDAV connections in the ***Data Source Explorer** view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources** preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

New Folder

Creates a new folder on the connection.

Import Files

Allows you to add a new file on the connection, in the current folder.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files** dialog box* that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

SQL Execution Support

The database support in Oxygen XML Editor includes support for writing SQL statements, syntax highlighting, *folding*, and dragging and dropping from the ***Data Source Explorer*** *view*. It also includes transformation scenarios for executing the statements, and the results are displayed in the ***Table Explorer*** *view*.

Drag and Drop from Data Source Explorer View

Drag and drop operations from the ***Data Source Explorer*** *view* to the SQL Editor allows you to create SQL statements quickly by inserting the names of tables and columns in the SQL statements.

1. Configure a database connection (see the specific procedure for your database server in the *Database Connection Support* section).
2. Browse to the table you will use in your statement.
3. Drag the table or a column of the table into the editor where a SQL file is open.

   Drag and drop actions are available both on the table and on its fields. A pop-up menu is displayed in the SQL editor.

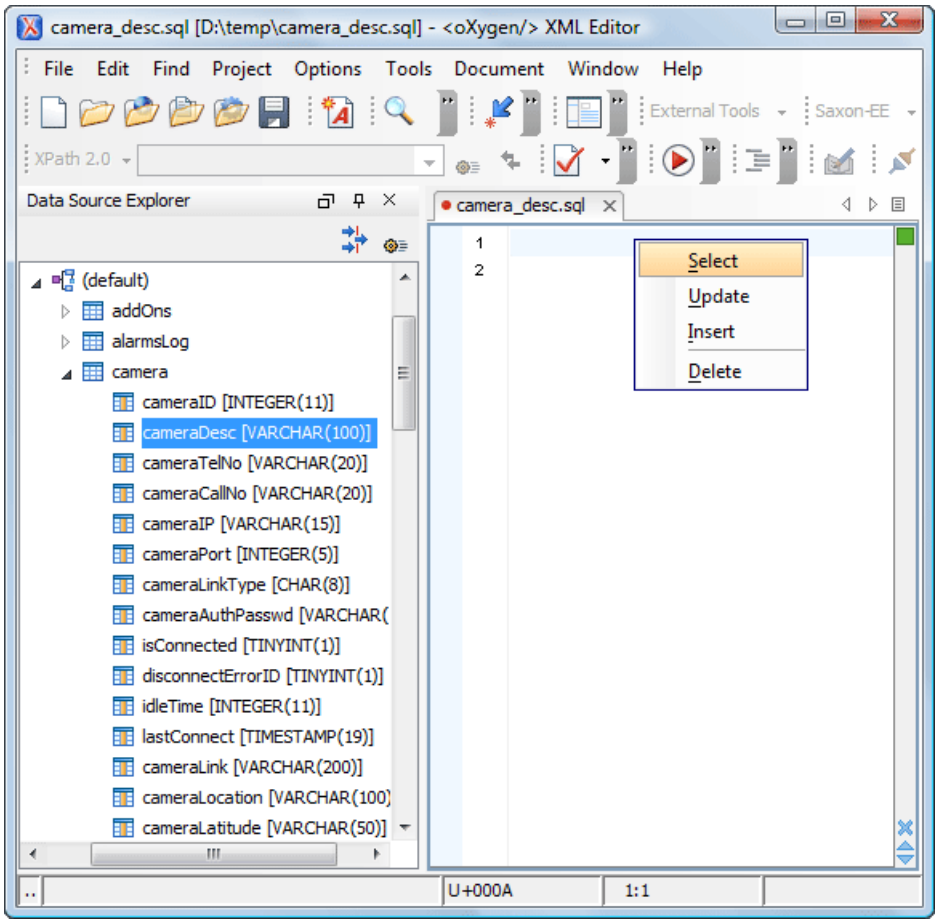

Figure 667: SQL Statement Editing with Drag and Drop

4. Select the type of statement from the pop-up menu.

   Depending on your choice, dragging a table results in one of the following statements being inserted into the document:

   - SELECT `*field1*`,`*field2*`,.... FROM `*catalog*`.`*table*` (for example: `SELECT `DEPT`,`DEPTNAME`,`LOCATION` FROM `camera`.`cameraDesc``)
   - UPDATE `*catalog*`.`*table*` SET `*field1*`=,`*field2*`=,.... (for example: `UPDATE `camera`.`cameraDesc` SET `DEPT`=, `DEPTNAME`=, `LOCATION`=`)
   - INSERT INTO`*catalog*`.`*table*` (`*field1*`,`*field2*`,....) VALUES (,,) (for example: `INSERT INTO `camera`.`cameraDesc` (`DEPT`,`DEPTNAME`,`LOCATION`) VALUES (, , ))`

- DELETE FROM `*catalog*`.`*table*` (for example: `DELETE FROM `camera`.`cameraDesc``)

Depending on your choice, dragging a column results in one of the following statements being inserted into the document:

- SELECT `*field*` FROM `*catalog*`.`*table*` (for example: `SELECT `DEPT` FROM `camera`.`cameraDesc``)
- UPDATE `*catalog*`.`*table*` SET `*field*`= (for example: `UPDATE `camera`.`cameraDesc` SET `DEPT`=`)
- INSERT INTO`*catalog*`.`*table*` (`*field1*`) VALUES () (for example: `INSERT INTO `camera`.`cameraDesc` (`DEPT`) VALUES ()`)
- DELETE FROM `*catalog*`.`*table*` (for example: `DELETE FROM `camera`.`cameraDesc` WHERE `DEPT`=`)

SQL Validation

SQL validation support is offered for IBM DB2. Note that if you choose a connection that does not support SQL validation, you will receive a warning when trying to validate. The SQL document is validated using the connection from the associated transformation scenario.

Executing SQL Statements

The steps for executing an SQL statement on a relational database are as follows:

1. Configure a *transformation scenario* using the **Configure Transformation Scenario(s)** action from the toolbar or the **Document** > **Transformation** menu.

   A SQL transformation scenario needs a database connection. You can configure a connection using the **Preferences** button from the SQL transformation dialog box.

   The dialog box contains the list of existing scenarios that apply to SQL documents.
2. Set parameter values for SQL placeholders using the **Parameters** button from the SQL transformation dialog box.

   For example, in `SELECT * FROM `test`.`department` where DEPT = ? or DEPTNAME = ?` the two parameters can be configured for the place holders (?) in the transformation scenario.

   When the SQL statement is executed, the first placeholder is replaced with the value set for the first parameter in the scenario, the second placeholder is replaced by the second parameter value, and so on.

   Restriction: When a stored procedure is called in an SQL statement executed on an SQL Server database, mixing inline parameter values with values specified using the **Parameters** button of the scenario dialog box is not recommended. This is due to a limitation of the SQL Server driver for Java applications. An example of stored procedure that is not recommended: `call dbo.Test(22, ?)`.
3. Execute the SQL scenario by clicking the **OK** or **Apply associated** button.

   The result of a SQL transformation is *displayed in a view* at the bottom of the Oxygen XML Editor window.
4. View more complex return values of the SQL transformation in a separate editor panel.

   A more complex value returned by the SQL query (for example, an *XMLTYPE* or *CLOB* value) cannot be displayed entirely in the result table.

   a) Right-click the cell containing the complex value.
   b) Select the action **Copy cell** from the contextual menu.
   The action copies the value in the clipboard.
   c) Paste the value into an appropriate editor.

   For example, you can paste the value in an opened XQuery editor panel of Oxygen XML Editor.

XQuery and Databases

XQuery is a native XML query language that is useful for querying XML views of relational data to create XML results. It also provides the mechanism to efficiently and easily extract information from Native XML Databases (NXD) and relational data. The following database systems supported in Oxygen XML Editor offer XQuery support:

- *Native XML Databases:*

- Berkeley DB XML
- eXist
- MarkLogic (validation support available starting with version 5)
- Documentum xDB (X-Hive/DB) 10

- *Relational Databases:*
  - IBM DB2
  - Microsoft SQL Server (validation support not available)
  - Oracle (validation support not available)

Related Information:
Editing XQuery Documents on page 832

Build Queries with Drag and Drop from the Data Source Explorer View

When a query is edited in the XQuery editor, the XPath expressions can be composed quickly by dragging them from the ***Data Source Explorer*** *view* and dropping them into the editor panel.

1. *Configure the data source drivers* for the particular relational database in the ***Data Sources*** *preferences page*.
2. *Configure the connection* for the particular relational database in the ***Data Sources*** *preferences page*.
3. Browse the connection in the ***Data Source Explorer*** *view*, expanded to the table or column that you want to insert in the query.
4. Drag the table or column name to the XQuery editor panel.
5. Drop the table or column name where the XPath expression is needed.

An XPath expression that selects the dragged name is inserted in the XQuery document at the cursor position.

XQuery Validation When Connected to a Database

With Oxygen XML Editor, you can validate your XQuery documents when connected to a database. When you open an XQuery document from a connection that supports validation (for example, MarkLogic, or eXist), by default Oxygen XML Editor uses this connection for validation. If you open an XQuery file using a MarkLogic connection, the validation resolves imports better.

Related Information:
XQuery Validation on page 832

XQuery Transformation for Databases

XQuery is designed to retrieve and interpret XML data from any source, whether it is a database or document. Data is stored in relational databases but it is often required that the data be extracted and transformed as XML when interfacing to other components and services. Also, it is an XPath-based querying language supported by most NXD vendors. To perform a query, you need an XQuery transformation scenario.

1. *Configure the data source drivers and the connection* for the particular database.
2. Configure an XQuery transformation scenario.
   a) Click the **Configure Transformation Scenario** toolbar button or go to menu **Document** > **Transformation** > **Configure Transformation Scenario**.

      The ***Configure Transformation Scenario*** *dialog box* is opened.
   b) Click the **New** button toward the bottom of the dialog box.
   c) Select ***XML Transformation with XQUERY***.

      The **New Scenario** dialog box for configuring an XQuery scenario is opened.

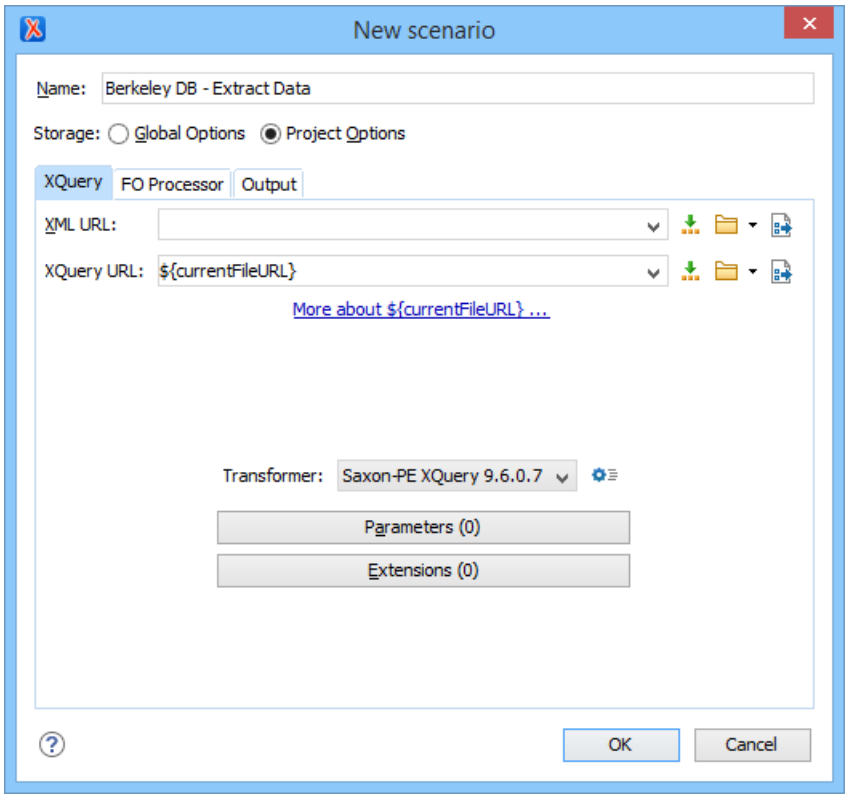

Figure 668: New Scenario Dialog Box

d) Insert the scenario name in the dialog box for editing the scenario.
e) Choose the database connection in the **Transformer** drop-down list.
f) Configure any other parameters as needed.

   For an XQuery transformation, the output tab has an option called **Sequence** that allows you to run an XQuery in lazy mode. The amount of data extracted from the database is controlled from the ***Size limit on Sequence view*** *option* in the **XQuery** preferences page. If you choose **Perform FO Processing** in the **FO Processor** tab, the **Sequence** option is ignored.
g) Click the **OK** button to finish editing the scenario.

Once the scenario is associated with the XQuery file, the query can include calls to specific XQuery functions that are implemented by that engine. The available functions depend on the target database engine selected in the scenario. For example, for eXist and Berkeley DB XML, the *Content Completion Assistant* lists the functions supported by that database engine. This is useful for only inserting calls to the supported functions (standard XQuery functions or extension ones) into the query .

Note: An XQuery transformation is executed against a Berkeley DB XML server as a transaction using the query transaction support of the server.

3. Run the transformation scenario.

   To view a more complex value returned by the query that cannot be entirely displayed in the XQuery query result table at the bottom of the Oxygen XML Editor window (for example, an XMLTYPE or CLOB value), do the following:

   - Right-click that table cell.
   - Select the **Copy cell** action from the contextual menu to copy the value into the clipboard.
   - Paste the value wherever you need it (for example, in an opened XQuery editor panel of Oxygen XML Editor).

Related Information:

XML Transformation with XQuery on page 1105
This type of transformation specifies the transform parameters and location of an XQuery file that is applied to the edited XML document.

XQuery XQJ Transformation on page 1333

XQuery XQJ Transformation

XQuery API for Java (XQJ) refers to the common Java API for the W3C XQuery 1.0 specification. The XQJ API enables you to execute XQuery against an XML data source.

Important: The XQJ connector is only capable of running XQuery 1.0 scrips, therefore XQuery 3.0 and 3.1 scripts are not supported.

Oxygen XML Editor supports any transformer that offers an XQJ API implementation and it be used for validating XQuery or transforming XML documents.

To configure the support for XQJ, do the following:

1. *Configure an XQJ Data Source*.
2. *Configure an XQJ Connection*.
3. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure an XQJ Data Source

Any transformer that offers an XQJ API implementation can be used when validating XQuery or transforming XML documents. An example of an XQuery engine that implements the XQJ API is *Zorba*.

1. If your XQJ Implementation is native, make sure the directory containing the native libraries of the engine is added to your system environment variables: to PATH - on Windows, to LD_LIBRARY_PATH - on Linux, or to DYLD_LIBRARY_PATH - on OS X. Restart Oxygen XML Editor after configuring the environment variables.
2. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
3. Click the **New** button in the **Data Sources** panel.
4. Enter a unique name for the data source.
5. Select **XQuery API for Java (XQJ)** in the **Type** combo box.
6. Press the **Add** button to add XQJ API-specific files.

   You can manage the driver files using the **Add**, **Remove**, **Detect**, and **Stop** buttons.

   Oxygen XML Editor detects any implementation of *javax.xml.xquery.XQDataSource* and presents it in **Driver class** field.
7. Select the most suited driver in the **Driver class** combo box.
8. Click the **OK** button to finish the data source configuration.
9. Continue on to *configure the XQJ connection*.

How to Configure an XQJ Connection

The steps for configuring an XQJ connection are the following:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. Click the **New** button in the **Connections** panel.
3. Enter a unique name for the connection.
4. Select one of the previously configured *XQJ data sources* in the **Data Source** combo box.
5. Fill-in the connection details.

   The properties presented in the connection details table are automatically detected depending on the selected data source.
6. Click the **OK** button to finish the connection configuration.

XQuery Database Debugging

Oxygen XML Editor includes a debugging interface that helps you to detect and solve problems with XQuery transformations that are executed against MarkLogic and Berkeley DB XML databases.

For more information about the debugging support in Oxygen XML Editor, see *Debugging XSLT Stylesheets and XQuery Documents* on page 1357.

Debugging with MarkLogic

Oxygen XML Editor includes support for debugging XQuery transformations that are executed against a MarkLogic database.

To use a debugging session against the MarkLogic engine, follow these steps:

1. Configure a *MarkLogic data source* and a *MarkLogic connection*.
2. Make sure that the debugging support is enabled in the MarkLogic server that Oxygen XML Editor accesses. On the server side, debugging must be activated in the XDBC server and in the *Task Server* section of the server control console (the switch *debug allow*). If the debugging is not activated, the MarkLogic server reports a `DBG-TASKDEBUGALLOW` error.

   Note: An XDBC application server must be running to connect to the MarkLogic server and this XDBC server will be used to process XQuery expressions against the server. You can change the XDBC application server that Oxygen XML Editor uses to process XQuery expressions by selecting the ***Use it to execute queries*** *action* from the contextual menu in the ***Data Source Explorer*** *view*.
3. Open the XQuery file and start the debugging process.
   - If you want to debug an XQuery file stored on the MarkLogic server, we recommend you to use the ***Data Source Explorer*** *view* and open the file from the application server that is involved in the debugging process. This improves the resolving of any imported modules.
   - The MarkLogic XQuery debugger integrates seamlessly into the *XQuery Debugger perspective*. If you have a MarkLogic validation scenario configured for the XQuery file, you can choose to *debug the scenario* directly.
   - Otherwise, switch to the **XQuery Debugger** *perspective*, open the XQuery file in the editor, and select the MarkLogic connection in the XQuery engine selector from the *debug control toolbar*.

     For general information about how a debugging session is started and controlled, see the *Working with the Debugger* section.

In a MarkLogic debugging session, you can use step actions and *breakpoints* to help identify problems. When you *add a breakpoint* on a line where the debugger never stops, Oxygen XML Editor displays a warning message. These warnings are displayed for *breakpoints* you add either in the main XQuery (which you can open locally or from the server) or for *breakpoints* you add in any XQuery that is opened from the connection that participates in the debugging session. For more information, see *Using Breakpoints for Debugging Queries that Import Modules with MarkLogic* on page 1313.

Remote Debugging with MarkLogic

Oxygen XML Editor allows you to debug remote applications that use XQuery (for example, web applications that trigger XQuery executions). Oxygen XML Editor connects to a MarkLogic server, shows you the running XQuery scripts and allows you to debug them. You can even pause the scripts so that you can start the debugging queries in the exact context of the application. You can also switch a server to debug mode to intercept all XQuery scripts.

Oxygen XML Editor also supports collaborative debugging. This feature allows multiple users to participate in the same debugging session. You can start a debugging session and at a certain point, another user can continue it.

Important: When using the remote debugging feature, the HTTP and the XDBC servers involved in the debugging session must have the same module configuration.

For more information about the XQuery debugger for MarkLogic, watch our video demonstration:

Related Information:

MarkLogic Development in Oxygen XML Editor on page 1311
Configuring a MarkLogic Database Connection on page 1310

Using Breakpoints for Debugging Queries that Import Modules with MarkLogic

When debugging queries that imports modules stored in the database, it is recommended to place *breakpoints* in the modules. When starting a new debugging session, make sure that the modules that you will debug are already opened in the editor. This is necessary so that the *breakpoints* in all the modules will be considered. Also, make sure that there are no other opened modules that are not involved in the current debugging session.

To place *breakpoints* in the modules, use the following procedure:

1. In the ***Data Source Explorer*** *view*, open all the modules from the **Modules** container of the *XDBC application server* that performs the debugging.
2. *Set breakpoints* in the module as needed.
3. *Continue debugging* the query.

If you get a warning that the *breakpoints* failed to initialize, try the following solutions:

- Check the ***Breakpoints*** *view* and make sure there are no older *breakpoints* (set on resources that are not part of the current debugging context).
- Make sure you open the modules from the context of the application server that does the debugging and place *breakpoints* there.

MarkLogic Database Connections on page 1309
MarkLogic Development in Oxygen XML Editor on page 1311

Peculiarities and Limitations of the MarkLogic Debugger

MarkLogic debugger has the following peculiarities and limitations:

- Debugging support is only available for MarkLogic server versions 4.0 or newer.
- For MarkLogic server versions 4.0 or newer, there are three XQuery syntaxes that are supported: *'0.9-ml' (inherited from MarkLogic 3.2)*, *'1.0-ml'*, and *'1.0'*.
- All declared variables are presented as strings. The **Value** column of the **Variables** view contains the expression from the variable declaration. It can be evaluated by copying the expression with the **Copy value** action from the contextual menu of *the* ***Variables*** *view* and pasting it in *the* ***XWatch*** *view*.
- There is no support for *output to source mapping*.
- There is no support for *showing the trace*.
- You can only set *breakpoints* in imported modules in one of the following cases:
  - When you open the module from the context of the application server involved in the debugging, using the ***Data Source Explorer*** *view*.
  - When the debugger automatically opens the modules in the Editor.
- No *breakpoints* are set in modules from the same server that are not involved in the current debugging session.
- No support for *profiling* when an XQuery transformation is executed in the debugger.

Debugging with Berkeley DB XML

The Berkeley DB XML database added a debugging interface starting with version 2.5. The current version is supported in the Oxygen XML Editor XQuery Debugger. *The same restrictions and peculiarities* apply for the Berkeley debugger as for the MarkLogic debugger.

Content Management System (CMS) Integration

This chapter explains how you can use Oxygen XML Editor with Documentum CMS and Microsoft SharePoint. You can use the *plugin support* to develop your own integration with other content management systems..

All the major CMS vendors that are listed in the *CMS Solution Partners section of our website* also provide CMS integration with Oxygen XML Editor.

Related Information:

General Configuration of an Oxygen XML Editor Plugin on page 1555
Working with Databases on page 1283

Integration with Documentum (CMS) (deprecated)

Important: Starting with version 17.0, the support for Documentum (CMS) is deprecated and will no longer be actively maintained.

Oxygen XML Editor provides support for browsing and managing Documentum (CMS) connections in the ***Data Source Explorer** view*. You can easily create new resources on the repository, copy and move them using contextual actions or the drag and drop support, or edit and transform the documents in the editor.

Oxygen XML Editor supports Documentum (CMS) version 6.5 and 6.6 with **Documentum Foundation Services 6.5 or 6.6** installed.

Attention: It is recommended to use the latest 1.6.x Java version. It is possible that the Documentum (CMS) support will not work properly if you use other Java versions.

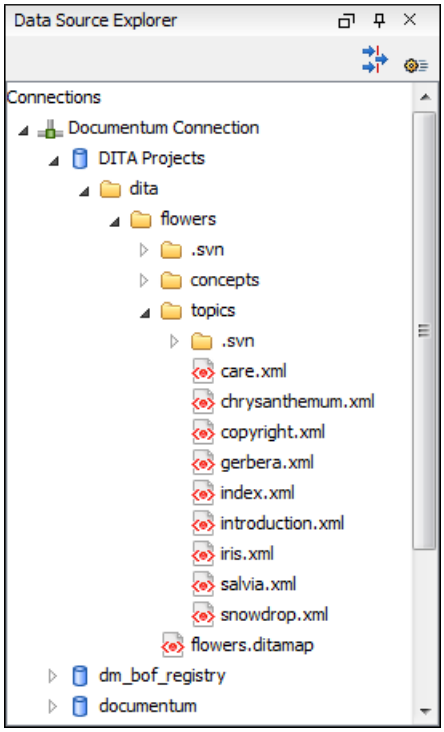

Figure 669: Documentum (CMS) Connection

Configuring a Documentum (CMS) Database Connection

Follow this procedure to configure the support for a Documentum (CMS) database:

1. *Configure Documentum CMS Data Source drivers*.
2. *Configure a Documentum CMS Connection*.
3. To view your connection, go to the ***Data Source Explorer** view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu) or switch to the **Database** *perspective*.

How to Configure Documentum (CMS) Data Source Drivers

Available in the Enterprise edition only.

To configure a Documentum (CMS) data source you need the Documentum Foundation Services Software Development Kit (DFS SDK) corresponding to your server version. The DFS SDK can be found in the Documentum (CMS) server installation kit or it can be downloaded from *EMC Community Network*.

Note: The DFS SDK can be found in the form of an archive named for Documentum (CMS) 6.5 (for example, *emc-dfs-sdk-6.5.zip*).

To configure a data source for Documentum (CMS), follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. In the **Data Sources** panel click the **New** button.
3. Enter a unique name for the data source.
4. Select **Documentum (CMS)** from the driver type combo box.
5. Press the **Choose DFS SDK Folder** button.

6. Select the folder where you have unpacked the DFS SDK archive file.

   If you have indicated the correct folder the following Java libraries (*JAR* files) will be added to the list (some variation of the library names is possible in future versions of the DFS SDK):

   - `lib/java/emc-bpm-services-remote.jar`
   - `lib/java/emc-ci-services-remote.jar`
   - `lib/java/emc-collaboration-services-remote.jar`
   - `lib/java/emc-dfs-rt-remote.jar`
   - `lib/java/emc-dfs-services-remote.jar`
   - `lib/java/emc-dfs-tools.jar`
   - `lib/java/emc-search-services-remote.jar`
   - `lib/java/ucf/client/ucf-installer.jar`
   - `lib/java/commons/*.jar` (multiple *JAR* files)
   - `lib/java/jaxws/*.jar` (multiple *JAR* files)
   - `lib/java/utils/*.jar` (multiple *JAR* files)

   Note: If for some reason the *JAR* files are not found, you can add them manually by using the **Add Files** and **Add Recursively** buttons and navigating to the `lib/java` folder from the DFS SDK.
7. Click the **OK** button to finish the data source configuration.
8. Continue on to *configure your Documentum connection*.

How to Configure a Documentum (CMS) Connection

Available in the Enterprise edition only.

To configure a connection for a Documentum (CMS) server, follow these steps:

1. *Open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **Data Sources**.
2. In the **Connections** panel click the **New** button.
3. Enter a unique name for the connection.
4. Select one of the previously configured Documentum (CMS) data sources in the **Data Source** combo box.
5. Fill-in the connection details:
   - **URL** - The URL to the Documentum (CMS) server: `http://<hostname>:<port>`
   - **User** - The user name to access the Documentum (CMS) repository.
   - **Password** - The password to access the Documentum (CMS) repository.
   - **Repository** - The name of the repository to log into.
6. Click the **OK** button to finish the configuration of the connection.

Known Issues with Documentum (CMS)

The following are known issues with the Documentum (CMS):

- There is a known problem in the UCF Client implementation for Mac OS X from Documentum 6.5 that prevents you from viewing or editing XML documents from the repository on Mac OS X. The UCF Client is the component responsible for file transfer between the repository and the local machine. This component is deployed automatically from the server. Documentum 6.6 does not exhibit this problem.

  Note: This issue was reproduced with Documentum 6.5 SP1. In Documentum 6.6 this is no longer reproducing.
- For the Documentum driver to work faster on Linux, you need to specify to the JVM to use a weaker random generator, instead of the very slow native implementation. This can be done by modifying in the Oxygen XML Editor startup scripts (or in the `*.vmoptions` file) the system property:

  ```
  -Djava.security.egd=file:/dev/./urandom
  ```

Documentum (CMS) Contextual Menu Actions

While browsing Documentum (CMS) connections in the ***Data Source Explorer** view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

New Cabinet

Creates a new cabinet in the repository. The cabinet properties are:

- **Type** - The type of the new cabinet (default is **dm_cabinet**).
- **Name** - The name of the new cabinet.
- **Title** - The title property of the cabinet.
- **Subject** - The subject property of the cabinet.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Container (Cabinet) Level Nodes

New Folder

Creates a new folder in the current cabinet / folder. The folder properties are the following:

- **Path** - Shows the path where the new folder will be created.
- **Type** - The type of the new folder (default is **dm_folder**).
- **Name** - The name of the new folder.
- **Title** - The title property of the folder.
- **Subject** - The subject property of the folder.

New Document

Creates a new document in the current cabinet / folder. The document properties are the following:

- **Path** - Shows the path where the new document will be created.
- **Name** - The name of the new document.
- **Type** - The type of the new document (default is **dm_document**).
- **Format** - The document content type format.

Import

Imports local files / folders in the selected cabinet / folder of the repository. Actions available when performing an import:

- **Add Files** - Opens a file browse dialog box and allows you to select files to add to the list.
- **Add Folders** - Opens a folder browse dialog box that allows you to select folders to add to the list. The subfolders will be added recursively.
- **Edit** - Opens a dialog box where you can change the properties of the selected file / folder from the list.
- **Remove** - Removes the selected files / folders from the list.

Export

Allows you to export the folder on the remote connection to a local folder.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Edit

Checks out and opens the selected resource in the editor (if it is not already checked out).

Edit with

Checks out and opens the selected resource in the specified editor or tool (if it is not already checked out).

Open (Read-only)

Opens the selected resource in the editor. The resources are marked as read-only in the editor using a lock icon on the file tab. If you want to edit those resources, select the ***Can edit read only files*** *option* in the **Editor** preferences page.

Open with

Opens the selected resource in the specified editor or tool.

Check Out

Checks out the selected resource from the repository. The action is not available if the resource is already checked out.

Check In

Opens the **Check In** dialog box that allows you to check in the selected resource (commits changes) into the repository and configure some properties for the resource. The action is only available if the resource is checked out.

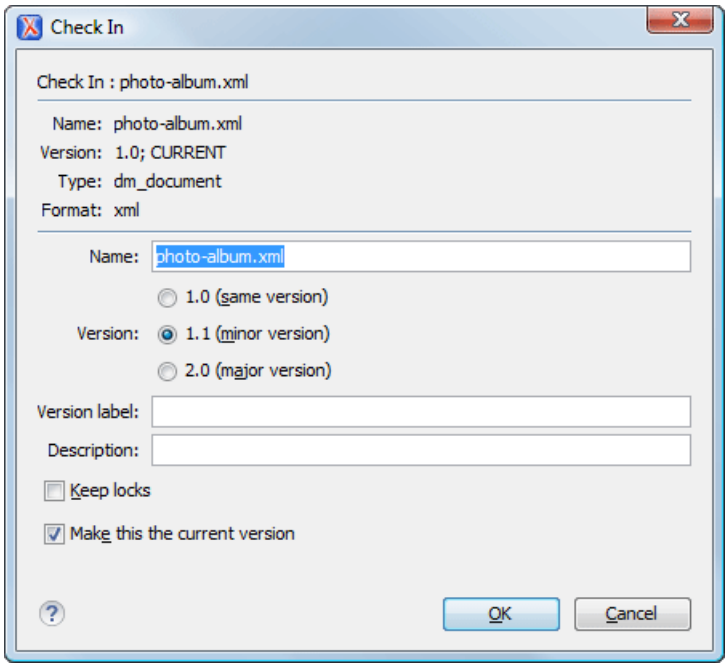

Figure 670: Check In Dialog Box

The following resource properties can be configured in this dialog box:

- **Name** - The resource name in the repository.

- **Version** - Allows you to choose what version the resource will have after being checked in.
- **Version label** - The label of the updated version.
- **Description** - An optional description of the resource.
- **Keep Locks** - When this option is selected, the updated resource is checked in to the repository but it also keeps it locked.
- **Make this the current version** - Makes the updated resource the current version (will have the *CURRENT* version label).

Cancel Checkout

Cancels the checkout process and loses all modifications since the checkout. Action is only available if the resource is checked out.

Export

Allows you to export the folder on the remote connection to a local folder.

Copy

Copies the selected resource to another location in the tree. This action is not available on virtual document descendants. This action can also be performed with drag and drop while holding the **Ctrl (Meta on OS X)** key pressed.

Move

Moves the selected resource to another location in the tree. Action is not available on virtual document descendants and on checked out resources. This action can also be performed with drag and drop.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Rename

Renames the current resource

 **Delete**

Deletes the current container.

Add Relationship

Adds a new relationship for the selected resource. This action can also be performed with drag and drop between resources.

Convert to Virtual Document

Allows you to convert a simple document to a virtual document. Action is available only if the resource is a simple document.

Convert to Simple Document

Allows you to convert a virtual document to a simple document. Action is available only if the resource is a virtual document with no descendants.

 **Refresh**

Performs a refresh on the selected node.

 **Properties**

Shows various properties of the current container.

 **Find/Replace in Files**

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

Integration with Microsoft SharePoint

Oxygen XML Editor provides support for browsing and managing SharePoint connections in the ***Data Source Explorer*** *view*. You can easily create new resources on the repository, copy and move them using contextual actions or the drag and drop support, or edit and transform the documents in the editor.

Note: You can access documents stored on SharePoint Online for Office 365 sites that use either **Cloud identity (default)** or **Federated identity (ADFS)** as the authentication method.

Restriction: The SharePoint connection is only available in the Enterprise edition of Oxygen XML Editor.

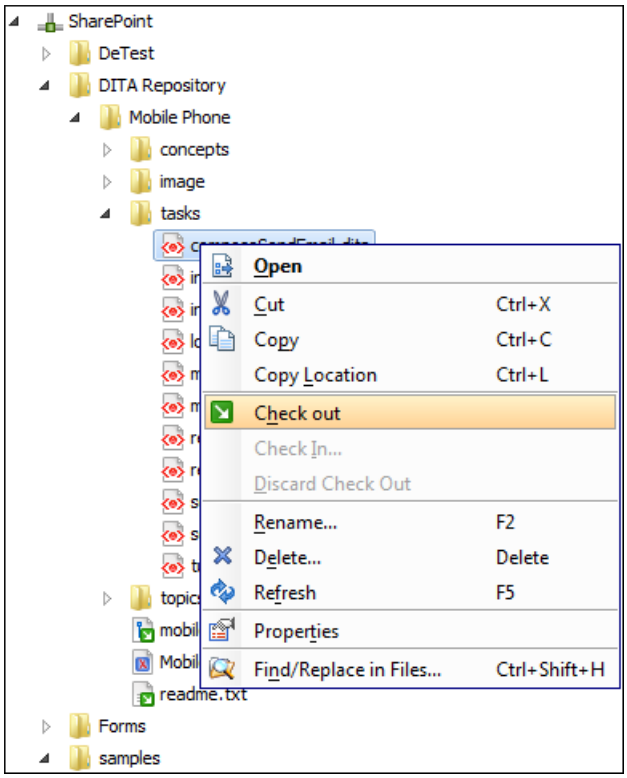

Figure 671: SharePoint Connection

Working with Databases on page 1283

How to Configure a SharePoint Connection

By default, Oxygen XML Editor contains built-in data source drivers for **SharePoint**. Use this data source to create a connection to a SharePoint server that will be available in the ***Data Source Explorer*** *view*.

To configure a SharePoint connection, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Data Sources**.
2. In the **Connections** panel click the **New** button.
3. Enter a unique name for the connection.
4. Select SharePoint in the **Data Source** combo box.
5. Fill-in the connection details:
   a) Set the URL to the SharePoint repository in the field **SharePoint URL**.
   b) Set the server domain in the **Domain** field. If you are using a SharePoint 365 account, leave this field empty.
   c) Set the user name to access the SharePoint repository in the **User** field.
   d) Set the password to access the SharePoint repository in the **Password** field.
6. To view your connection, go to the ***SharePoint Browser*** *view* (if the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu).

For more information about connecting to repository located on a SharePoint server, watch our video demonstration:

SharePoint Browser View

The **SharePoint Browser** view allows you to connect to a SharePoint repository and perform SharePoint-specific actions on the available resources. To display this view, go to **Window** > **Show View** > **SharePoint Browser**.

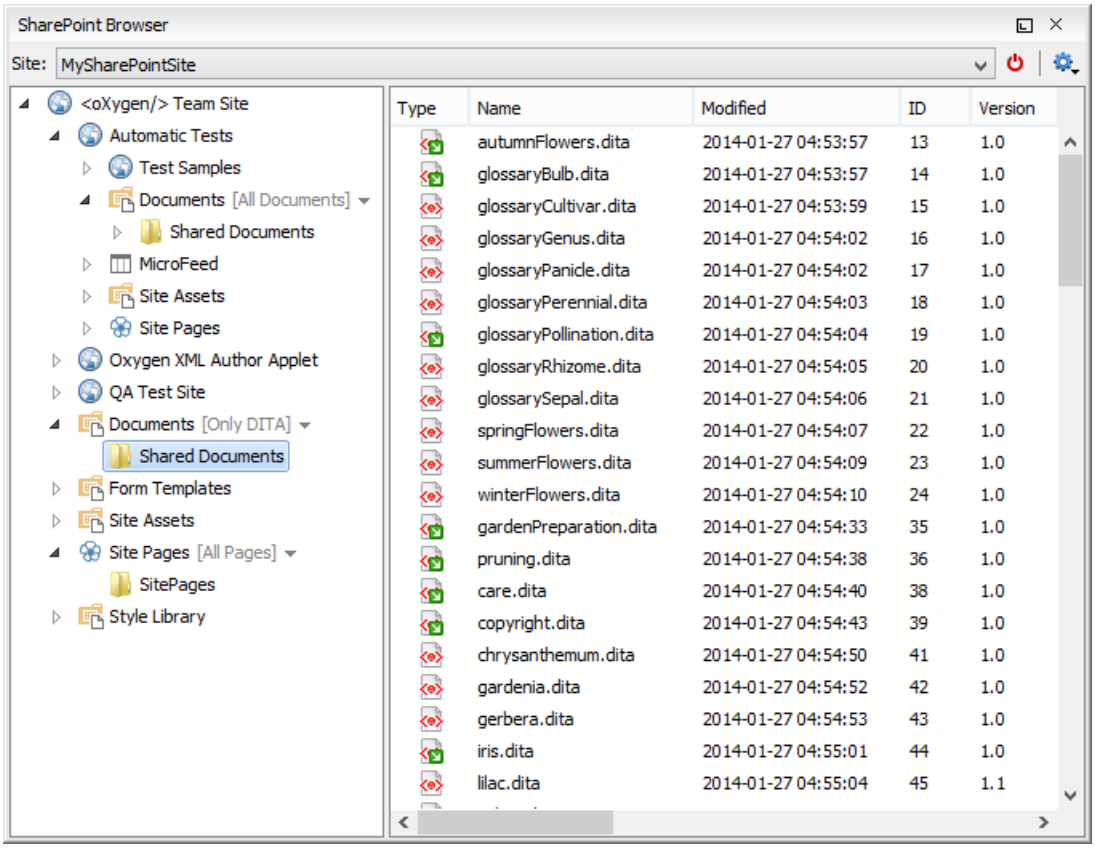

Figure 672: SharePoint Browser View

The view is split in several functional areas:

Connection Area

The following controls are available:

- The **Site** combo box allows you to select and connect to an already *defined SharePoint connection*.
- The **Disconnect** action terminates the current connection.
- The **Settings** drop-down menu contains actions that help you to quickly define a new connection or manage the existing ones from the **Data Source** options page: **New SharePoint Connection** and **Configure Database Sources**. Also, here you can choose one of the predefined view layouts.

SharePoint Site Navigation Area

If there is no connection selected in the **Site** combo box, this area is left blank and promotes the actions that allow you to quickly add SharePoint connections. Otherwise, the navigation area presents the SharePoint site structure in a tree-like fashion with various node types (such as *sites*, *libraries*, and *folders*).

Depending on the type of node, a contextual menu offers customized actions that can be performed on that node. The contextual menu of a folder allows you to create new folders and documents, import folders and files, and to rename and delete the folder.

Note: The rename and delete actions are not available for library root folders (folders located at first level in a SharePoint library).

Each library node displays a drop-down menu next to its name where you can select what you want to display for the current library node. This functionality is also available on the contextual menu of the node.

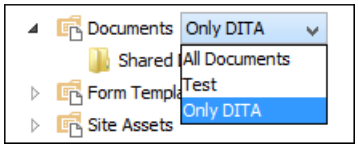

Figure 673: Drop-Down Menu to Select Which Items to Display

Folder Content Area

The content of a folder is displayed in a tabular form, where each row represents the properties of a folder or document. The list of columns and the way the documents and folders are organized depends on the currently selected view of the parent library.

Table 70: Contextual Menu Actions for the Folder Area

Action	Description	Available for	
		folders	documents
Open	Displays the content of the currently selected folder. Opens the current document for editing.	✓	✓
Rename	Renames the current node on server.	✓	✓
Import	Import files or folders into the currently selected folder.	✓	✓
Delete	Deletes the current node from the server.	✓	✓
Copy Location	Copies to clipboard the URL of the current node.	✓	✓
Check Out	Reserves the current document for your use so that other users cannot change it while you are editing it.		✓
Check In	Commits on the server the changes you made to the document, so that other users can see them. It also makes the document available for editing to other users.		✓
Discard Check Out	Discards the previous checkout operation, making the file available for editing to other users.		✓
Refresh	Queries the server to refresh the available properties of the current node.	✓	✓
Drag and Drop	You can drag documents from the **SharePoint Browser** view and drop them in the main editor area to open them with ease.		✓

You can filter and sort the displayed items. To display the available filters of a column, click the filter widget located on the column header. You can apply multiple filters at the same time.

Note: A column can be filtered or sorted only if it was configured this way on the server side.

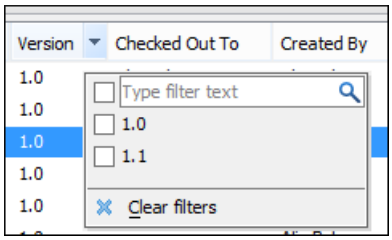

Figure 674: Column Filter

How to Configure a SharePoint Connection on page 1341

SharePoint Contextual Menu Actions

While browsing SharePoint connections in the ***Data Source Explorer*** *view*, the various nodes include the following contextual menu actions:

Connection Level Nodes

Configure Database Sources

Opens the ***Data Sources*** *preferences page* where you can configure both data sources and connections.

Disconnect

Stops the connection.

New Folder

Creates a new folder on the connection.

Import Files

Allows you to add a new file on the connection, in the current folder.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Folder Level Nodes

New File

Creates a new file on the connection, in the current folder.

New Folder

Creates a new folder on the connection.

Import Folders

Imports folders on the server.

Import Files

Allows you to add a new file on the connection, in the current folder.

Export

Allows you to export the folder on the remote connection to a local folder.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Paste

Pastes the copied selection.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Resource Level Nodes

Open

Opens the selected resource in the editor.

Open in System Application

When you use this action, Oxygen XML Editor downloads the selected resource to a local temporary folder and opens the selected resource in the system application that is currently set as the default application associated with that type of resource. You can then edit the resource, save it, and when you switch the focus back to the **Data Source Explorer** view, Oxygen XML Editor will detect that there was a change and will ask if you want to upload the edited resource to the server.

Cut

Removes the current selection and places it in the clipboard.

Copy

Copies the current selection into the clipboard.

Copy location

Allows you to copy (to the clipboard) an application-specific URL for the resource that can then be used for various actions, such as opening or transforming the resources.

Check Out

Checks out the selected document on the server.

Check In

Checks in the selected document on the server. This action opens the **Check In** dialog box. In this dialog box, the following options are available:

- **Minor Version** - Increments the minor version of the file on the server.
- **Major Version** - Increments the major version of the file on the server.
- **Overwrite** - Overwrites the latest version of the file on the server.
- **Comment** - Allows you to comment on a file that you check in.

Discard Check Out

Discards the previous checkout operation, making the file available for editing to other users.

Rename

Renames the current resource

Delete

Deletes the current container.

Refresh

Performs a refresh on the selected node.

Properties

Shows various properties of the current container.

Find/Replace in Files

Opens the ***Find/Replace in Files*** *dialog box* that allows you to find and replace text in multiple files from the connection.

Compare

Compares two selected resources using the ***Compare Files*** *tool*.

Importing Data

13

Topics:

- *Import from Text Files*
- *Import from MS Excel Files*
- *Import Database Data as an XML Document*
- *Import from HTML Files*
- *Import Content Dynamically*

Computer systems and databases contain data in incompatible formats and exchanging data between these systems can be very time consuming. Converting the data to XML can greatly reduce the complexity and create data that can be read by various types of applications.

Oxygen XML Editor offers support for importing text files, MS Excel files, Database Data, and HTML files into XML documents. The XML documents can be further converted into other formats using the *Transform features*.

Import from Text Files

To import a text file into an XML file, follow these steps:

1. Go to **File** > **Import** > **Text File**.
   A **Select text file** dialog box is displayed.
2. Select the URL of the text file.
3. Select the encoding of the text file.
4. Click the **Next** button.
   The **Import Criteria** dialog box is displayed.

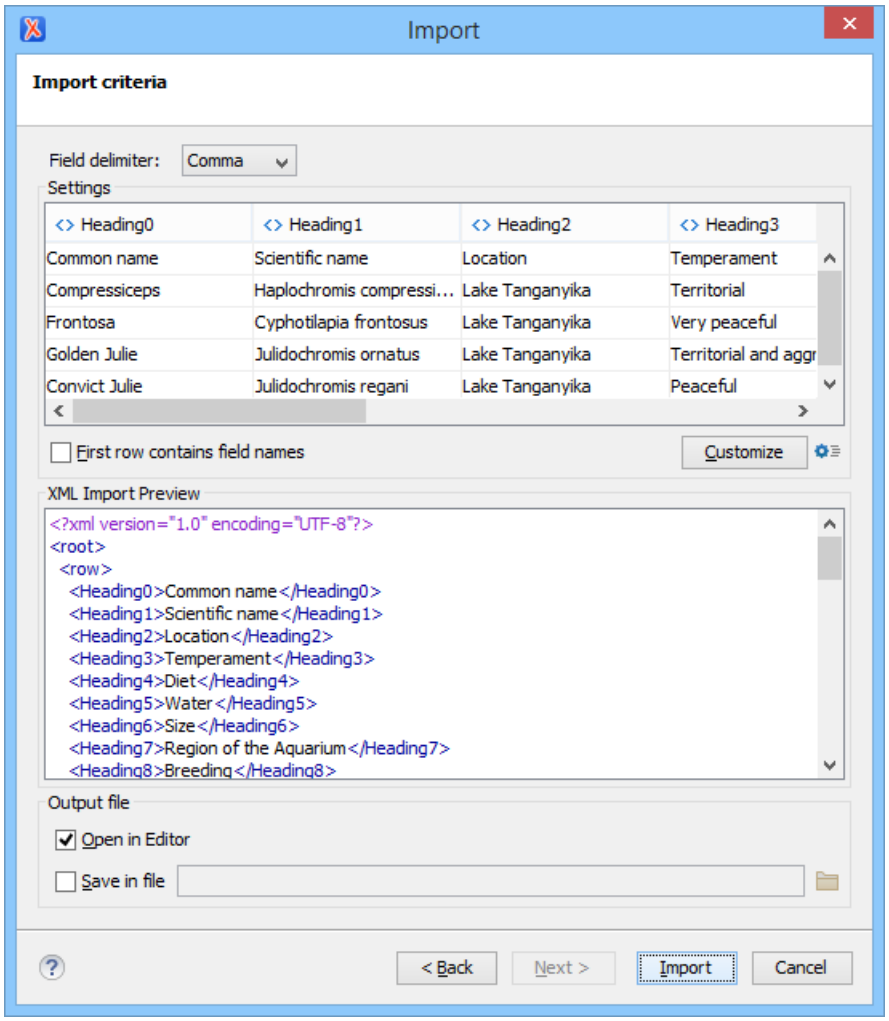

Figure 675: Import Criteria Dialog Box

5. Configure the settings for the conversion.
   a) Select the **Field delimiter** for the import settings. You can choose between the following: `Comma`, `Semicolon`, `Tab`, `Space`, or `Pipe`.
   b) The **Import settings** section presents the input data in a tabular form. By default, all data items are converted to element content (‹› symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (= symbol). Clicking a second time causes the column data to be ignored (× symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.
   c) **First row contains field names** - If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is interpreted as containing the field names. The changes are also visible in the preview panel.
   d) **Customize** - This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: `ELEMENT`, `ATTRIBUTE`, or `SKIPPED`.
   e) **Import Settings** - Clicking this button opens the ***Import*** *preferences page* that allows you to configure more import options.
   f) The **XML Import Preview** panel contains an example of what the generated XML document looks like.
   g) **Open in editor** - If selected, the new XML document created from the imported text file is opened in the editor.
   h) **Save in file** - If selected, the new XML document is saved in the specified path.

6. Click **Import** to generate the XML document.

Import from MS Excel Files

Oxygen XML Editor provides several methods for importing MS Excel files into an XML file. The first method is to use the Oxygen XML Editor ***Smart Paste*** *mechanism* by simply copying data from Excel and pasting it into a document in **Author** mode (note that this is only supported in DITA, DocBook, TEI, JATS, and XHTML documents). You can also copy data from Excel and paste it into inserted cells in **Grid** mode, but this is a more manual process. If you want to import an entire Excel file, Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

Smart Paste Method in Author Mode

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the Excel spreadsheet in your office application, copy its content, and simply paste it into your document in **Author** mode.

The Oxygen XML Editor ***Smart Paste*** *mechanism* will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

Grid Mode Method

The **Grid** mode in Oxygen XML Editor displays all content in an XML document as a structured grid of nested tables and you can work with the cells in those tables much like you would with any spreadsheet application. When importing Excel data into **Grid** mode, you first need to insert new cells in the particular nested table and then you can paste data from Excel the same as you would in any table or spreadsheet.

1. Copy the particular cells from your Excel spreadsheet that you want to import into an XML file.
2. Switch to **Grid** mode in Oxygen XML Editor.
3. Expand the particular nodes and locate the nested table where you want to insert the copied cells.
4. Right-click a particular row or column where you want to insert the data and select **Insert row** or **Insert column**, depending on the structure of the copied cells.
5. Paste the copied cells from the clipboard into the newly inserted cells in **Grid** mode.
6. You may need to make some manual adjustments. For example, if the selection of copied cells contained an empty cell, Oxygen XML Editor might ignore that cell.

Import Wizard Method

By default, this method supports importing Excel 97/2000/XP/2003 formats out-of-the-box. To import spreadsheet data from Excel 2007 or newer, additional libraries are needed before using this procedure. See *Import Data from MS Excel 2007 or Newer* on page 1351 for instructions on adding more libraries.

To use the **Import** wizard to import an Excel file into an XML file, follow these steps:

1. Go to **File** > **Import** > **MS Excel file**.
2. Select the URL of the Excel file.

   The sheets of the document you are importing are presented in the **Available Sheets** section of this dialog box.
3. Click the **Next** button to proceed to the next stage of the wizard.

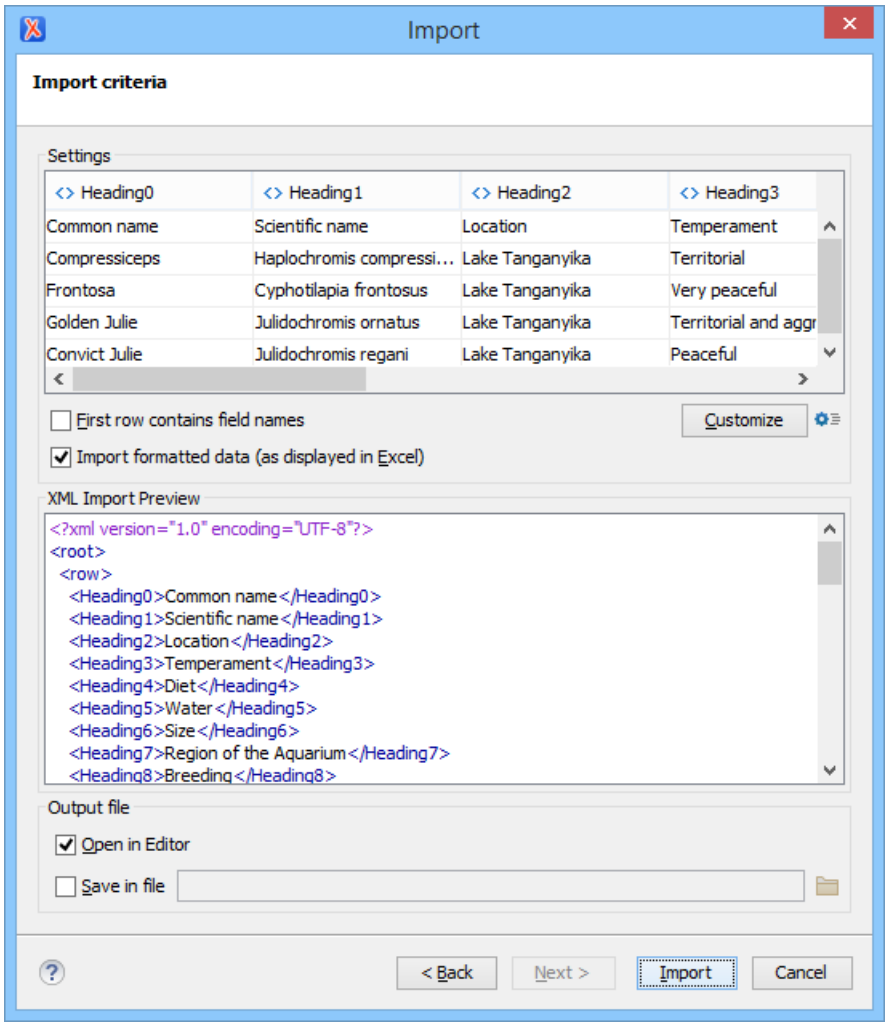

Figure 676: Import Wizard

4. Configure the settings for the conversion. This stage of the wizard offers the following options:

   Import settings section

   Presents the input data in a tabular form. By default, all data items are converted to element content (‹› symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (= symbol). Clicking a second time causes the column data to be ignored (× symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.

   First row contains field names

   If this option is selected, the default column headers are replaced (where such information is available) by the content of the first row. In other words, the first row is interpreted as containing the field names. The changes are also visible in the preview panel.

   Customize

   This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: `ELEMENT`, `ATTRIBUTE`, or `SKIPPED`.

   Import Settings

   Clicking this button opens the ***Import*** *preferences page* that allows you to configure more import options.

Import formatted data (as displayed in Excel)

If this option is selected, the imported data retains the Excel data formatting (such as the representation of numeric values or dates). If deselected, the data formatting is not imported.

XML Import Preview panel

Contains an example of what the generated XML document will look like.

Open in editor

If selected, the new XML document created from the imported file is opened in the editor.

Save in file

If selected, the new XML document is saved in the specified path.

5. Click **Import** to generate the XML document.

For more information about exchanging data between Oxygen XML Editor and spreadsheet applications, watch our video demonstration:

Related Information:

Exporting XML Content to Excel on page 533

Import Data from MS Excel 2007 or Newer

To import spreadsheet data from Excel 2007 or newer (`.xlsx`), Oxygen XML Editor needs additional libraries from the release 3.10 of the Apache POI project.

To add this support, follow this procedure:

1. Go to **Help** > **Install new add-ons** to open an add-on selection dialog box.
2. Enter or paste **http://www.oxygenxml.com/InstData/Addons/default/updateSite.xml** in the **Show add-ons from** field or select it from the drop-down menu.
3. Select **Excel XLSX libraries** plugin and click **Next**.
4. Restart the application.

Result: You can now use the ***Import** wizard* to import data from Excel 2007 or newer.

Alternate Method to Manually Add the Libraries

To manually add the libraries, follow these steps:

1. Download version 3.10 of the Apache POI project from *http://archive.apache.org/dist/poi/release/bin/*. The specific ZIP file that you need is: `poi-bin-3.10-FINAL-20140208.zip`.
2. Unpack `poi-bin-3.10-FINAL-20140208.zip`.
3. Copy the following `.jar` files in the `lib` directory of the installation folder of Oxygen XML Editor :
   - `dom4j-1.6.1.jar`
   - `poi-ooxml-3.10-FINAL-20140208.jar`
   - `poi-ooxml-schemas-3.10-FINAL-20140208.jar`
   - `xmlbeans-2.3.0.jar`

Result: You can now use the ***Import** wizard* to import data from Excel 2007 or newer.

Related Information:

Exporting XML Content to Excel on page 533

Import Database Data as an XML Document

To import the data from a relational database table as an XML document, follow these steps:

1. Go to **File** > **Import** > **Database Data** to start the **Import** wizard.

   This opens a **Select database table** dialog box that lists all the defined database connections:

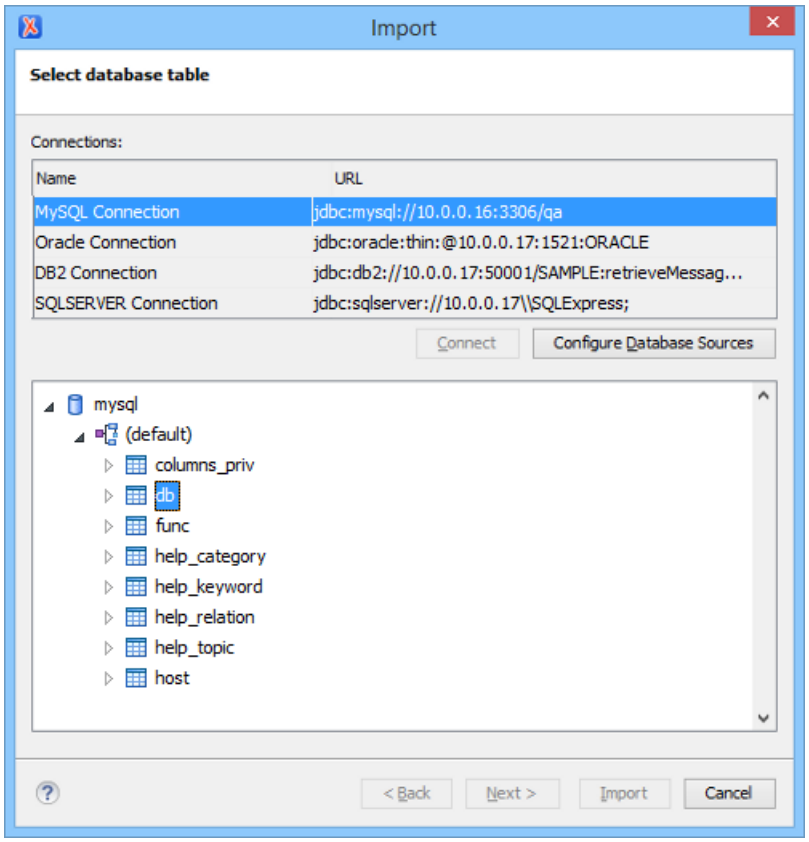

Figure 677: Select Database Table Dialog Box

2. Select the connection to the database that contains the appropriate data.

   Only connections configured in relational data sources can be used to import data.
3. If you want to edit, delete, or add a data source or connection, click the **Configure Database Sources** button. The **Preferences**/**Data Sources** option page is opened.
4. Click **Connect**.
5. In the list of sources, expand a schema and choose the required table.
6. Click the **Next** button.

   The **Import Criteria** dialog box is opened with a default query string in the **SQL Query** pane.

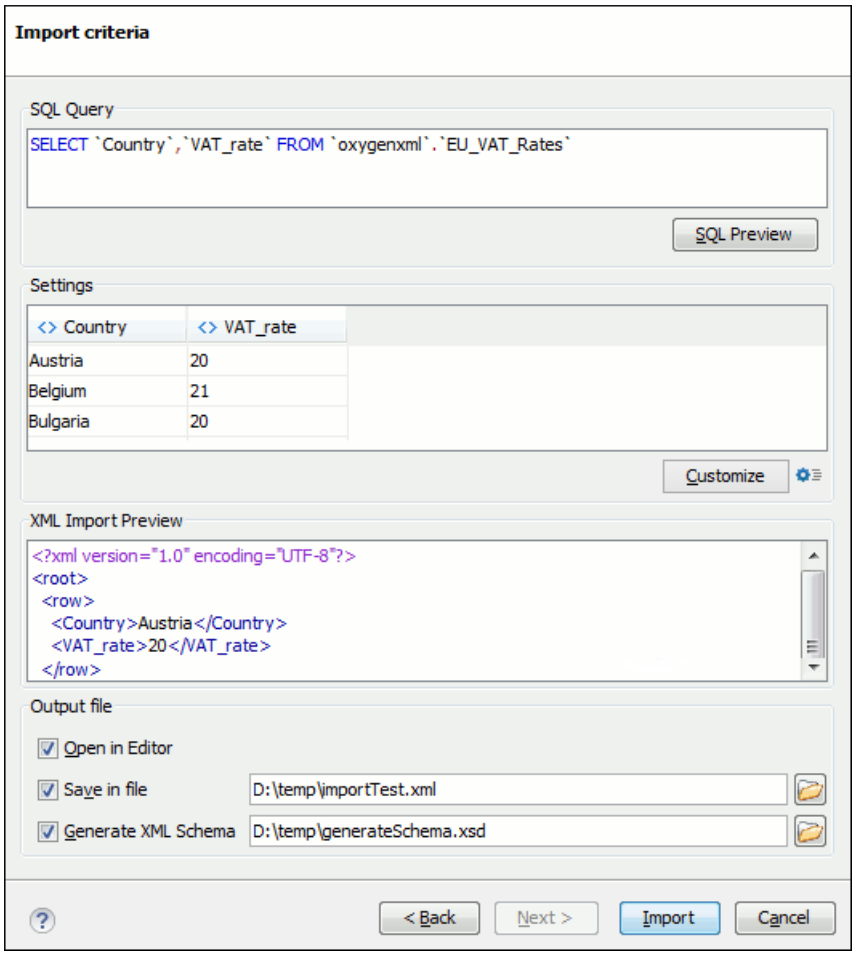

Figure 678: Import from Database Criteria Dialog Box

7. Configure the settings for the conversion.
   a) **SQL Preview** - If this button is pressed, the **Settings** pane displays the labels that are used in the XML document and the first five lines from the database. By default, all data items are converted to element content (<> symbol), but this can be overridden by clicking the individual column headers. Clicking a column header once causes the data from this column to be converted to attribute values (= symbol). Clicking a second time causes the column data to be ignored (× symbol) when generating the XML file. You can cycle through these three options by continuing to click the column header.
   b) **Customize** - This button opens a **Presentation Names** dialog box that allows you to edit the name, XML name, and conversion criterion for the root and row elements. The XML names can be edited by double-clicking the desired item and entering the label. The conversion criteria can also be modified by selecting one of the following option in the drop-down menu: `ELEMENT`, `ATTRIBUTE`, or `SKIPPED`.
   c) **Import Settings** - Clicking this button opens the ***Import*** *preferences page* that allows you to configure more import options.
   d) The **XML Import Preview** panel contains an example of what the generated XML document looks like.
   e) **Open in editor** - If selected, the new XML document created from the imported file is opened in the editor.
   f) **Save in file** - If selected, the new XML document is saved in the specified path.
   g) **Generate XML Schema** - Allows you to specify the path of the generated XML Schema file.
8. Click **Import** to generate the XML document.

Import from HTML Files

Oxygen XML Editor offers two methods for importing HTML files into an XML document. The first method is to simply copy data from an HTML document and paste it into a document in **Author** mode, but this is only

supported in DITA, DocBook, TEI, JATS, and XHTML documents. Oxygen XML Editor also offers a configurable import wizard that works with any type of XML document.

Smart Paste Method

If you are importing data into DITA, DocBook, TEI, JATS, or XHTML documents, you can open the HTML document in your web browser, copy its content, and paste it into your document in **Author** mode.

The Oxygen XML Editor ***Smart Paste*** *mechanism* will convert the pasted content to the equivalent XML markup and considers various pasting solutions to keep the resulting document valid, while preserving the original text styling (such as bold, italics, underline) and formatting (such as lists, tables, paragraphs).

Import Wizard Method

To use the **Import** wizard to import from HTML files, follow these steps:

1. Go to **File** > **Import** > **HTML File**. The **Import HTML** wizard is displayed.
2. Enter the URL of the HTML document.
3. Select the type of the resulting XHTML document:
   - XHTML5
   - XHTML 1.0 Transitional
   - XHTML 1.0 Strict
4. Click the **OK** button.

Result: The resulting document is an XHTML file containing a DOCTYPE declaration that references the XHTML DTD definition on the Web. The parsed content of the imported file is transformed to XHTML5, XHTML Transitional, or XHTML Strict depending on the option you chose.

Import Content Dynamically

Along with the built-in support for various useful URL protocols (such as HTTP or FTP), Oxygen XML Editor also provides special support for a *convert* protocol that can be used to chain predefined processors to dynamically import content from various sources.

A *dynamic conversion URL* chains various processors that can be applied, in sequence, on a target resource and has the following general syntax:

```
convert:/processor=xslt;ss=urn:processors:excel2d.xsl/processor=excel!/
urn:files:sample.xls
```

The previous example first applies a processor (`excel`) on a target identified by the identifier (`urn:files:sample.xls`) and converts the Excel™ resource to XML. The second applied processor (`xslt`) applies an XSLT stylesheet identified using the identifier (`urn:processors:excel2d.xsl`) over the resulting content from the first applied processor. These identifiers are all mapped to real resources on disk via an *XML catalog* that is configured in the application, as in the following example:

```
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
  <rewriteURI uriStartString="urn:files:" rewritePrefix="./resources/"/>
  <rewriteURI uriStartString="urn:processors:" rewritePrefix="./processors/"/>
</catalog>
```

The target resource part of the conversion URL must always follow the `!/` pattern. It can be any of the following:

- An absolute URL that points to a resource.
- An identifier that will be resolved to an actual resource via the *XML Catalog* support in the application. In the example above, the **urn:files:sample.xls** target resource is resolved via the *XML catalog*.
- A relative location. This location can only be resolved to an actual resource URL when the application has enough information about the location where the URL is referenced.

  For example, for a *DITA map* with a `topicref` such as:

```
<topicref href="convert:/.../processor=excel!/resources/sample.xls"/>
```

the `resources/sample.xls` path will be resolved relative to the *DITA map* location.

This type of URL can be opened in the application by using the **Open URL** action from the **File** menu. It can also be referenced from existing XML resources via `xi:include` or as a topic reference from a *DITA map*.

A *GitHub* project that contains various dynamic conversion samples for producing DITA content from various sources (and then publishing it) can be found here: *https://github.com/oxygenxml/dita-glass*.

Conversion Processors

A set of predefined conversion processors is provided in Oxygen XML Editor. Each processor has its own parameters that can be set to control the behavior of the conversion process. All parameters that are resolved to resources are passed through the *XML catalog* mapping.

The following predefined conversion processors are included:

- **`xslt` Processor** - Converts an XML input using the Saxon EE XSLT processor. The `ss` parameter indicates the stylesheet resource to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

  ```
  convert:/processor=xslt;ss=urn:processors:convert.xsl;p1=v1!/urn:files:sample.xml
  ```
- **`xquery` Processor** - Converts an XML input using the Saxon EE XQuery processor. The `ss` parameter indicates the XQuery script to be loaded. All other specified parameters will be set as parameters to the XSLT transformation.

  ```
  convert:/processor=xquery;ss=urn:processors:convert.xquery;p1=v1!/
  urn:files:sample.xml
  ```
- **`excel` Processor** - Converts an Excel™ input to an XML format that can later be converted by other piped processors. It has a single parameter `sn`, which indicates the name of the sheet that needs to be converted. If this parameter is missing, the XML will contain the combined content of all sheets included in the Excel™ document.

  ```
  convert:/processor=excel;sn=test!/urn:files:sample.xls
  ```
- **`java` Processor** - Converts an input to another format by applying a specific Java method. The `jars` parameter is a comma-separated list of *JAR* libraries, or folders that libraries will be loaded from. The `ccn` parameter is the fully qualified name of the conversion class that will be instantiated. The conversion class needs to have a method with the following signature:

  ```
   public void convert(String systemID, String originalSourceSystemID,
  InputStream is, OutputStream os, LinkedHashMap<String, String> properties)
  throws IOException
  ```

  ```
  convert:/processor=java;jars=libs;ccn=test.JavaToXML!/
  urn:files:java/WSEditorBase.java
  ```
- **`js` Processor** - Converts an input to another format by applying a JavaScript method. The `js` parameter indicates the script that will be used. The `fn` parameter is the name of the method that will be called from the script. The method must take a string as an argument and return a string. If any of the parameters are missing, an error is thrown and the conversion stops.

  ```
  convert:/processor=js;js=urn:processors:md.js;fn=convertExternal!/
  urn:files:sample.md
  ```
- **`json` Processor** - Converts a JSON input to XML. It has no parameters.

  ```
  convert:/processor=json!/urn:files:personal.json
  ```
- **`xhtml` Processor** - Converts HTML content to well-formed XHTML. It has no parameters.

  ```
  convert:/processor=xhtml!/urn:files:test.html
  ```
- **`wrap` Processor** - Wraps content in a tag name making it well-formed XML. The `rn` parameter indicates the name of the root tag to use. By default, it is `wrapper`. The `encoding` parameter specifies the encoding that

should be used to read the content. By default, it is UTF8. As an example, this processor can be used if you want to process a comma-separated values file with an XSLT stylesheet to produce XML content. The CSV file is first wrapped as well-formed XML, which is then processed with an `xslt` processor.

```
convert:/processor=wrap!/urn:files:test.csv
```

- **cache Processor** - Caches the converted content obtained from the original document to a temporary file. The cache will be used on subsequent uses of the same URL, thus increasing the speed for the application returning the converted content. If the original URL points to the local disk, the cache will be automatically invalidated when the original file content gets modified. Otherwise, if the original URL points to a remote resource, the cache will need to be invalidated by reloading (**File** > **Reload (F5)**) the URL content that is opened in the editor.

  ```
  convert:/processor=cache/processor=xslt;…..!/urn:files:test.csv
  ```

Reverse Conversion Processors

All processors defined above can also be used for saving content back to the target resource if they are defined in the URL as reverse processors. Reverse processors are evaluated right to left. These reverse processors allow *round-tripping* content to and from the target resource.

As an example, the following URL converts HTML to DITA when the URL is opened using the `h2d.xsl` stylesheet and converts DITA to HTML when the content is saved in the application using the `d2h.xsl` stylesheet.

```
convert:/processor=xslt;ss=h2d.xsl/rprocessor=xslt;ss=d2h.xsl!/
urn:files:sample.html
```

Important: If you are publishing a *DITA map* that has such conversion URL references inside, you need to edit the transformation scenario and set the value of the parameter *fix.external.refs.com.oxygenxml* to **true**. This will instruct Oxygen XML Editor to resolve such references during a special pre-processing stage. Depending on the conversion, you may also require additional libraries to be added using the **Libaries** button in the **Advanced** tab of the transformation scenario.

Debugging XSLT Stylesheets and XQuery Documents 14

Topics:

- *Debugger Layout*
- *Steps in a Typical Debugging Process*
- *Identify the XSLT / XQuery Expression that Generated Particular Output*
- *Using Breakpoints*
- *Performance Profiling of XSLT Stylesheets and XQuery Documents*
- *Debugging XSLT that Call Java Extensions*
- *Supported Processors for XSLT / XQuery Debugging*

Oxygen XML Editor includes a powerful debugging interface that helps you to detect and solve problems with XSLT and XQuery transformations.

XSLT Debugger Perspective

The **XSLT Debugger** *perspective* allows you to detect problems in an XSLT transformation by executing the process step by step. To switch the focus to this *perspective*, select the **XSLT Debugger** button in the top-right corner of the interface or **Window** > **Open perspective** > **XSLT Debugger**.

XQuery Debugger Perspective

The **XQuery Debugger** *perspective* allows you to detect problems in an XQuery transformation process by executing the process step by step in a controlled environment and inspecting the information provided in the special views. To switch the focus to this *perspective*, select the **XQuery Debugger** button in the top-right corner of the interface or **Window** > **Open perspective** > **XQuery Debugger**.

XSLT/XQuery Debugging Overview

The **XSLT Debugger** and **XQuery Debugger** *perspectives* allows you to test and debug XSLT 1.0 / 2.0 / 3.0 stylesheets and XQuery 1.0 / 3.0 documents including complex XPath 2.0 / 3.0 expressions. The interface presents simultaneous views of the source XML document, the XSLT/XQuery document and the result document. As you go step by step through the XSLT/XQuery document the corresponding output is generated step by step, and the corresponding position in the XML file is highlighted. At the same time, special views provide various types of debugging information and events useful to understand the transformation process.

The following set of features allow you to test and solve XSLT/XQuery problems:

- Support for XSLT 1.0 stylesheets (using Saxon 6.5.5 and Xalan XSLT engines), XSLT 2.0 / 3.0 stylesheets and XPath 2.0 / 3.0 expressions that are included in the stylesheets (using Saxon 9.7.0.19 XSLT engine) and XQuery 1.0 / 3.0 (using Saxon 9.7.0.19 XQuery engine).
- Stepping capabilities: step in, step over, step out, run, run to cursor, run to end, pause, stop.
- Output to source mapping between every line of output and the instruction element / source context that generated it.
- *Breakpoints* on both source and XSLT/XQuery documents.
- Call stack on both source and XSLT/XQuery documents.
- Trace history on both source and XSLT/XQuery documents.
- Support for XPath expression evaluation during debugging.
- Step into imported/included stylesheets as well as included source entities.
- Available templates and hits count.

- Variables view.
- Dynamic output generation.

For even more information, watch our video demonstration:

Debugger Layout

The XML and XSL files are displayed in ***Text*** *mode*. The other modes (***Author*** *mode*, ***Grid*** *mode*) are available only in *the* ***Editor*** *perspective*.

The **XSLT/XQuery Debugger** *perspective* contains the following components:

- **Source Document View (XML)** - Displays and allows the editing of XML files (documents).
- **XSLT/XQuery Document View (XSLT/XQuery)** - Displays and allows the editing of XSL files (stylesheets) or XQuery documents.
- **Output View** - Displays the output that results from inputting a document (XML) and a stylesheet (XSL) or XQuery document in the transformer. The transformation result is written dynamically while the transformation is processed (using the ➔ ***Run*** *button on the Control toolbar*). Several actions are available in the contextual menu for this view, including **Find/Replace**, **Copy**, and **Format and Indent**. There are two types of output views: a **Text** view (with XML syntax highlights) and **XHTML** view. For large outputs, the XHTML view can be disabled (see *Debugger Settings*).
- ***Control Toolbar*** - Contains a variety of actions to help you configure and control the debugging process.
- ***Information Views*** - The information views at the bottom of the editor display various types of information to help you understand the transformation process.

Tip: The **Output** view and the various other information views are *dockable* so that you can configure the workspace according to your preferences.

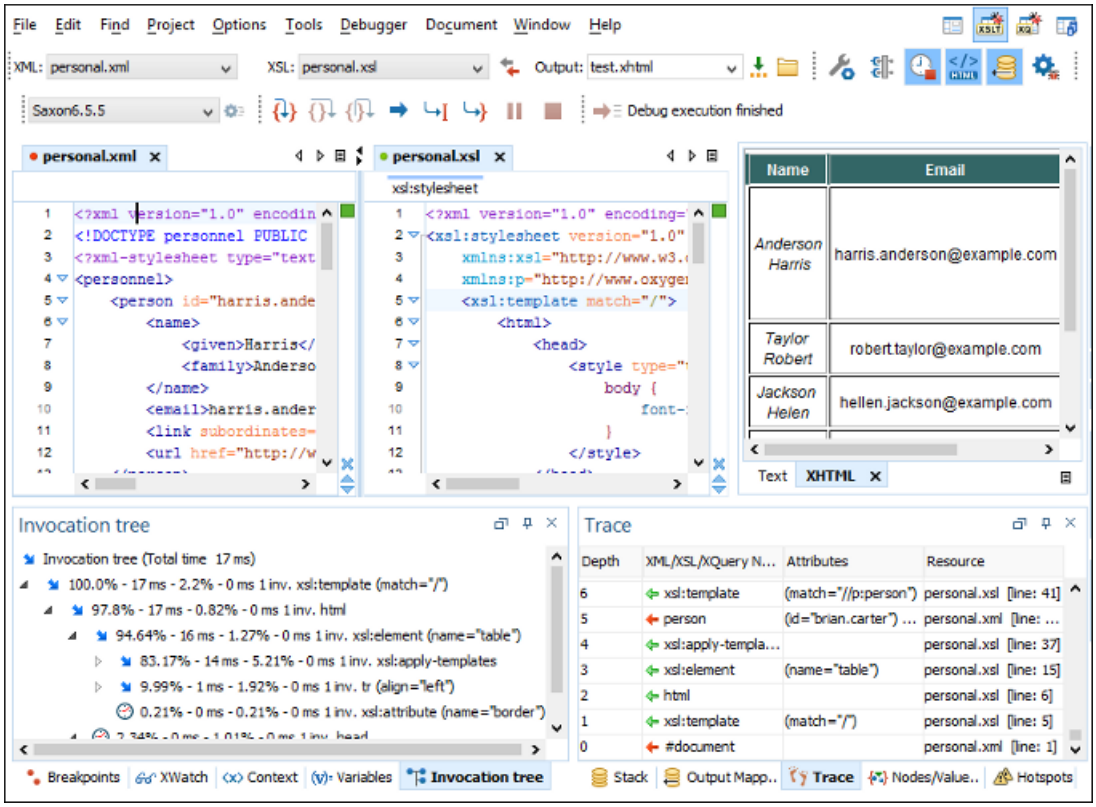

Figure 679: Debugger Interface

XML documents and XSL stylesheets or XQuery documents that were opened in the **Editor** *perspective* are automatically sorted into the first two panes. When multiple files of each type are opened, the individual

documents and stylesheets are separated using the familiar tab management system that you are used to in the **Editor** *perspective*. Selecting a tab brings the document or stylesheet into focus and enables editing without the need to go back to the **Editor** *perspective*.

In Debugger mode, the normal editor toolbar is not available. However, functions are still accessible from the **Document** menu and the contextual menus.

Bookmarks are replaced in the **Debugger** *perspective* by *breakpoints*.

During debugging, the current execution node is highlighted in both document (XML) and XSLT/XQuery views.

Related Information:

Steps in a Typical Debugging Process on page 1371
Identify the XSLT / XQuery Expression that Generated Particular Output on page 1372
Supported Processors for XSLT / XQuery Debugging on page 1379
Performance Profiling of XSLT Stylesheets and XQuery Documents on page 1375

Control Toolbar

The **Control** toolbar contains all the actions that you need to configure and control the debugging process. The following actions are described as they appear in the toolbar from left to right.

Figure 680: Control Toolbar

XML source selector

The current selection represents the source document used as input by the transformation engine. The selection list contains all opened files (XML files being emphasized). This option allows you to use other file types also as source documents. In an XQuery debugging session this selection field can be set to the default value NONE, because usually XQuery documents do not require an input source.

XSL / XQuery selector

The current selection represents the stylesheet or XQuery document to be used by the transformation engine. The selection list contains all opened files (XSLT / XQuery files being emphasized).

Link with editor

When selected, the XML and XSLT/XQuery selectors display the names of the files opened in the central editor panels. This button is toggled off by default.

Output selector

The selection represents the output file specified in the associated transformation scenario. You can specify the path by using the text field, the ***Insert Editor Variables*** button, or the **Browse** button.

Configure parameters

Opens a dialog box that allows you to configure the XSLT / XQuery parameters to be used by the transformation.

Edit extensions

Allows you to add and remove the Java classes and *JARS* used as XSLT extensions.

Turn on/off profiling

Enables / Disables current transformation profiling.

Enable XHTML output

Enables the rendering of the output in the ***XHTML*** *output view* during the transformation process. For performance issues, disable XHTML output when working with very large files. Note that only XHTML conformant documents can be rendered by this view. To view the output result of other formats, such as HTML, save the **Text output** area to a file and use an external browser for viewing.

When starting a debug session from the **Editor** *perspective* by using the **Debug Scenario** action, the state of this toolbar button reflects the state of the **Show as XHTML** output option from the scenario.

Turn on/off output to source mapping

Enables or disables the output to source mapping between every line of output and the instruction element / source context that generated it.

Debugger preferences

Quick link to *Debugger preferences page*.

XSLT / XQuery engine selector

Lists the *processors available for debugging XSLT and XQuery transformations*.

XSLT / XQuery engine advanced options

Advanced options available for Saxon 9.7.0.19.

Step into

Starts the debugging process and runs until the next instruction is encountered.

Step over

Run until the current instruction and its sub-instructions are over. Usually this will advance to the next sibling instruction.

Figure 681: Step over

Step out

Run until the parent of the current instruction is over. Usually this will advance to the next sibling of the parent instruction.

Figure 682: Step out

Run

Starts the debugging process. The execution of the process is paused when a *breakpoint* is encountered or the transformation ends.

Run to cursor

Starts the debugging process and runs until one of the following conditions occur: the line of cursor is reached, a valid *breakpoint* is reached or the execution ends.

Run to end

Runs the transformation until the end, without taking into account enabled *breakpoints*, if any.

Pause

Request to pause the current transformation as soon as possible.

Stop

Request to stop the current transformation without completing its execution.

Show current execution nodes

Reveals the current debugger context showing both the current instruction and the current node in the XML source. Possible displayed states:

- Entering () or leaving () an XML execution node.
- Entering () or leaving () an XSL execution node.
- Entering () or leaving () an XPath execution node.

  Note: When you set a MarkLogic server as a processor, the **Show current execution nodes** button is named **Refresh current session context from server**. Click this button to refresh the information in all the views.

Note: For some of the XSLT processors (Saxon-HE/PE/EE) the debugger could be configured to step into the XPath expressions affecting the behavior of the following debugger actions: **Step into**, **Step over** or **Step Out**.

Related Information:

Advanced Saxon HE/PE/EE XQuery Transformation Options on page 1107

Debugging Information Views

The information views at the bottom of the editor is comprised of two panes that are used to display various types of information used to understand the transformation process. For each information type there is a corresponding tab. While running a transformation, relevant events are displayed in the various information views. This enables the developer to obtain a clear view of the transformation progress. By using the debug controls, developers can easily isolate parts of stylesheet. Therefore, they may be more easily understood and modified.

The information types include the following:

Left side information views

- ***Breakpoints** view*
- ***XWatch** view*
- ***Context** view*
- ***Messages** view* (XSLT only)
- ***Variables** view*
- ***Invocation Tree** view*

Right side information views

- ***Stack** view*
- ***Output Mapping Stack** view*
- ***Trace** view*
- ***Templates** view* (XSLT only)
- ***Nodes/Values Set** view*
- ***Hotspots** view*

Tip: The information views are *dockable* so that you can configure the workspace according to your preferences.

Breakpoints View

The **Breakpoints** view lists all *breakpoints* that are set on opened documents. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu. *Breakpoints can be inserted* in the XML source document or the XSLT/XQuery document in debugging sessions.

Once you insert a *breakpoint*, it is automatically added to the list in the **Breakpoints** view and you can edit its associated *condition*. A *breakpoint* can have an associated break condition that represents an XPath expression evaluated in the current debugger context. In order to be processed, their evaluation result should be a boolean value. A *breakpoint* with an associated condition only stops the execution of the Debugger if the *breakpoint condition* is evaluated as **true**.

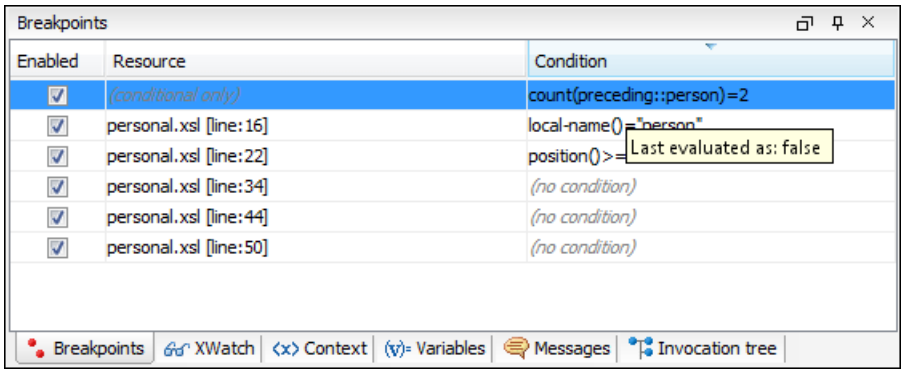

Figure 683: Breakpoints View

The **Breakpoints** view contains the following columns:

- **Enabled** - If selected, the current condition is evaluated and taken into account.
- **Resource** - Resource file and number of the line where the *breakpoint* is set. The Entire path of resource file is available as tooltip.
- **Condition** - XSLT/XQuery expression to be evaluated during debugging. The expression will be evaluated at every debug step.

Clicking a record highlights the *breakpoint* line in the document.

Note: The *breakpoints* list is not deleted at the end of a transformation (it is preserved between debugging sessions).

The following actions are available in the contextual menu of the table:

Go to

Moves the cursor to the source of the *breakpoint*.

Run to Breakpoint

Runs the debugger up to the point of this particular *breakpoint* and ignores the others (regardless of whether they were previously enabled or disabled).

Enable

Enables the *breakpoint*.

Disable

Disables the *breakpoint*. A disabled *breakpoint* will not be evaluated by the Debugger.

Add

Allows you to add a new *breakpoint* and *breakpoint condition*.

Edit

Allows you to edit an existing *breakpoint*.

Remove

Deletes the selected *breakpoint*.

Enable all

Enables all *breakpoints*.

Disable all

Disables all *breakpoints*.

Remove all

Removes all *breakpoints*.

Related Information:

Using Breakpoints on page 1374

Context View

The context node is valid only for XSLT debugging sessions and is a source node corresponding to the XSL expression that is evaluated. It is also called the context of execution. The context node implicitly changes as the processor hits various steps (at the point where XPath expressions are evaluated). This node has the same value as evaluating '.' (dot) XPath expression in ***XWatch** view*. The value of the context node is presented as a tree in the **Context** view. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

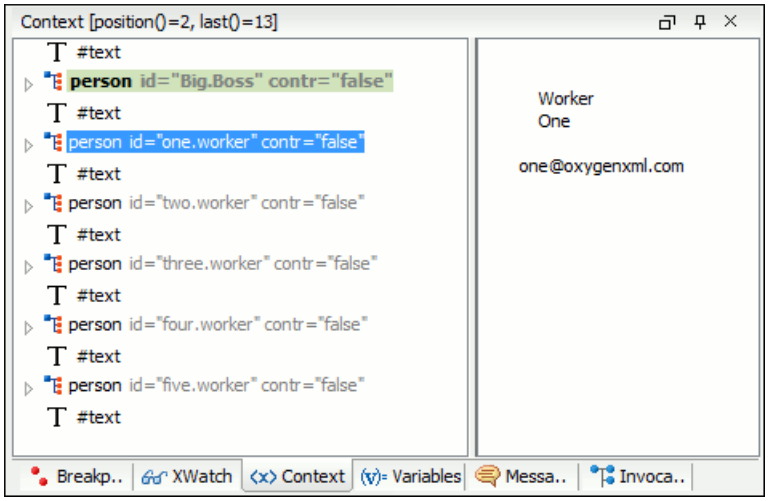

Figure 684: Context node view

The context nodes are presented in a tree-like fashion. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel. The **Context** view also presents the current mode of the XSLT processor if this mode differs from the default one.

The title bar displays the current element index and the number of elements that compose the current context (this information is not available if you choose Xalan or Saxon 6 as processing engine).

XPath Watch (XWatch) View

The **XWatch** view shows XPath expressions evaluated during the debugging process. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Expressions are evaluated dynamically as the processor changes its source context. When you type an XPath expression in the **Expression** column, Oxygen XML Editor supports you with syntax highlight and *content completion assistance*.

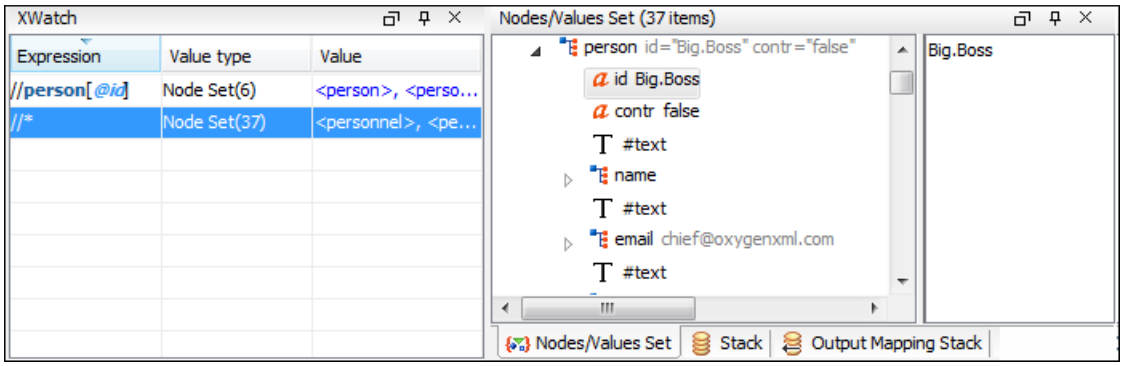

Figure 685: XPath Watch View

Table 71: XWatch columns

Column	Description
Expression	XPath expression to be evaluated (XPath 1.0 or 2.0 / 3.0 compliant).
Value	Result of XPath expression evaluation. Value has a type (see *the possible values* in the section *Variables View*). For *Node Set* results, the number of nodes in the set is shown in parenthesis.

Important: Notes about working with the **XWatch** view:

- Expressions that reference variable names are not evaluated.
- The expression list is not deleted at the end of the transformation (it is preserved between debugging sessions).
- To insert a new expression, click the first empty line of the **Expression** column and start typing. As an alternative, right-click and select the **Add** action. Press **(Enter)** on the cell to add and evaluate.
- To delete an expression, click its **Expression** column and delete its content. As an alternative, right-click and select the **Remove** action. Press **(Enter)** on the cell to commit changes.
- If the expression result type is a *Node Set*, click it (**Value** column) and its value is displayed in the ***Nodes/Values Set** view*.
- The **Copy**, **Add**, **Remove** and **Remove All** actions are available in every row's contextual menu.

Messages View

Using **xsl:message** instructions is one way to signal special situations encountered during transformation as well as a raw way of doing the debugging. The **Messages** view is available only for XSLT debugging sessions and shows all `xsl:message` calls executed by the XSLT processor during transformation. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

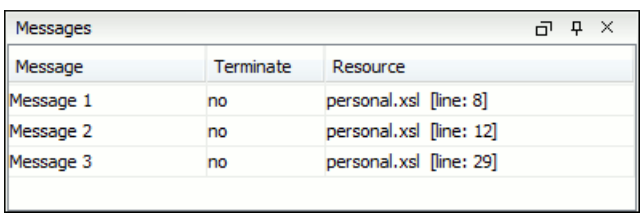

Figure 686: Messages View

Table 72: Messages columns

Column	Description
Message	Message content.
Terminate	Signals if processor terminates the transformation or not once it encounters the message (yes/no respectively).
Resource	Resource file where *xsl:message* instruction is defined and the message line number. The complete path of the resource is available as tooltip.

The following actions are available in the contextual menu:

Go to

Highlight the XSL fragment that generated the message.

Copy

Copies to clipboard message details (system ID, severity info, description, start location, terminate state).

Clear all

Removes all messages from the view.

Important:

- Clicking a record from the table highlights the `xsl:message` declaration line.
- Message table values can be sorted by clicking the corresponding column header. Clicking the column header switches the sorting order between: ascending, descending, no sort.

Stack View

The **Stack** view shows the current execution stack of both source and XSLT/XQuery nodes. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

During the transformation, two stacks are managed. One for source nodes being processed and the other for XSLT/XQuery nodes being processed. Oxygen XML Editor shows both node types in one common stack. The source (XML) nodes are preceded by a red color icon while XSLT/XQuery nodes are preceded by a green color icon. The advantage of this approach is that you can always see the source scope on which an XSLT/XQuery instruction is executed (the last red color node on the stack). The stack is oriented upside down.

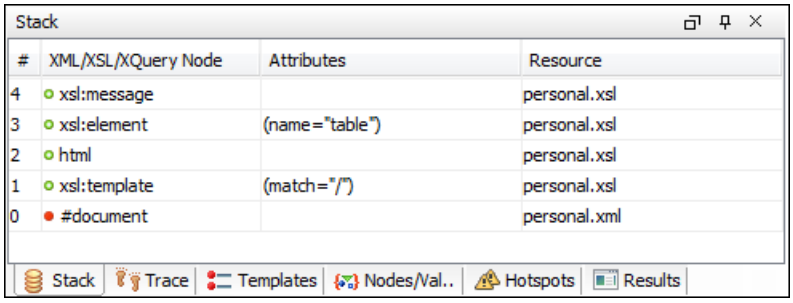

Figure 687: Stack View

The contextual menu contains one action: **Go to**, which moves the selection in the editor panel to the line containing the XSLT element that is displayed on the selected line from the view.

Table 73: Stack columns

Column	Description
#	Order number, represents the depth of the node (0 is the stack base).

Column	Description
XML/XSLT/XQuery Node	Node from source or stylesheet document currently being processed. One particular stack node is the document root, noted as **#document**.
Attributes	Attributes of the node (a list of *id="value"* pairs).
Resource	Resource file where the node is located. The entire path is available as tooltip.

Important: Remarks:

- Clicking a record from the stack highlights that node's location inside resource.
- Using Saxon, the stylesheet elements are qualified with XSL proxy, while using Xalan you only see their names. (example: `xsl:template` using Saxon and `template` using Xalan).
- Only the Saxon processor shows element attributes.
- The Xalan processor shows also the built-in rules.

Output Mapping Stack View

The **Output Mapping Stack** view displays *context data* and presents the XSLT templates/XQuery elements that generated specific areas of the output. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

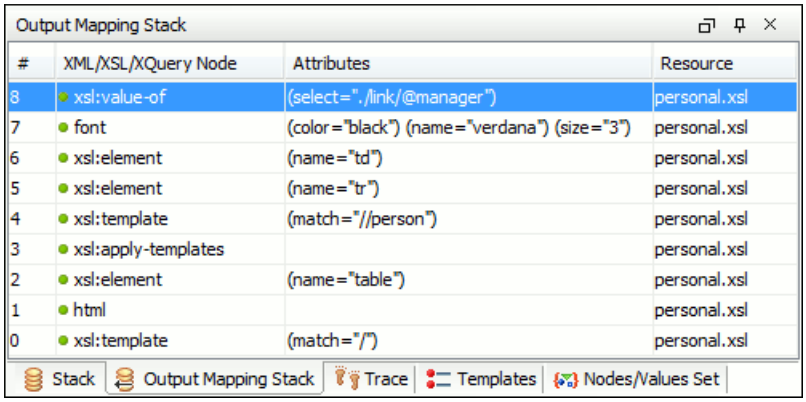

Figure 688: Output Mapping Stack view

The **Go to** action of the contextual menu takes you to the line that contains the XSLT element displayed in the **Output Mapping Stack** view.

Table 74: Output Mapping Stack columns

Column	Description
#	The order number in the stack of XSLT templates/ XQuery elements. Number 0 corresponds to the bottom of the stack in the status of the XSLT/ XQuery processor. The highest number corresponds to the top of the stack.
XSL/XQuery Node	The name of an XSLT template/XQuery element that participated in the generation of the selected output area.
Attributes	The attributes of the XSLT template/XQuery node.
Resource	The name of the file containing the XSLT template/ XQuery element.

Important: Remarks:

- Clicking a record highlights that XSLT template definition/XQuery element inside the resource (XSLT stylesheet file/XQuery file).
- Saxon only shows the applied XSLT templates having at least one hit from the processor. Xalan shows all defined XSLT templates, with or without hits.
- The table can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in XSLT rules.

Related Information:

Identify the XSLT / XQuery Expression that Generated Particular Output on page 1372
Stack View on page 1365
Trace View on page 1367
Templates View on page 1368

Trace View

Usually, the XSLT/XQuery processors signal the following events during transformation:

- - Entering a source (XML) node.
- - Leaving a source (XML) node.
- - Entering an XSLT/XQuery node.
- - Leaving an XSLT/XQuery node.

The **Trace** view catches all of these events, so you can see how the process evolved. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

The red icon lines denote source nodes while the green icon lines denote XSLT/XQuery nodes. It is possible to save the element trace in a structured XML document (using the **Export to XML** action in the contextual menu). Thus, you have the possibility of comparing the trace results from multiple debug sessions.

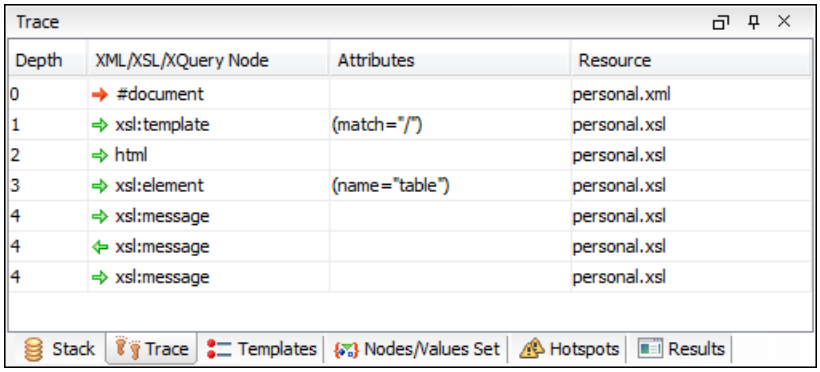

Figure 689: Trace History View

The contextual menu contains the following actions:

Go to

Moves the selection in the editor panel to the line containing the XSLT element or XML element that is displayed on the selected line from the view;

Export to XML

Saves the entire trace list in XML format.

Table 75: Trace History columns

Column	Description
Depth	Shows you how deep the node is nested in the XML or stylesheet structure. The bigger the number, the more nested the node is. A depth 0 node is the document root.
XML/XSLT/XQuery Node	Represents the node from the processed source or stylesheet document. One particular node is the document root, noted as *#document*. Every node is preceded by an arrow that represents what action was performed on it (entering or leaving the node).
Attributes	Attributes of the node (a list of *id="value"* pairs).
Resource	Resource file where the node is located. The complete path of the resource file is provided as tooltip.

Important: Remarks:

- Clicking a record highlights that node's location inside the resource.
- Only the Saxon processor shows the element attributes.
- The Xalan processor shows also the built-in rules.

Templates View

The **xsl:template** is the basic element for stylesheets transformation. The **Templates** view is only available during XSLT debugging sessions and shows all *xsl:template* instructions used by the transformation. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Being able to see the number of *hits* for each of the templates allows you to get an idea of the stylesheet coverage by template rules with respect to the input source.

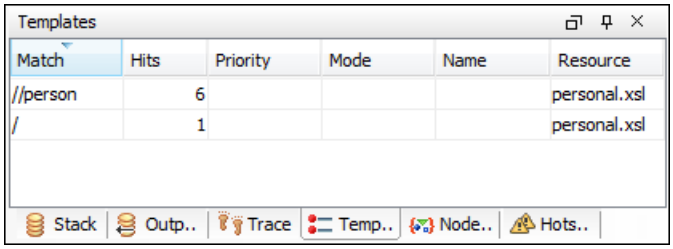

Figure 690: Templates view

The contextual menu contains one action: **Go to**, which moves the selection in the editor panel to the line that contains the XSLT template displayed on the selected line from the view.

Table 76: Templates columns

Column	Description
Match	The *match* attribute of the *xsl:template*.
Hits	The number of hits for the *xsl:template*. Shows how many times the XSLT processor used this particular template.
Priority	The template priority as established by XSLT processor.
Mode	The *mode* attribute of the *xsl:template*.
Name	The *name* attribute of the *xsl:template*.

Column	Description
Resource	The resource file where the template is located. The complete path of the resource file is available as tooltip.

Important: Remarks:

- Clicking a record highlights that template definition inside the resource.
- Saxon only shows the applied templates having at least one hit from the processor. Xalan shows all defined templates, with or without hits.
- Template table values can be sorted by clicking the corresponding column header. When clicking a column header the sorting order switches between: ascending, descending, no sort.
- Xalan shows also the built-in rules.

Nodes/Values Set View

The **Nodes/Values Set** view is always used in relation with the ***Variables*** *view* and ***XWatch*** *view*. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu. It shows an XSLT node set value in a tree form. This view is updated as a response to the following events:

- You click a variable that has a node set value in the ***Variables*** or ***XWatch*** *view*.
- You click a tree fragment in the ***Variables*** or ***XWatch*** *view*.
- You click an XPath expression evaluated to a node set in the ***Variables*** or ***XWatch*** *view*.

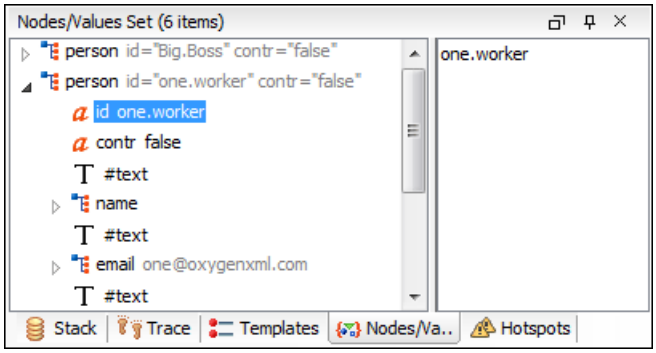

Figure 691: Node Set view

The nodes / values set is presented in a tree-like fashion. The total number of items is presented in the title bar. Nodes from a defined namespace bound to a prefix are displayed using the qualified name. If the namespace is not bound to a prefix, the namespace URI is presented before the node name. The value of the selected attribute or node is displayed in the right side panel.

Important: Remarks:

- For longer values in the right side panel, the interface displays it with an ellipsis (...) at the end. A more detailed value is available as a tooltip when hovering over it.
- Clicking a record highlights the location of that node in the source or stylesheet view.

Variables View

The **Variables** view displays variables and parameters (local and global), along with their values. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

Variables and parameters play an important role during an XSLT/XQuery transformation. Oxygen XML Editor uses the following icons to differentiate variables and parameters:

- V - Global variable.
- {V} - Local variable.
- P - Global parameter.
- {P} - Local parameter.

The following value types are available:

- **Boolean**
- **String**
- **Date** - XSLT 2.0 / 3.0 only.
- **Number**
- **Set**
- **Object**
- **Fragment** - Tree fragment.
- **Any**
- **Undefined** - The value was not yet set, or it is not accessible.

  Note:

  When Saxon 6.5 is used, if the value is unavailable, then the following message is displayed in the **Value** field: "The variable value is unavailable".

  When Saxon 9 is used:

  - If the variable is not used, the **Value** field displays "The variable is declared but never used".
  - If the variable value cannot be evaluated, the **Value** field displays "The variable value is unavailable".
- **Document**
- **Element**
- **Attribute**
- **ProcessingInstruction**
- **Comment**
- **Text**
- **Namespace**
- **Evaluating** - Value under evaluation.
- **Not Known** - Unknown types.

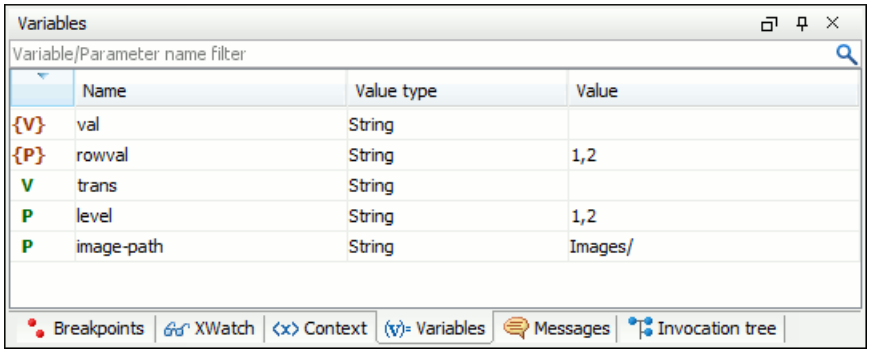

Figure 692: Variables View

Table 77: Variables Columns

Column	Description
Name	Name of variable / parameter.
Value Type	Type of variable/parameter.
Value	Current value of variable / parameter.

The value of a variable (the **Value** column) can be copied to the clipboard for pasting it to other editor areas with the **Copy value** action from the contextual menu. This is useful if you have long and complex values that cannot be easily remembered just by looking at them once.

Important: Remarks:

- Local variables and parameters are the first entries presented in the table.

- Clicking a record highlights the variable definition line.
- Variable values could differ depending on the transformation engine used or stylesheet version set.
- If the value of the variable is a node set or a tree fragment, clicking it causes the ***Node Set*** *view* to be shown with the corresponding set of values.
- Variable table values can be sorted by clicking the corresponding column header. Clicking the column header switches between the orders: ascending, descending, no sort.

Multiple Output Documents in XSLT 2.0 and XSLT 3.0

For XSLT 2.0 and XSLT 3.0 stylesheets that store the output in multiple files by using the `xsl:result-document` instruction, the content of the file created in this way is displayed dynamically while the transformation is running in an output view. There is one view for each `xsl:result-document` instruction so that the output is not mixed while still being presented in multiple views.

Steps in a Typical Debugging Process

Depending on your situation and needs, the debugging process might be more complex, but the following procedure is an example of a typical debugging process:

1. *Open the source XML document* and *the XSLT/XQuery document.*
2. If you are in the **Editor** *perspective*, switch to the **XSLT Debugger** or **XQuery Debugger** *perspective* with one of the following actions:
   - Select **Window** > **Open perspective** > **XSLT Debugger/XQuery Debugger** or the **XSLT Debugger**/**XQuery Debugger** button in the top-right corner of the interface.
   - Select **Document** > **XML Document** > **Debug scenario** or use the **Debug scenario** action on the toolbar.. This action initializes the Debugger *perspective* with the parameters of the transformation scenario. Any modification applied to the scenario parameters (the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the scenario when exiting from the Debugger *perspective*.
3. Select the source XML document in the *XML source selector of the Control toolbar*. In the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector value to **NONE**.
4. Select the XSLT/XQuery document in the *XSL/XQuery selector of the Control toolbar*.
5. Set XSLT/XQuery parameters using the ***Configure parameters*** *button on the Control toolbar*.
6. *Set one or more breakpoints*.
7. Step through the stylesheet using the *following buttons available on the Control toolbar*:
   - **Step into**
   - **Step over**
   - **Step out**
   - **Run**
   - **Run to cursor**
   - **Run to end**
   - **Pause**
   - **Stop**
8. Examine the data in the information views to find the bug in the transformation process.

   For more information about fixing bugs in the transformation, see: *Identify the XSLT / XQuery Expression that Generated Particular Output* on page 1372.

Related Information:

Identify the XSLT / XQuery Expression that Generated Particular Output on page 1372

Identify the XSLT / XQuery Expression that Generated Particular Output

To quickly spot the XSLT templates or XQuery expressions with problems, it is important to know what XSLT template in the XSLT stylesheet (or XQuery expression in the XQuery document) and what element in the source XML document generated a specified area in the output.

Some of the debugging capabilities (for example, **Step in**) can be used for this purpose. Using **Step in**, you can see how output is generated and link it with the XSLT/XQuery element being executed in the current source context. However, this can become difficult on complex XSLT stylesheets or XQuery documents that generate a large output.

You can click particular text in the **Output** view or **XHTML** output view and the editor will select the XML source context and the XSLT template/XQuery element that generated that text. Also, inspecting the whole stack of XSLT templates/XQuery elements that determined the state of the XSLT/XQuery processor at the moment of generating the specified output area speeds up the debugging process.

This is an example of a typical procedure for identifying an expression that generated particular output:

1. Switch to the **XSLT Debugger** or **XQuery Debugger** *perspective* with one of the following actions:
   - Select **Window** > **Open perspective** > **XSLT Debugger/XQuery Debugger** or the **XSLT Debugger**/**XQuery Debugger** button in the top-right corner of the interface.
   - Select **Document** > **XML Document** > **Debug scenario** or use the **Debug scenario** action on the toolbar.. This action initializes the Debugger *perspective* with the parameters of the transformation scenario. Any modification applied to the scenario parameters (the transformer engine, XSLT parameters, transformer extensions, etc.) will be saved back in the scenario when exiting from the Debugger *perspective*.
2. Select the source XML document in the *XML source selector of the Control toolbar*. In the case of XQuery debugging, if your XQuery document has no implicit source, set the source selector value to **NONE**.
3. Select the XSLT/XQuery document in the *XSL/XQuery selector of the Control toolbar*.
4. Select the appropriate engine in the *XSLT/XQuery engine selector of the Control toolbar*.
5. Set XSLT/XQuery parameters using the ***Configure parameters*** *button on the Control toolbar*.
6. Apply the XSLT stylesheet or XQuery transformation using the ***Run to end*** *button that is available on the Control toolbar*.
7. Inspect the mapping by clicking a section of the output in either the **Text** tab or **XHTML** tab of the *Output view*.

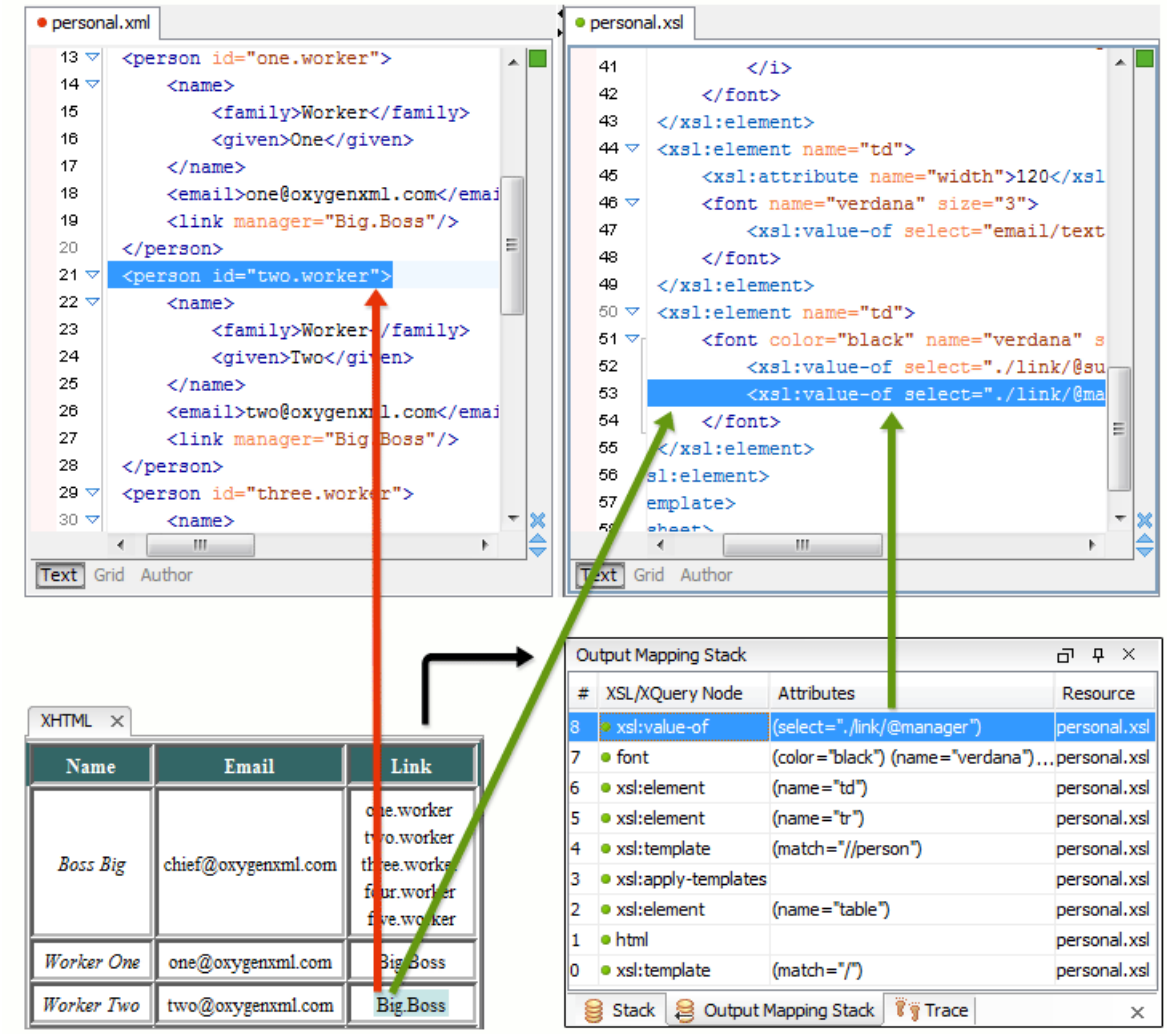

Figure 693: XHTML Output to Source Mapping

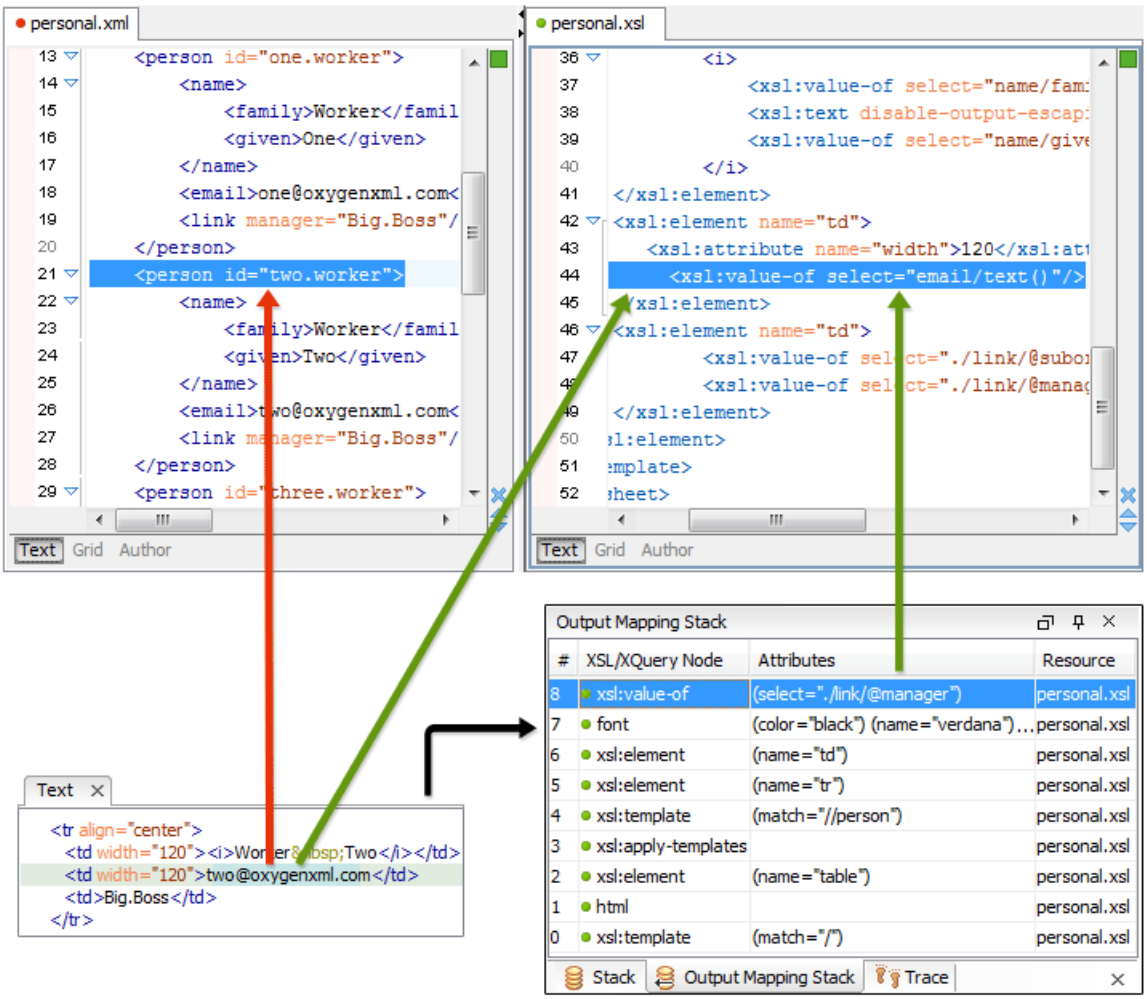

Figure 694: Text Output to Source Mapping

This action will highlight the XSLT / XQuery element and the XML source context. This XSLT template/XQuery element that is highlighted in the XSLT/XQuery editor represents only the top of the stack of XSLT templates/ XQuery elements that determined the state of the XSLT/XQuery processor at the moment of generating the clicked output section. In the case of complex transformations, inspecting the whole stack of XSLT templates/ XQuery elements speeds up the debugging process. This stack is available in the ***Output Mapping Stack*** *view*.

Related Information:

Output Mapping Stack View on page 1366

Templates View on page 1368

Using Breakpoints

The Oxygen XML Editor XSLT/XQuery Debugger allows you to interrupt XSLT/XQuery processing to gather information about variables and processor execution at particular points. To ensure *breakpoints* are persistent between work sessions, they are saved at project level. You can set a maximum of 100 *breakpoints* per project.

Inserting Breakpoints

To insert a *breakpoint*, follow these steps:

1. Click the line where you want to insert the *breakpoint* in the XML source document or the XSLT/XQuery document. *Breakpoints* are automatically created on the ending line of a start tag, even if you click a different line.
2. Click the vertical stripe on the left side of the editor panel or use **Shift+F7**.

Result:

Once you insert a *breakpoint*, it is automatically added to the list in the **Breakpoints** view and you can edit its associated *condition*. A *breakpoint* can have an associated break condition that represents an XPath expression evaluated in the current debugger context. In order to be processed, their evaluation result should be a boolean value. A *breakpoint* with an associated condition only stops the execution of the Debugger if the *breakpoint condition* is evaluated as **true**.

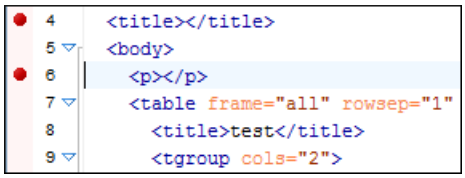

Figure 695: Example: Breakpoints

Removing Breakpoints

To remove a *breakpoint*, click its icon (●) in the vertical stripe on the left side of the editor panel or right-click the *breakpoint* and select **Renove** or **Remove all**.

Related Information:

Breakpoints View on page 1362

Performance Profiling of XSLT Stylesheets and XQuery Documents

Whether you are trying to identify a performance issue that is causing your production XSLT/XQuery transformation to not meet customer expectations or you are trying to proactively identify issues prior to deploying your XSLT/XQuery transformation, using the XSLT/XQuery profiler feature is essential to helping you save time and ultimately ensure a better performing, more scalable XSLT/XQuery transformation.

The XSLT/XQuery profiling feature can use any available XSLT/XQuery processor that can be used for debugging and it is available from the debugging *perspective*.

Enabling the Profiler

Enabling and disabling the profiler is controlled by the ***Profiler*** *button from the debugger Control toolbar*. The XSLT/XQuery profiler is off by default. This option is not available during a debugger session so you need to set it before starting the transformation. For information about a common debugging procedure, see *Steps in a Typical Debugging Process* on page 1371.

Profiling Information Views

Immediately after enabling the profiler, two new information views are added to the current debugger *information views*:

- ***Invocation tree*** *view* on left side
- ***Hotspots*** *view* on right side

Profiling data is available only after the transformation ends successfully.

On the left side (***Invocation tree*** *view*), you can examine how style instructions are processed. This result view is also named call-tree, as it represents the order of style processing. The profiling result shows the duration time for each of the style-instruction including the time needed for its called children.

On the right side (***Hotspots** view*), you can immediately spot the time the processor spent in each instruction. As an instruction usually calls other instructions, the used time of the called instruction is extracted from the duration time of the caller (the hotspot only presents the inherent time of the instruction).

Source Backmapping

In either the ***Invocation tree*** or ***Hotspots** view*, you can use the backmapping feature to find the XSLT stylesheet or XQuery expression definition. Clicking the selected item causes Oxygen XML Editor to highlight the XSLT stylesheet or XQuery expression source line where the instruction is defined.

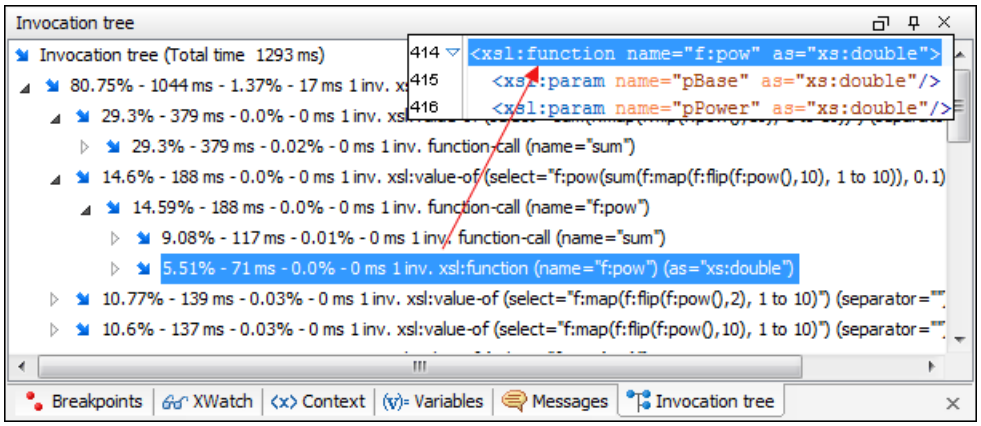

Figure 696: Source Backmapping

Saving and Customizing Profiling Data

The profiling data can be saved (exported) into XML and HTML format. In either the ***Invocation tree*** or ***Hotspots** view*, right-click anywhere in the view and select **Export to XML** or **Export to HTML**. The HTML report can be customized based upon the profiling raw data. When you select **Export to HTML**, Oxygen XML Editor will save it as XML and apply an XSLT stylesheet to render the report as XML. You can customize these stylesheets to suit your needs. They are located in: *[OXYGEN_INSTALL_DIR]*`/frameworks/profiler/`.

Other Profiling Notes

- If you want to change the *XSLT/XQuery profiler settings*, use the contextual menu and choose the corresponding **View settings** entry.
- Profiling exhaustive transformations may run into an **OutOfMemory** error due to the large amount of information being collected. If this is the case, you can close unused projects when running the profiling or use high values for Java VM options `-Xms` and `-Xmx`. If this does not help you can shorten your source XML file and try again.
- For more information about the XSLT/XQuery Profiler, watch our video demonstration:

Invocation Tree View

The **Invocation Tree** view shows a top-down call tree that represents how XSLT instructions or XQuery expressions are processed. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

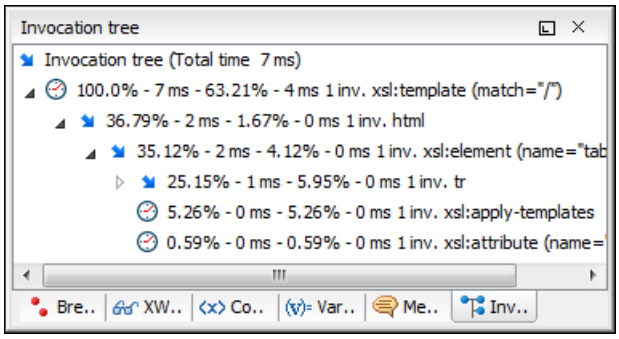

Figure 697: Invocation Tree View

The entries in the invocation tree include a few possible icons that indicate the following:

- - Points to a call whose inherent time is insignificant compared to its total time.
- - Points to a call whose inherent time is significant compared to its total time (greater than 1/3rd of its total time).

Every entry in the invocation tree includes textual information that depends on the ***XSLT/XQuery profiler settings***:

- A percentage number of the total time that is calculated with respect to either the root of the tree or the calling instruction.
- A total time measurement in milliseconds or microseconds. This is the total execution time that includes calls into other instructions.
- A percentage number of the inherent time that is calculated with respect to either the root of the tree or the calling instruction.
- An inherent time measurement in milliseconds or microseconds. This is the inherent execution time of the instruction.
- An invocation count that shows how often the instruction has been invoked on this call-path.
- An instruction name that contains also the attributes description.

The **Invocation Tree** view also includes the following contextual menu actions:

Export to HTML

Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the subfolder: *[OXYGEN_INSTALL_DIR]*`/frameworks/profiler/`. You can use them to customize your own report based on the profiling raw data.

Export to XML

Use this option to save the profiling data as an XML file in a specified location.

View settings

Opens the *XSLT/XQuery Profiler preferences page* that allows you to configure various profiling settings.

Hotspots View

The **Hotspots** view displays a list of all instruction calls that lie above the threshold defined in the ***XSLT/XQuery profiler settings***. If the view is not displayed, it can be opened by selecting it from the **Window** > **Show View** menu.

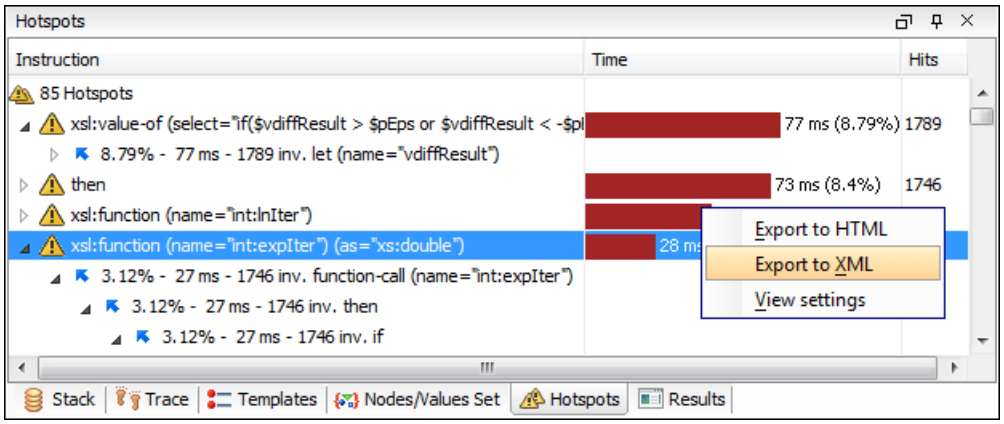

Figure 698: Hotspots View

By opening a hotspot instruction entry, the tree of back-traces leading to that instruction call are calculated and shown.

Every hotspot is described by the values from the following columns:

- **Instruction** - The name of the instruction.
- **Time** - The inherent time in milliseconds or microseconds of how much time has been spent in the hotspot, along with a bar whose length is proportional to this value. All calls into this instruction are summed up regardless of the particular call sequence.
- **Hits** - The invocation count of the hotspot entry.

If you click the ⚠ handle on the left side of a hotspot, a tree of back-traces will be shown.

Every entry in the backtrace tree has textual information attached to it that depends on the ***XSLT/XQuery profiler settings***:

- A percentage number that is calculated with respect to either the total time or the called instruction.
- A time measured in milliseconds or microseconds of how much time has been contributed to the parent hotspot on this call-path.
- An invocation count that shows how often the hotspot has been invoked on this call-path.

  Note: This is not the number of invocations of this instruction.
- An instruction name that also contains its attributes.

The **Hotspots** view also includes the following contextual menu actions:

Export to HTML

Selecting this option will save the profiling data as XML and then apply an XSLT stylesheet to render the report as HTML. These stylesheets are included in the subfolder: *[OXYGEN_INSTALL_DIR]*`/frameworks/profiler/`. You can use them to customize your own report based on the profiling raw data.

Export to XML

Use this option to save the profiling data as an XML file in a specified location.

View settings

Opens the *XSLT/XQuery Profiler preferences page* that allows you to configure various profiling settings.

Debugging XSLT that Call Java Extensions

It is possible to debug XSLT that call Java extensions. This is achieved through a transformation scenario in which the Java extensions are specified, and the debugging can be done based upon the same scenario.

To debug XSLT with Java extensions, follow this procedure:

1. Create an *XSLT transformation scenario* for your XSLT document (select **Configure Transformation Scenario(s)** action from the toolbar, then click **New**, and select **XSLT transformation**).

2. In the **New scenario** dialog box, click the **Extensions** button (in the **XSLT** tab), specify the Java extensions (JAR libraries) that are needed, and click **OK**.
3. Once you are finished configuring the transformation scenario, click **OK**, then select **Save and close**.
4. Use the **Debug scenario** action on the toolbar and the debugging will be based upon the same transformation scenario you just configured and saved.

Tip: You could achieve this during a *typical debugging process* by specifying the Java extensions using the ***Edit extensions*** *button on the debugger control toolbar*.

Related Information:

Validating XSLT Stylesheets that Call Java Extensions on page 725

Debugging Java Extensions

The XSLT/XQuery debugger does not step into Java classes that are configured as XSLT/XQuery extensions of the transformation. To step into Java classes, inspect variable values, and set *breakpoints* in Java methods, you can set up a Java debug configuration in an IDE (such as the Eclipse SDK) as described in the following steps:

1. Create a debug configuration.
   a) Set at least 256 MB as heap memory for the Java virtual machine (recommended 512 MB) by setting the `-Xmx` parameter in the debug configuration (for example, "-Xmx512m").
   b) Make sure the *[OXYGEN_INSTALL_DIR]*`/lib/oxygen.jar` file and your Java extension classes are on the Java classpath.

      The Java extension classes should be the same classes that were *set as an extension* of the XSLT/XQuery transformation in the debugging *perspective*.
   c) Set the class *ro.sync.exml.Oxygen* as the main Java class of the configuration.

      The main Java class *ro.sync.exml.Oxygen* is located in the `oxygen.jar` file.
2. Start the debug configuration.

   Now you can set *breakpoints* and inspect Java variables as in any Java debugging process executed in the selected IDE (Eclipse SDK, and so on.).

Supported Processors for XSLT / XQuery Debugging

The following built-in XSLT processors are integrated in the debugger and can be selected in the *Control Toolbar*:

- Saxon 9.7.0.19 HE (Home Edition) - a limited version of the Saxon 9 processor, capable of running XSLT 1.0, XSLT 2.0 / 3.0 basic and XQuery 1.0 transformations, available in both the XSLT debugger and the XQuery one,
- Saxon 9.7.0.19 PE (Professional Edition) - capable of running XSLT 1.0 transformations, XSLT 2.0 basic ones and XQuery 1.0 ones, available in both the XSLT debugger and the XQuery one,
- Saxon 9.7.0.19 EE (Enterprise Edition) - a schema aware processor, capable of running XSLT 1.0 transformations, XSLT 2.0 /3.0 basic ones, XSLT 2.0 / 3.0 schema aware ones and XQuery 1.0 / 3.0 ones, available in both the XSLT debugger and the XQuery debugger,
- Saxon 6.5.5 - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger,
- Xalan 2.7.1 - capable of running only XSLT 1.0 transformations, available only in the XSLT debugger.

Author Mode Customization

- *Creating and Running Automated Tests*
- *API Frequently Asked Questions (API FAQ)*

This section contains an *Author Mode Customization Guide* on page 1380, *CSS Support in Author Mode* on page 1473, a collection of *Frequently Asked Questions regarding the Oxygen XML Editor API*, and other topics in regards to customizing the **Author** mode.

Author Mode Customization Guide

The **Author** mode editor of Oxygen XML Editor was designed to provide a user-friendly interface for editing XML documents. **Author** combines the power of source editing with the intuitive interface of a word processor. You can customize the **Author** mode editor to support new custom XML formats or to change how standard XML formats are edited.

Although Oxygen XML Editor includes built-in, configured *frameworks* for DocBook, DITA, TEI, and XHTML you might need to create a customization of the editor to handle other types of documents. A common use case is when your organization holds a collection of XML document types used to define the structure of internal documents and they need to be visually edited by people with no experience working with XML files.

There are several ways to customize the editor:

1. Create a CSS file defining styles for the XML elements you will work with, and create XML files that reference the CSS through an `xml-stylesheet` processing instruction.
2. Fully configure a *framework*. This involves putting together the CSS stylesheets, XML schemas, actions, menus, bundling them, and distributing an archive. The CSS and GUI elements are settings for the Oxygen XML Editor **Author** mode. The other settings such as the templates, catalogs, and transformation scenarios are general settings and are enabled whenever the association is active, regardless of the editing mode (**Text**, **Grid**, or **Author**).

Simple Customization Tutorial

The most important elements of a document type customization are represented by an XML Schema to define the XML structure, the CSS to render the information and the XML instance template that links the first two together.

XML Schema

To provide as-you-type validation and to compute valid insertion proposals, Oxygen XML Editor needs an XML grammar (XML Schema, DTD, or RelaxNG) associated to the XML. The grammar specifies how the internal structure of the XML is defined. For information about associating a schema and how Oxygen XML Editor detects the schema, see *Associating a Schema to XML Documents* on page 674.

Consider a use-case in which several users are testing a system and must send report results to a content management system. The customization should provide a visual editor for these kind of documents. The following XML Schema, `test_report.xsd` defines a report with results of a testing session. The report

consists of a title, few lines describing the test suite that was run, and a list of test results (each with a name and a boolean value indicating if the test passed or failed).

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">
    <xs:element name="report">
        <xs:complexType>
            <xs:sequence>
                <xs:element ref="title"/>
                <xs:element ref="description"/>
                <xs:element ref="results"/>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
    <xs:element name="title" type="xs:string"/>
    <xs:element name="description">
        <xs:complexType>
            <xs:sequence maxOccurs="unbounded">
                <xs:element name="line">
                    <xs:complexType mixed="true">
                        <xs:sequence minOccurs="0"
                            maxOccurs="unbounded">
                            <xs:element name="important"
                              type="xs:string"/>
                        </xs:sequence>
                    </xs:complexType>
                </xs:element>
            </xs:sequence>
        </xs:complexType>
    </xs:element>

    <xs:element name="results">
        <xs:complexType>
            <xs:sequence maxOccurs="unbounded">
                <xs:element name="entry">
                    <xs:complexType>
                        <xs:sequence>
                            <xs:element name="test_name"
                              type="xs:string"/>
                            <xs:element name="passed"
                               type="xs:boolean"/>
                        </xs:sequence>
                    </xs:complexType>
                </xs:element>
            </xs:sequence>
        </xs:complexType>
    </xs:element>
</xs:schema>
```

CSS Stylesheet

A set of rules must be defined for describing how the XML document is to be rendered in **Author** mode. This is done using Cascading Style Sheets (CSS). CSS is a language used to describe how an HTML or XML document should be formatted by a browser. CSS is widely used in the majority of websites.

The elements from an XML document are displayed in the layout as a series of boxes. Some of the boxes contain text and may flow one after the other, from left to right. These are called inline boxes. There are also other type of boxes that flow one below the other (such as paragraphs). These are called block boxes.

For example, consider the way a traditional text editor arranges the text. A paragraph is a block, because it contains a vertical list of lines. The lines are also blocks. However, blocks that contains inline boxes arrange its children in a horizontal flow. That is why the paragraph lines are also blocks, while the traditional "bold" and "italic" sections are represented as inline boxes.

The CSS allows us to specify that some elements are displayed as tables. In CSS, a table is a complex structure and consists of rows and cells. The `table` element must have children that have a *table-row* style. Similarly, the `row` elements must contain elements with a *table-cell* style.

To make it easy to understand, the following section describes how each element from a schema is formatted using a CSS file. Note that this is just one of infinite possibilities for formatting the content.

`report`

This element is the root element of a report document. It should be rendered as a box that contains all other elements. To achieve this the display type is set to **block**. Additionally, some margins are set for it. The CSS rule that matches this element is:

```
report{
    display:block;
    margin:1em;
```

```
}
```

`title`

The title of the report. Usually titles have a large font. The **block** display is used so that the subsequent elements will be placed below it, and its font is changed to double the size of the normal text.

```
title {
    display:block;
    font-size:2em;
}
```

`description`

This element contains several lines of text describing the report. The lines of text are displayed one below the other, so the description has the **block** display. Also, the background color is changed to make it standout.

```
description {
    display:block;
    background-color:#EEEEFF;
    color:black;
}
```

`line`

A line of text in the description. A specific aspect is not defined and it just indicates that the display should be **block** style.

```
line {
    display:block;
}
```

`important`

The `important` element defines important text from the description. Since it can be mixed with text, its display property must be set to **inline**. Also, the text is emphasized with **bold**to make it easier to spot.

```
important {
    display:inline;
    font-weight:bold;
}
```

`results`

The `results` element displays the list of *test_names* and the results for each one. To make it easier to read, it is displayed as a **table**, with a green border and margins.

```
results{
    display:table;
    margin:2em;
    border:1px solid green;
}
```

`entry`

An item in the results element. The results are displayed as a table so the entry is a row in the table. Thus, the display is **table-row**.

```
entry {
    display:table-row;
}
```

`test_name`, `passed`

The name of the individual test, and its result. They are cells in the results table with the display set to **table-cell**. Padding and a border are added to emphasize the table grid.

```
test_name, passed{
    display:table-cell;
    border:1px solid green;
    padding:20px;
}

passed{
    font-weight:bold;
```

```
}
```

The full content of the CSS file `test_report.css` is:

```
report {
    display:block;
    margin:1em;
}

description {
    display:block;
    background-color:#EEEEFF;
    color:black;
}

line {
    display:block;
}

important {
    display:inline;
    font-weight:bold;
}

title {
    display:block;
    font-size:2em;
}

results{
    display:table;
    margin:2em;
    border:1px solid green;
}

entry {
    display:table-row;
}

test_name, passed{
    display:table-cell;
    border:1px solid green;
    padding:20px;
}

passed{
    font-weight:bold;
}
```

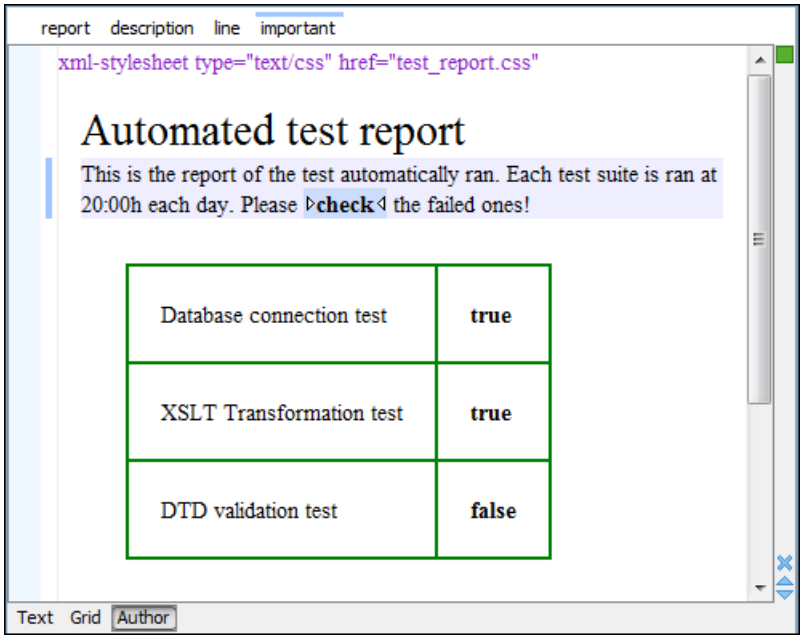

Figure 699: Report Rendered in Author Mode

Note: You can edit attributes in-place in the **Author** mode using *form-based controls*.

Associating a Stylesheet with an XML Document

The rendering of an XML document in the **Author** mode is driven by a CSS stylesheet that conforms to the *version 2.1 of the CSS specification* from the W3C consortium. Some CSS 3 features, such as namespaces and custom extensions, of the CSS specification are also supported. Oxygen XML Editor also supports stylesheets coded with the LESS dynamic stylesheet language.

There are several methods for associating a stylesheet (CSS or LESS) with an XML document:

1. Insert the `xml-stylesheet` processing instruction with the `type` attribute at the beginning of the XML document. If you do not want to alter your XML documents, *you should create a new document type (framework)*.

   CSS example:

   ```
   <?xml-stylesheet type="text/css" href="test.css"?>
   ```

   LESS example:

   ```
   <?xml-stylesheet type="text/css" href="test.less"?>
   ```

   Note: XHTML documents need a `link` element, with the `href` and `type` attributes in the `head` child element, as specified in the *W3C CSS specification*. XHTML example:

   ```
   <link href="/style/screen.css" rel="stylesheet" type="text/css"/>
   ```

   Tip: You can also insert the `xml-stylesheet` processing instruction by using the **Associate XSLT/CSS Stylesheet** action that is available on the toolbar or in the **Document** > **XML Document** menu.
2. Add a new CSS or LESS file to a *framework* (document type). To do so, *open the **Preferences** dialog box (**Options** > **Preferences**)* and go to **Document Type Association**. Edit the appropriate *framework*, open the **Author** tab, then the **CSS** subtab. Press the **New** button to add a new CSS or LESS file.

   Note: The predefined *frameworks* are read-only, so you need to ***Extend*** or ***Duplicate*** them to configure them as custom *frameworks*.

You can read more about associating a CSS to a document type in *Customizing the Main CSS of a Framework*.

If a document has no CSS association or the referenced stylesheet files cannot be loaded, a default one is used. A warning message is also displayed at the beginning of the document, presenting the reason why the CSS cannot be loaded.

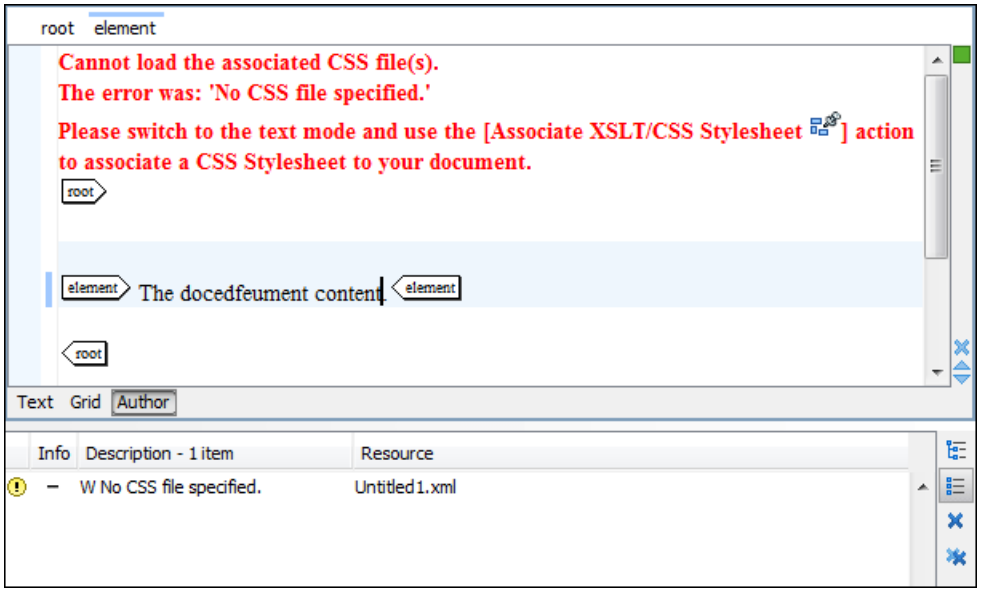

Figure 700: Document with no CSS association default rendering

XML Instance Template

Based on the XML Schema and CSS file Oxygen XML Editor can help the content author in loading, editing, and validating the test reports. An XML file template must be created as a kind of skeleton that the users can use as a starting point for creating new test reports. The template must be generic enough and reference the XML Schema file and the CSS stylesheet.

This is an example:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/css" href="test_report.css"?>
<report xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
  xsi:noNamespaceSchemaLocation="test_report.xsd">
  <title>Automated test report</title>
  <description>
    <line>This is the report of the test automatically ran.
      Each test suite is ran at 20:00h each day.
      Please <important>check</important> the failed ones!</line>
  </description>
  <results>
    <entry>
      <test_name>Database connection test</test_name>
      <passed>true</passed>
    </entry>
    <entry>
      <test_name>XSLT Transformation test</test_name>
      <passed>true</passed>
    </entry>
    <entry>
      <test_name>DTD validation test</test_name>
      <passed>false</passed>
    </entry>
  </results>
</report>
```

The processing instruction `xml-stylesheet` associates the CSS stylesheet to the XML file. The `href` pseudo attribute contains the URI reference to the stylesheet file. In our case the CSS is in the same directory as the XML file.

The next step is to place the XSD file and the CSS file on a web server and modify the template to use the HTTP URLs, like this:

```
<?xml version="1.0" encoding="UTF-8"?>
<?xml-stylesheet type="text/css"
        href="http://www.mysite.com/reports/test_report.css"?>
<report xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
        xsi:noNamespaceSchemaLocation=
        "http://www.mysite.com/reports/test_report.xsd">
    <title>Test report title</title>
    <description>
.......
```

If you want to share the files with other team members, you could create an archive containing the *`test_report.xml`*, *`test_report.css`*, and *`test_report.xsd`* and send it to the other users.

Advanced Framework Customization

Oxygen XML Editor supports individual document types and classes of document types through *frameworks*. A *framework* associates a document type or a class of documents with CSS stylesheets, validation schemas, catalog files, new files templates, transformation scenarios, and custom actions.

In this tutorial, we create a *framework* for a set of documents. As an example, we create a light documentation *framework* (similar to DocBook), then we set up a complete customization of the **Author** mode.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Related Information:

Document Types and Frameworks on page 972
Predefined Document Types (Frameworks) on page 972

Creating the Basic Association

Let us go through an example of creating a custom document type (*framework*) and editing an XML document of this type.

First Step - XML Schema

To illustrate an example of creating an XML Schema a custom DocBook *framework*, suppose the documents are either `articles` or books, both composed of `sections`. The `sections` may contain `titles`, `paragraphs`, `figures`, `tables`, and other `sections`. To complete the picture, each section includes a `def` element from another namespace.

The first schema file:

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
    targetNamespace="http://www.oxygenxml.com/sample/documentation"
    xmlns:doc="http://www.oxygenxml.com/sample/documentation"
    xmlns:abs="http://www.oxygenxml.com/sample/documentation/abstracts"
    elementFormDefault="qualified">

    <xs:import namespace=
    "http://www.oxygenxml.com/sample/documentation/abstracts"
     schemaLocation=
    "abs.xsd"/>
```

The namespace of the documents will be `http://www.oxygenxml.com/sample/documentation`. The namespace of the `def` element is `http://www.oxygenxml.com/sample/documentation/abstracts`.

Next, we define the structure of the sections. They all start with a title, then have the optional `def` element then either a sequence of other sections, or a mixture of paragraphs, images and tables.

```
<xs:element name="book" type="doc:sectionType"/>
<xs:element name="article" type="doc:sectionType"/>
<xs:element name="section" type="doc:sectionType"/>

<xs:complexType name="sectionType">
    <xs:sequence>
        <xs:element name="title" type="xs:string"/>
        <xs:element ref="abs:def" minOccurs="0"/>
        <xs:choice>
            <xs:sequence>
                <xs:element ref="doc:section" maxOccurs="unbounded"/>
            </xs:sequence>
            <xs:choice maxOccurs="unbounded">
                <xs:element ref="doc:para"/>
                <xs:element ref="doc:image"/>
                <xs:element ref="doc:table"/>
            </xs:choice>
        </xs:choice>
    </xs:sequence>
</xs:complexType>
```

The paragraph contains text and other styling markup, such as bold (b) and italic (`i`) elements.

```
<xs:element name="para" type="doc:paragraphType"/>

<xs:complexType name="paragraphType" mixed="true">
    <xs:choice minOccurs="0" maxOccurs="unbounded">
        <xs:element name="b"/>
        <xs:element name="i"/>
    </xs:choice>
</xs:complexType>
```

The `image` element has an attribute with a reference to the file containing image data.

```
<xs:element name="image">
    <xs:complexType>
        <xs:attribute name="href" type="xs:anyURI" use="required"/>
    </xs:complexType>
</xs:element>
```

The `table` contains a header row and then a sequence of rows (`tr` elements) each of them containing the cells. Each cell has the same content as the paragraphs.

```
 <xs:element name="table">
    <xs:complexType>
      <xs:sequence>
        <xs:element name="header">
            <xs:complexType>
               <xs:sequence>
                   <xs:element name="td" maxOccurs="unbounded"
                        type="doc:paragraphType"/>
               </xs:sequence>
            </xs:complexType>
```

```
        </xs:element>
        <xs:element name="tr" maxOccurs="unbounded">
            <xs:complexType>
               <xs:sequence>
                   <xs:element name="td" type="doc:tdType"
                               maxOccurs="unbounded"/>
                </xs:sequence>
            </xs:complexType>
        </xs:element>
      </xs:sequence>
    </xs:complexType>
</xs:element>

<xs:complexType name="tdType">
    <xs:complexContent>
        <xs:extension base="doc:paragraphType">
            <xs:attribute name="row_span" type="xs:integer"/>
            <xs:attribute name="column_span" type="xs:integer"/>
        </xs:extension>
    </xs:complexContent>
</xs:complexType>
```

The `def` element is defined as a text only element in the imported schema `abs.xsd`:

```
<?xml version="1.0" encoding="UTF-8"?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema"
    targetNamespace=
     "http://www.oxygenxml.com/sample/documentation/abstracts">
    <xs:element name="def" type="xs:string"/>
</xs:schema>
```

Now the XML data structure will be styled.

Schema Settings

In the bottom section of the ***Document Type*** *configuration dialog box*, there are a series of tabs. The first one refers to the schema that is used for validation of the documents that match the defined **Association Rules**.

Important: If the document references a schema using a DOCTYPE declaration or a `xsi:schemaLocation` attribute, the schema from the document type configuration will not be used when validating.

Schema Type

Select from the combo box the value **XML Schema**.

Schema URI

Enter the value of the schema location (for example, `${frameworks}/sdf/schema/sdf.xsd`). Use the ***${frameworks}*** *editor variable* in the schema URI path instead of a full path to be valid for multiple Oxygen XML Editor installations.

Important: The **${frameworks}** variable is expanded at the time of validation into the absolute location of the directory containing the *framework*.

Second Step - CSS

If you read the *Simple Customization Tutorial* then you already have some basic notions about creating simple styles. The example document contains elements from various namespaces, so you need to use CSS Level 3 extensions (supported by the **Author** mode layout engine) to associate specific properties with that element.

Defining the General Layout

Now the basic layout of the rendered documents is created.

Elements that are stacked one on top of the other are: book, `article`, `section`, `title`, `figure`, `table`, `image`. These elements are marked as having `block` style for display. Elements that are placed one after the other in a flowing sequence are: b, `i`. These will have `inline` display.

```
/* Vertical flow */
book,
section,
para,
title,
image,
ref {
    display:block;
}

/* Horizontal flow */
b,i {
```

```
    display:inline;
}
```

Important: Having `block` display children in an `inline` display parent results in Oxygen XML Editor changing the style of the parent to `block` display.

Styling the `section` Element

The title of any section must be bold and smaller than the title of the parent section. To create this effect, a sequence of CSS rules must be created. The `*` operator matches any element, it can be used to match titles having progressive depths in the document.

```
title{
    font-size: 2.4em;
    font-weight:bold;
}
* * title{
    font-size: 2.0em;
}
* * * title{
    font-size: 1.6em;
}
* * * * title{
    font-size: 1.2em;
}
```

It's useful to have before the title a constant text, indicating that it refers to a section. This text can include also the current section number. The `:before` and `:after` pseudo elements will be used, plus the CSS counters.

First declare a counter named `sect` for each `book` or `article`. The counter is set to zero at the beginning of each such element:

```
book,
article{
    counter-reset:sect;
}
```

The `sect` counter is incremented with each `section`, that is a direct child of a `book` or an `article` element.

```
book > section,
article > section{
    counter-increment:sect;
}
```

The "static" text that will prefix the section title is composed of the constant "Section ", followed by the decimal value of the `sect` counter and a dot.

```
book > section > title:before,
article > section > title:before{
    content: "Section " counter(sect) ". ";
}
```

To make the documents easy to read, you add a margin to the sections. In this way the higher nesting level, the larger the left side indent. The margin is expressed relatively to the parent bounds:

```
section{
    margin-left:1em;
    margin-top:1em;
}
```

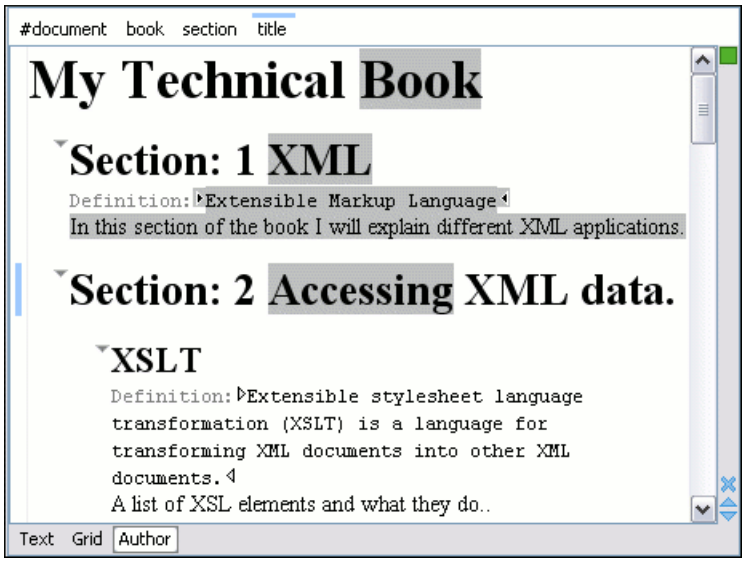

Figure 701: A sample of nested sections and their titles.

In the above screenshot you can see a sample XML document rendered by the CSS stylesheet. The selection "avoids" the text that is generated by the CSS "content" property. This happens because the CSS generated text is not present in the XML document and is just a visual aid.

Styling the Inline Elements

The "bold" style is obtained by using the `font-weight` CSS property with the value `bold`, while the "italic" style is specified by the `font-style` property:

```
b {
    font-weight:bold;
}

i {
    font-style:italic;
}
```

Styling Images

The CSS 2.1 does not specify how an element can be rendered as an image. To overpass this limitation, Oxygen XML Editor supports a CSS Level 3 extension allowing to load image data from a URL. The URL of the image must be specified by one of the element attributes and it is resolved through the catalogs specified in Oxygen XML Editor.

```
image{
    display:block;
    content: attr(href, url);
    margin-left:2em;
}
```

Our `image` element has the required attribute `href` of type `xs:anyURI`. The `href` attribute contains an image location so the rendered content is obtained by using the function:

```
attr(href, url)
```

The first argument is the name of the attribute pointing to the image file. The second argument of the `attr` function specifies the type of the content. If the type has the `url` value, then Oxygen XML Editor identifies the content as being an image. If the type is missing, then the content will be the text representing the attribute value.

Oxygen XML Editor handles both absolute and relative specified URLs. If the image has an *absolute* URL location (for example: "http://www.oasis-open.org/images/standards/oasis_standard.jpg") then it is loaded directly from this location. If the image URL is *relative* specified to the XML document (for example: "images/my_screenshot.jpg") then the location is obtained by adding this value to the location of the edited XML document.

An image can also be referenced by the name of a DTD entity that specifies the location of the image file. For example, if the document declares an entity **graphic** that points to a JPEG image file:

```
<!ENTITY graphic SYSTEM "depo/keyboard_shortcut.jpg" NDATA JPEG>
```

and the image is referenced in the XML document by specifying the name of the entity as the value of an attribute:

```
<mediaobject>
    <imageobject>
        <imagedata entityref="graphic" scale="50"/>
    </imageobject>
</mediaobject>
```

The CSS should use the functions `url`, `attr` and `unparsed-entity-uri` for displaying the image in the **Author** mode:

```
imagedata[entityref]{
    content: url(unparsed-entity-uri(attr(entityref)));
}
```

To take into account the value of the `width` attribute of the `imagedata` and use it for resizing the image, the CSS can define the following rule:

```
imagedata[width]{
  width:attr(width, length);
}
```

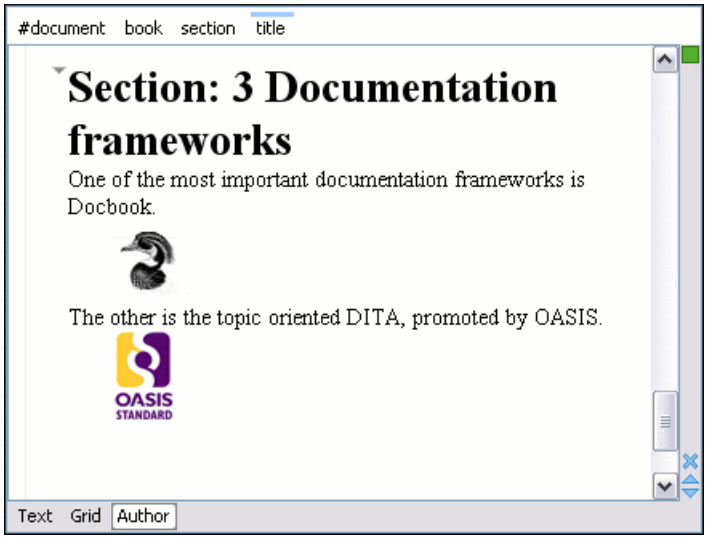

Figure 702: Samples of images in Author

Testing the Framework Customization

To test the new *framework* customization, create an XML instance that conforms with the association rules that you specified in your *framework* customization. You will not specify an XML Schema location directly in the document, using an `xsi:schemaLocation` attribute. Instead, Oxygen XML Editor will detect its associated document type and use the specified schema.

```
<book xmlns="http://www.oxygenxml.com/sample/documentation"
      xmlns:abs="http://www.oxygenxml.com/sample/documentation/abstracts">

    <title>My Technical Book</title>
    <section>
        <title>XML</title>
        <abs:def>Extensible Markup Language</abs:def>
        <para>In this section of the book I will
           explain different XML applications.</para>
    </section>
</book>
```

When trying to validate the document there should be no errors. Now modify the `title` to `title2`. Validate again. This time there should be as error.

```
cvc-complex-type.2.4.a: Invalid content was found starting with element
'title2'. One of '{"http://www.oxygenxml.com/sample/documentation":title}'
is expected.
```

Undo the tag name change, go to **Author** mode, and Oxygen XML Editor should load the CSS from the *document type association* and create a layout similar to this:

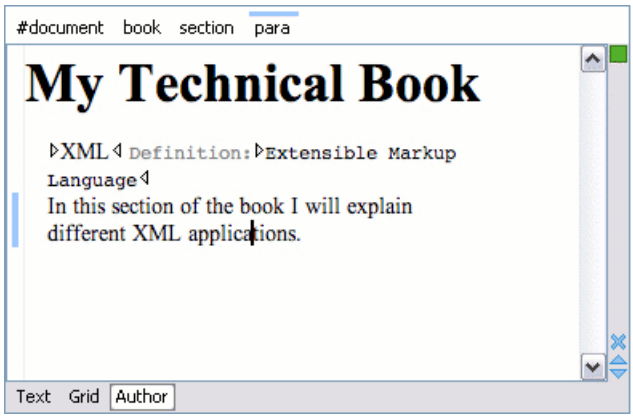

Figure 703: Example: Testing a Framework Customization

Organizing the Framework Files

First, create a new folder for your customized *framework* *[OXYGEN_INSTALL_DIR]*`/frameworks`. This folder will be used to store all files related to the documentation *framework*. The folder structure will look something like this:

```
oxygen
  frameworks
     sdf
       schema
       css
```

The `frameworks` directory is the container where all the Oxygen XML Editor *framework* customizations are located. Each subdirectory contains files related to a specific type of XML documents (schemas, catalogs, stylesheets, CSS stylesheets, etc.) Distributing a *framework* means delivering a *framework* directory.

It is assumed that you have the right to create files and folders inside the Oxygen XML Editor installation directory. If you do not have this right, you will have to install another copy of the program in a folder you have access to, the home directory for instance, or your desktop.

To test your *framework* distribution, copy it in the `frameworks` directory of the newly installed application and start Oxygen XML Editor by running the provided start-up script files.

You should copy the created schema files `abs.xsd` and `sdf.xsd`, `sdf.xsd` being the master schema, to the `schema` directory and the CSS file `sdf.css` to the `css` directory.

Packaging and Deploying

Using a file explorer, go to the Oxygen XML Editor *[OXYGEN_INSTALL_DIR]*`/frameworks` directory. Select the `sdf` directory and make an archive from it. Move it to another Oxygen XML Editor installation (eventually on another computer). Extract it in the *[OXYGEN_INSTALL_DIR]*`/frameworks` directory. Start Oxygen XML Editor and test the association as explained above.

When deploying your customized `sdf` directory, make sure that your `sdf` directory contains the `sdf.framework` file (that is the file defined as External Storage in the ***Document Type Association*** *preferences page* shall always be stored inside the `sdf` directory). If your external storage points somewhere else Oxygen XML Editor will not be able to update the *Document Type Association* options automatically on the deployed computers.

Adding/Editing a Framework (Document Type)

To add or edit a *framework* (document type), *open the **Preferences** dialog box **(Options > Preferences)*** and go to **Document Type Association**. From this ***Document Type Association** preferences page* you can use the **New**, **Edit**, **Duplicate**, or **Extend** buttons to open a ***Document Type** configuration dialog box* that allows you to customize a new or existing document type (*framework*).

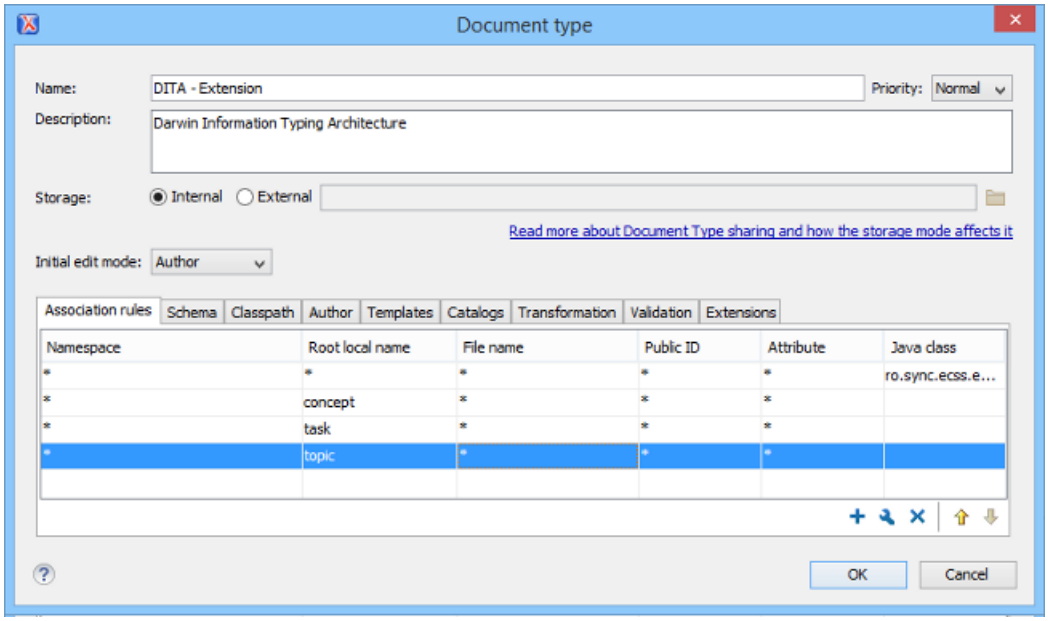

Figure 704: Document Type Configuration Dialog Box

You can specify the following properties for a document type:

- **Name** - The name of the document type.
- **Priority** - When multiple document types match the same document, the priority determines the order in which they are applied. It can be one of the following: Lowest, Low, Normal, High, Highest. The predefined document types that are already configured when the application is installed on the computer have the default Low priority.

  Note: *Frameworks* that have the same priority are sorted alphabetically.
- **Description** - The document type description displayed as a tool tip in the ***Document Type Association** preferences page*.
- **Storage** - The location where the document type is saved. If you select the **External** storage option, the document type is saved in the specified file with a mandatory `framework` extension, located in a subdirectory of the current `frameworks` directory. If you select the **Internal** storage option, the document type data is saved in the Oxygen XML Editor internal options file if *Global Options* is selected or in the current Oxygen XML Editor project file (`.xpr`) if *Project Options* is selected.
- **Initial edit mode** - Allows you to select the initial editing mode for this document type: **Editor specific**, **Text**, **Author, Grid** and **Design** (available only for the W3C XML Schema editor). If the **Editor specific** option is selected, the initial editing mode is determined based upon the editor type. You can find the mapping between editors and edit modes in the ***Edit modes** preferences page*. You can impose an initial mode for opening files that match the association rules of the document type. For example, if the files are usually edited in the **Author** mode you can set it in the **Initial edit mode** combo box.

Note: You can also customize the initial mode for a document type in the **Edit modes** preferences page. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Editor** > **Edit modes**.

You can specify the **Association rules** used for determining a document type for an opened XML document. A rule can define one or more conditions. All conditions need to be fulfilled for a specific rule to be chosen. Conditions can specify:

- **Namespace** - The namespace of the document that matches the document type.
- **Root local name of document** - The local name of the document that matches the document type.

- **File name** - The file name (including the extension) of the document that matches the document type.
- **Public ID** (for DTDs) - The PUBLIC identifier of the document that matches the document type.
- **Attribute** - This field allows you to associate a document type depending on a certain value of the attribute in the root.
- **Java class** - Name of the Java class that is called to determine if the document type should be used for an XML document. Java class must either implement the *ro.sync.ecss.extensions.api.DocumentTypeCustomRuleMatcher* interface or extend the *ro.sync.ecss.extensions.api.DocumentTypeAdvancedCustomRuleMatcher* abstract class from the *Author API*.

In the **Schema** tab, you can specify the type and URI of schema used for validation and content completion of all documents from the document type, when there is no schema detected in the document.

You can choose one of the following schema types:

- DTD
- Relax NG schema (XML syntax)
- Relax NG schema (XML syntax) + Schematron
- Relax NG schema (compact syntax)
- XML Schema
- XML Schema + Schematron rules
- NVDL schema

Configuring and Managing Multiple CSS Styles on page 1473
Customizing the Main CSS of a Framework on page 1454

Configure Actions, Menus, and Toolbars for a Framework

You can configure actions, menus, and toolbars that are specific to a *framework* (document type) in the **Author** mode to gain a productive editing experience, by using the ***Document Type*** *configuration dialog box*.

To add or configure actions, menus, or toolbars follow this procedure:

1. *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)***, go to **Document Types Association**, and select the *framework* for which you want to create an action.
2. Click **Edit** and in the ***Document Type*** *configuration dialog box* go to the **Author** tab, then go to **Actions**.
3. Click the **New** button and use the ***Action*** *dialog box* to create an action.

Configure the Insert Section Action for a Framework

This topic describes the procedure for defining the **Insert Section** action for a custom *framework*. It is assumed that the icon files,  (`Section16.gif`) for the menu item and  (`Section20.gif`) for the toolbar, are already available. Although you could use the same icon size for both the menu and toolbar, usually the icons from the toolbars are larger than the ones found in the menus. These files should be placed in your custom *framework* directory (*`[OXYGEN_INSTALL_DIR]`*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).

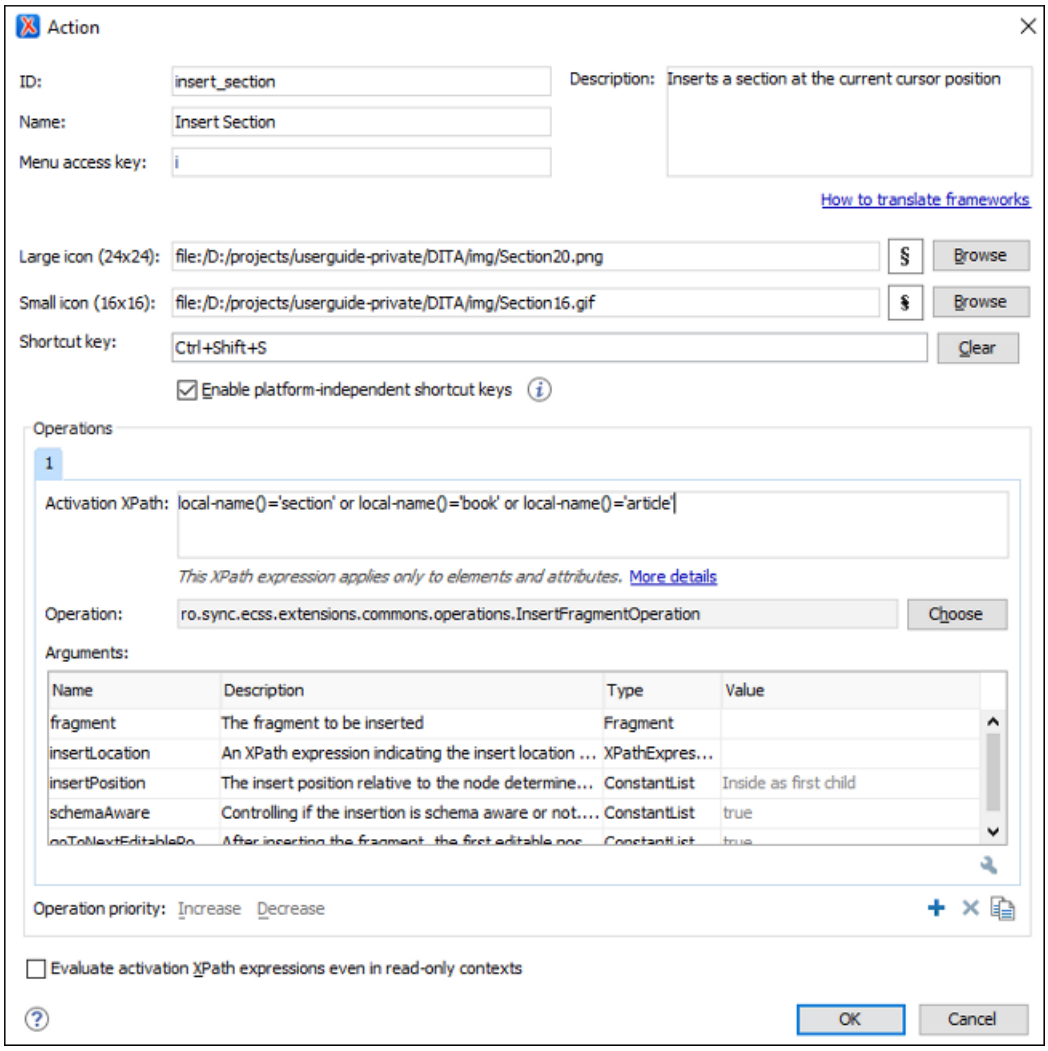

Figure 705: Action Dialog Box

1. Set the **ID** field to **insert_section**. This is a unique action identifier.
2. Set the **Name** field to **Insert Section**. This will be the action's name, displayed as a tooltip when the action is placed in the toolbar, or as the menu item name.
3. Set the **Menu access key** to **i**. On Windows, the menu items can be accessed using **Alt+letter** keys combination, when the menu is visible. The letter is visually represented by underlining the first letter from the menu item name having the same value.
4. Add a **Description**.
5. Set the **Large icon (20x20)** field to `${frameworks}/sdf/Section20.gif`. A good practice is to store the image files inside the *framework* directory and use *editor variable* **${framework}** to make the image relative to the *framework* location.

   If the images are bundled in a *JAR* archive together with some Java operations implementation, for instance, it might be convenient for you to reference the images not by the file name, but by their relative path location in the class-path.

   If the image file `Section20.gif` is located in the **images** directory inside the *JAR* archive, you can reference it by using **/images/Section20.gif**. The *JAR* file must be added into the **Classpath** list.
6. Set the **Small icon (16x16)** field to `${frameworks}/sdf/Section16.gif`.
7. Click the text field next to **Shortcut key** and set it to **Ctrl+Shift+S (Meta+Shift+S on Mac OS)**. This will be the key combination to trigger the action using the keyboard only.

   The shortcut is enabled only by *adding the action to the main menu of **Author** mode*, which contains all the actions that the author will have in a menu for the current document type.

8. At this time the action has no functionality added to it. Next you must define how this action operates. An action can have multiple operation modes. The first action mode enabled by the evaluation of its associated XPath expression will be executed when the action is triggered by the user. The Xpath expression needs to be version 2.0 and its scope must be only element and attribute nodes of the edited document. Otherwise, the expression will not return a match and will not trigger the action. If the expression is left empty, the action will be enabled anywhere in the scope of the root element. For this example we'll suppose you want allow the action to add a section only if the current element is either a `book`, `article` or another `section`.
   a) Set the XPath expression field to:

   ```
   local-name()='section' or local-name()='book' or
    local-name()='article'
   ```

   b) Set the **invoke operation** field to *InsertFragmentOperation* built-in operation, designed to insert an XML fragment at cursor position. This belongs to a set of built-in operations, a complete list of which can be found in the *Author Default Operations* section. This set can be expanded with your own Java operation implementations.
   c) Configure the arguments section as follows:

   ```
   <section xmlns=
   "http://www.oxygenxml.com/sample/documentation">
        <title/>
   </section>
   ```

   `insertLocation` - leave it empty. This means the location will be at the cursor position.

   `insertPosition` - select "**Inside**".

Configure the Insert Table Action for a Framework

This topic describes the procedure for defining the **Insert Table** action for a custom *framework*. Suppose that you want to create an action that inserts a table with three rows and three columns into a document and the first row is the table header. As with *the insert section action*, you will use the *InsertFragmentOperation* built-in operation.

Place the icon files for the menu item, and for the toolbar, in your custom *framework* directory (*`[OXYGEN_INSTALL_DIR]`*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).

1. Set **ID** field to **insert_table**.
2. Set **Name** field to **Insert table**.
3. Set **Menu access key** field to **t**.
4. Set **Description** field to **Adds a table element**.
5. Set **Toolbar icon** to **${framework} / toolbarIcon.png**.
6. Set **Menu icon** to **${framework} / menuIcon.png**.
7. Set **Shortcut key** to **Ctrl + Shift + T (Command + Shift + T on OS X)**.
8. Set up the action's functionality:
   a) Set **XPath expression** field to `true()`.

   `true()` is equivalent with leaving this field empty.
   b) Set **Invoke operation** to use **InsertFragmentOperation** built-in operation that inserts an XML fragment to the cursor position.
   c) Configure operation's arguments as follows:

   fragment - set it to:

   ```
   <table xmlns=
   "http://www.oxygenxml.com/sample/documentation">
     <header><td/><td/><td/></header>
     <tr><td/><td/><td/></tr>
     <tr><td/><td/><td/></tr>
   </table>
   ```

   `insertLocation` - to add tables at the end of the section use the following code:

   ```
   ancestor::section/*[last()]
   ```

   `insertPosition` - Select **After**.

Configure the Main Menu for a Framework

Defined actions can be grouped into customized menus in the Oxygen XML Editor menu bar.

1. Open the ***Document Type*** *configuration dialog box*, select your custom *framework*, and go to the **Author** tab.
2. Go to the **Menu** subtab. In the left side you have the list of actions and some special entries:
   - **Submenu** - Creates a submenu. You can nest an unlimited number of menus.
   - **Separator** - Creates a separator into a menu. This way you can logically separate the menu entries.
3. The right side of the panel displays the current actions for that menu tree. To change its name, click this label to select it, then press the **Edit** button.
4. Select the **Submenu** label in the left panel section and the appropriate label in the right panel section, then press the **Add as child** button. Change the submenu name to **Table**, using the **Edit** button.
5. Select the **Insert section** action in the left panel section and the **Table** label in the right panel section, then press the **Add as sibling** button.
6. Now select the **Insert table** action in the left panel section and the **Table** in the right panel section. Press the **Add as child** button.

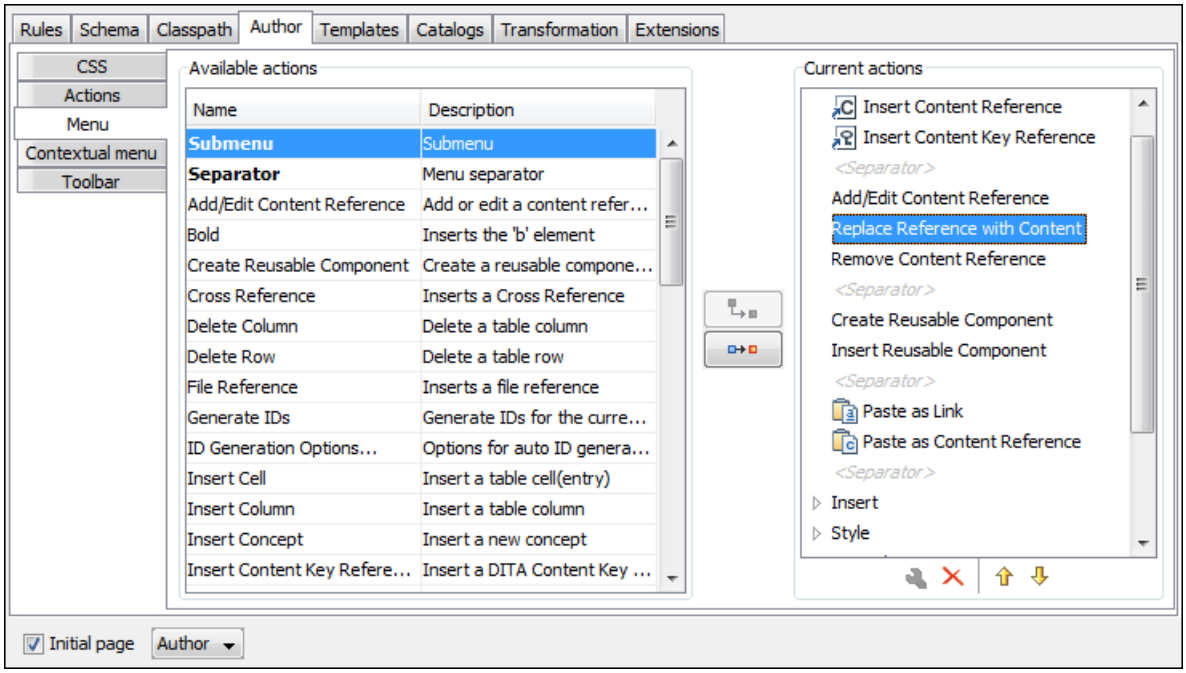

Figure 706: Configuring the Menu

When opening a test document for a custom *framework* in **Author** mode, the menu you created is displayed in the editor menu bar, between the **Tools** and the **Document** menus. The upper part of the menu contains generic **Author** mode actions (common to all document types) and the two actions created previously (with **Insert table** under the **Table** submenu).

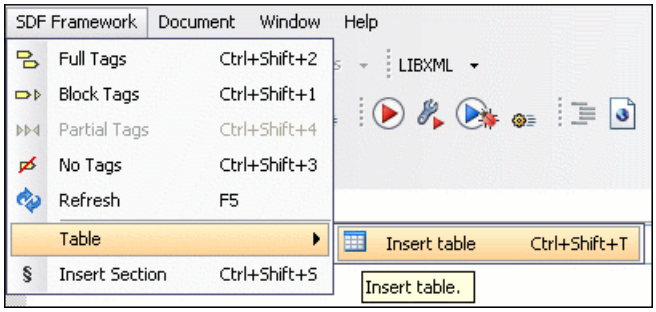

Figure 707: Author Mode Menu

Configure the Contextual Menu for a Framework

The contextual menu is displayed when you right-click in the **Author** editing area. You can only configure the bottom part of the menu, since the top part is reserved for a list of generic actions (such as Copy, Paste, Undo, etc.)

1. Open the ***Document Type*** *configuration dialog box* for the particular *framework* and go to the **Author** tab. Next, go to the **Contextual Menu** subtab.
2. Follow the same steps as explained in the *Configuring the Main Menu*, except changing the menu name because the contextual menu does not have a name.

   Note: You can choose to reuse a submenu that contains general authoring actions. In this case, all actions (both general and *framework*-specific ones) are grouped together under the same submenu.

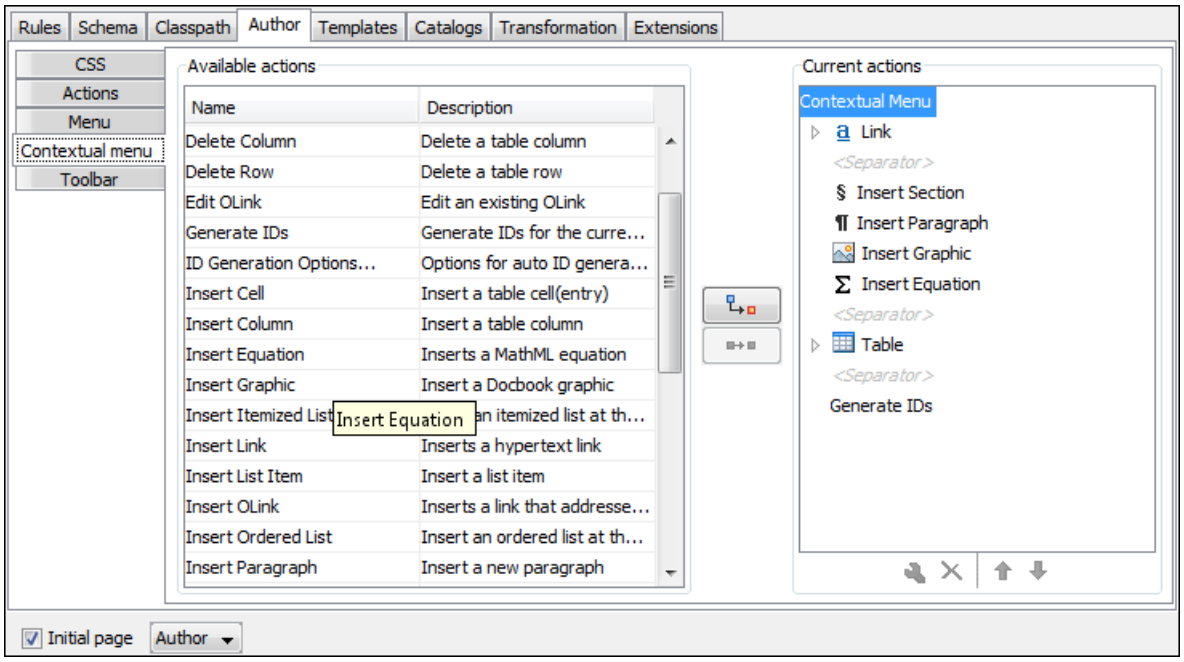

Figure 708: Configuring the Contextual Menu

To test it, open the test file, and open the contextual menu. In the lower part there is shown the **Table** sub-menu and the **Insert section** action.

Configure the Toolbars for a Framework

The procedure below describes how to add defined actions to a toolbar for a custom *framework*. These steps use examples from the two previous help topics that described how to define the ***Insert Section*** and ***Insert Table*** actions. You can also configure additional toolbars to add other custom actions.

1. Open the ***Document Type*** *configuration dialog box* for your custom *framework* and select the **Author** tab. Next, go to the **Toolbar** subtab.

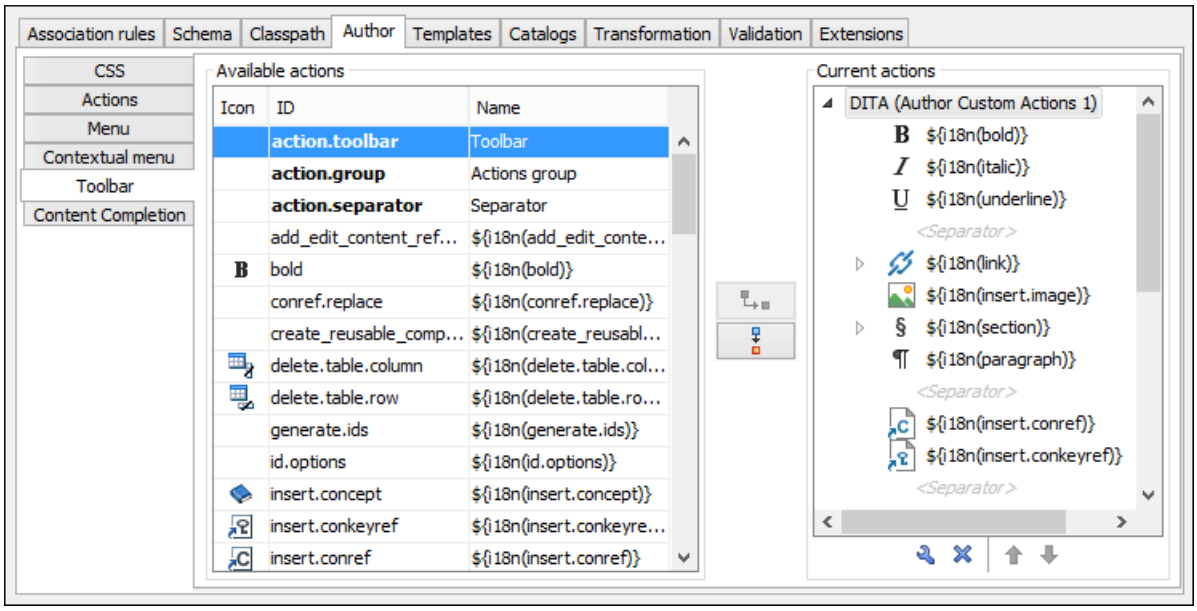

Figure 709: Configuring the Toolbar

The panel is divided in two sections: the left side contains a list of actions, while the right one contains an action tree, displaying the list of actions added in the toolbar. The special entry called *Separator* allows you to visually separate the actions in the toolbar.

2. Select the **Insert section** action in the left panel section and the **Toolbar** label in the right panel section, then press the **Add as child** button.
3. Select the **Insert table** action in the left panel section and the **Insert section** in the right panel section. Press the **Add as sibling** button.
   When opening a document of the particular *framework* in **Author** mode, the toolbar with the new buttons will be displayed in the toolbar area.

   Tip: If you have many custom toolbar actions, or want to group actions according to their category, add more toolbars with custom names and split the actions to better suit your purpose. If your toolbar is not displayed when switching to the **Author** mode, right-click the main toolbar, select **Configure Toolbars**, and make sure the appropriate toolbar (such as the **Author Custom Actions** toolbar) is selected.

Configure Content Completion for a Framework

You can customize the content of the following **Author** controls, adding items (which, when invoked, perform custom actions) or filtering the default contributed ones:

- *Content Completion Assistant* window
- ***Elements** view*
- **Insert Element** menus (from the ***Outline** view* or *breadcrumb* contextual menus)

You can use the content completion customization support in a custom *framework* by following this procedure:

1. Open the ***Document type** configuration dialog box* for your custom *framework* and select the **Author** tab. Next, go to the **Content Completion** tab.

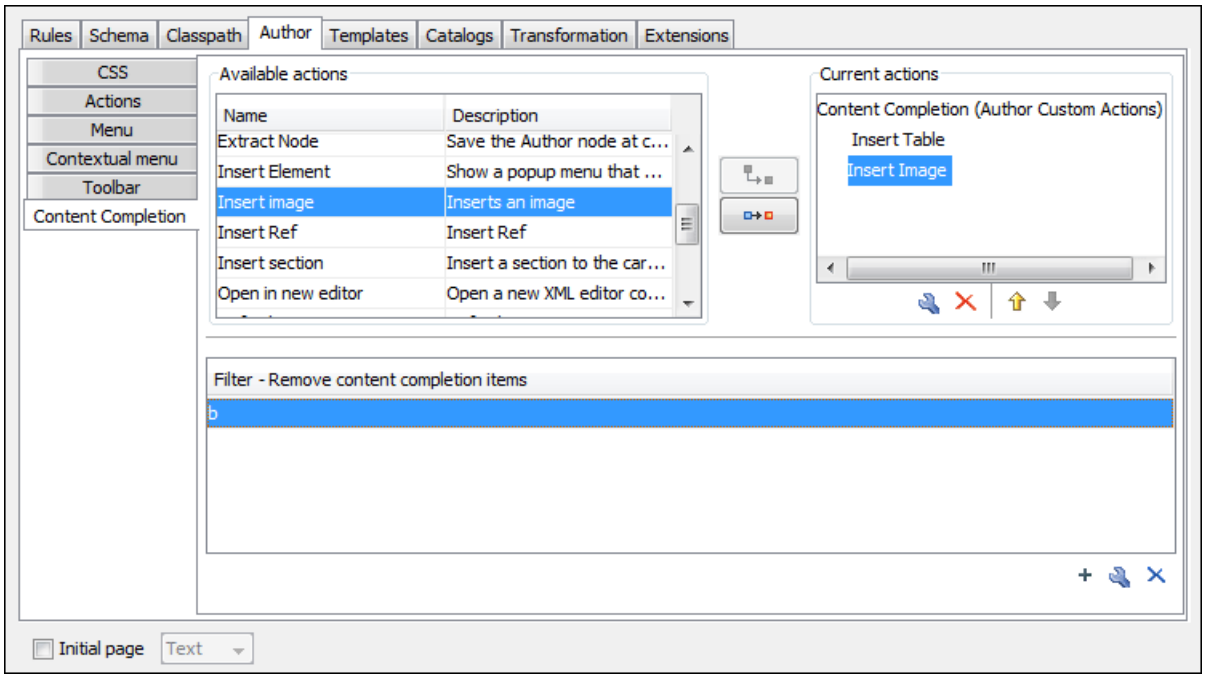

Figure 710: Customize Content Completion

The top side of the **Content Completion** section contains the list with all the actions defined within the custom *framework* and the list of actions that you decided to include in the *Content Completion Assistant* list of proposals. The bottom side contains the list with all the items that you decided to remove from the *Content Completion Assistant* list of proposals.

2. If you want to add a custom action to the list of current **Content Completion** proposals, select the action item from the **Available actions** list and press the **Add as child** or **Add as sibling** button to include it in the **Current actions** list. An **Insert Action** dialog box appears, giving you the possibility to select where to provide the selected action.

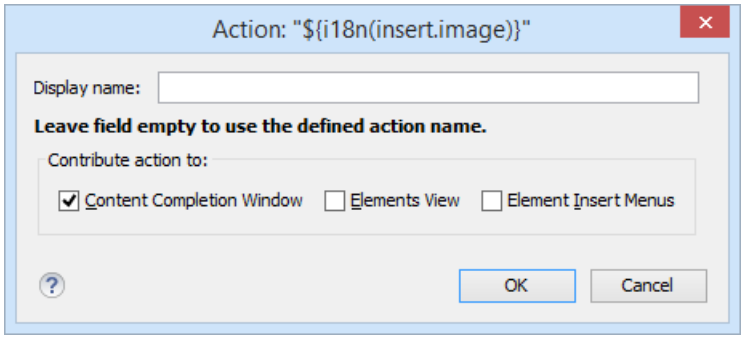

Figure 711: Insert Action Dialog Box

3. If you want to exclude a certain item from the **Content Completion** proposals, you can use the **Add** button from the **Filter - Remove content completion items** list. The **Remove item** dialog box is displayed, allowing you to input the item name and to choose the controls that filter it. The **Item name** combo box accepts wildcards.

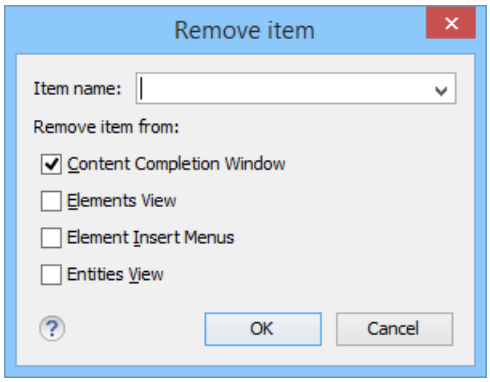

Figure 712: Remove Item Dialog Box

Author Mode Default Operations

The default operations for the **Author** mode, along with their arguments are as follows:

- **ChangeAttributeOperation**

  This operation allows you to add/modify/remove an attribute. You can use this operation in your own custom **Author** mode action to modify the value for a certain attribute on a specific XML element. The arguments of the operation are:

  - **name** - The attribute local name.
  - **namespace** - The attribute namespace.
  - **elementLocation** - The XPath location that identifies the element.
  - **value** - The new value for the attribute. If empty or null the attribute will be removed.
  - **editAttribute** - If an in-place editor exists for this attribute, it will automatically activate the in-place editor and start editing.
  - **removeIfEmpty** - The possible values are `true` and `false`. True means that the attribute should be removed if an empty value is provided. The default behavior is to remove it.
- **ChangePseudoClassesOperation**

  Operation that sets a list of pseudo-class values to nodes identified by an XPath expression. It can also remove a list of values from nodes identified by an XPath expression. The operation accepts the following parameters:

  - **setLocations** - An XPath expression indicating a list of nodes for which the specified list of pseudo-classes will be set. If it is not defined, then the element at the cursor position will be used.
  - **setPseudoClassNames** - A space-separated list of pseudo-class names that will be set on the matched nodes.
  - **removeLocations** - An XPath expression indicating a list of nodes from which the specified list of pseudo-classes will be removed. If it is not defined, then the element at the cursor position will be used.
  - **removePseudoClassNames** - A space-separated list of pseudo-class names that will be removed from the matched nodes.
  - **includeAllNodes** - The possible values are `yes` and no. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to no, they are ignored.
- **DeleteElementOperation**

  Deletes the node indicated by the `elementLocation` parameter XPath expression. If missing, the operation will delete the node at the cursor location.
- **DeleteElementsOperation**

  Deletes the nodes indicated by the `elementLocations` parameter XPath expression. If missing, the operation will delete the node at the cursor location.
- **ExecuteCommandLineOperation**

  This operation allows you to start a process executing a given command line. It has the following arguments:

- **name** - The name of the operation (or name of the console panel that corresponds to the process run by an action built over this operation).
- **workingDirectory** - The path to the directory where the command line is executed. The default value is `"."` (current directory).
- **cmdLine** - The command line to be executed (accepts *editor variables*).
- **showConsole** - If set to `true`, the console panel will be displayed in Oxygen XML Editor. The default value is `false`.

- **ExecuteMultipleActionsOperation**

  This operation allows the execution of a sequence of actions, defined as a list of action IDs. The actions must be defined by the corresponding *framework*, or one of the common actions for all *frameworks* supplied by Oxygen XML Editor.

  - **actionIDs** - The action IDs list that will be executed in sequence, the list must be a string sequence containing the IDs separated by commas or new lines.
- **ExecuteMultipleWebappCompatibleActionsOperation**

  An implementation of an operation that runs a sequence of Oxygen XML Web Author-compatible actions, defined as a list of IDs.
- **ExecuteTransformationScenariosOperation**

  This operation allows running one or more transformation scenarios defined in the current *document type association*. It is useful to add to the toolbar buttons that trigger publishing to various output formats. The argument of the operation is:

  - **scenarioNames** - The list of scenario names that will be executed, separated by new lines.
- **InsertEquationOperation**

  Inserts a fragment containing a MathML equation at the cursor offset. The argument of this operation is:

  - **fragment** - The XML fragment containing the MathML content that should be inserted.
- **InsertFragmentOperation**

  Inserts an XML fragment at the current cursor position. The selection - if there is one, remains unchanged. The fragment will be inserted in the current context of the cursor position meaning that if the current XML document uses some namespace declarations then the inserted fragment must use the same declarations. The namespace declarations of the inserted fragment will be adapted to the existing namespace declarations of the XML document. For more details about its list of parameters, see *Arguments of InsertFragmentOperation Operation* on page 1410.
- **InsertOrReplaceFragmentOperation**

  Similar to **InsertFragmentOperation**, except it removes the selected content before inserting the fragment. For more details about its list of parameters, see *Arguments of InsertFragmentOperation Operation*.
- **InsertOrReplaceTextOperation**

  Inserts a text at current position removing the selected content, if any. The argument of this operation is:

  - **text** - The text section to insert.
- **InsertXIncludeOperation**

  Insert an `XInclude` element at the cursor offset. Opens a dialog box that allows you to browse and select content to be included in your document and automatically generates the corresponding XInclude instruction.
- **JSOperation**

  Allows you to call the Java API from custom JavaScript content. For some sample **JSOperation** implementations, see *https://github.com/oxygenxml/javascript-sample-operations*.

  Notice: For the Oxygen XML Web Author, this operation cannot be invoked using the JavaScript API.

  This operation accepts the following parameter:

  - **script**

The JavaScript content to execute. It must have a function called `doOperation()`, which can use the predefined `authorAccess` variable. The `authorAccess` variable has access to the entire *ro.sync.ecss.extensions.api.AuthorAccess* Java API.

The following example is a script that retrieves the current value of the **type** attribute on the current element, allows the end user to edit its new value and sets the new value in the document:

```
function doOperation(){
 //The current node is either entirely selected...
 currentNode = authorAccess.getEditorAccess().getFullySelectedNode();
 if(currentNode == null){
 //or the cursor is placed in it
 caretOffset = authorAccess.getEditorAccess().getCaretOffset();
 currentNode = authorAccess.getDocumentController().getNodeAtOffset
                          (caretOffset);
 }
 //Get current value of the @type attribute
  currentTypeValue = "";
  currentTypeValueAttr = currentNode.getAttribute("type");
  if(currentTypeValueAttr != null){
    currentTypeValue = currentTypeValueAttr.getValue();
  }
 //Ask user for new value for attribute.
 newTypeValue = javax.swing.JOptionPane.showInputDialog
                        ("Input @type value", currentTypeValue);
 if(newTypeValue != null){
   //Create and set the new attribute value for the @type attribute.
   attrValue = new Packages.ro.sync.ecss.extensions.api.node.AttrValue
                        (newTypeValue);
   authorAccess.getDocumentController().setAttribute
                        ("type", attrValue, currentNode);
 }
}
```

Tip: You can call functions defined inside a script called `commons.js` from your custom script content so that you can use that external script file as a library of functions. Note that this `commons.js` file must be placed in the root of the *framework* directory (for example, *`[OXYGEN_INSTALL_DIR]`*`/frameworks/dita/commons.js`) because that is the only location where Oxygen XML Editor will look for it.

- **MoveCaretOperation**

  Flexible operation for moving the cursor within a document and it is also capable of performing a selection. The operation accepts the following arguments:

  - **xpathLocation** - An XPath expression that identifies the node relative to where the cursor will be moved. If the expression identifies more than one node, only the first one will be taken into account.
  - **position** - The position relative to the node obtained from the XPath expression where the cursor will be moved. When also choosing to perform a selection, you can use the following possible values:
    - `Before` - Places the cursor at the beginning of the selection.
    - `Inside, at the beginning` - Places the cursor at the beginning of the selection.
    - `After` - Places the cursor at the end of the selection.
    - `Inside, at the end` - Places the cursor at the end of the selection.
  - **selection** - Specifies if the operation should select the element obtained from the XPath expression, its content, or nothing at all. The possible values of the argument are: `None`, `Element`, and `Content`.
- **MoveElementOperation**

  Flexible operation for moving an XML element to another location from the same document. XPath expressions are used to identify the source element and the target location. The operation takes the following parameters:

  - **sourceLocation** - XPath expression that identifies the content to be moved.
  - **deleteLocation** - XPath expression that identifies the node to be removed. This parameter is optional. If missing, the **sourceLocation** parameter will also identify the node to be deleted.
  - **surroundFragment** - A string representation of an XML fragment. The moved node will be wrapped in this string before moving it in the destination.
  - **targetLocation** - XPath expression that identifies the location where the node must be moved to.
  - **insertPosition** - Argument that indicates the insert position.
  - **moveOnlySourceContentNodes** - When `true`, only the content of the source element is moved.

- **processTrackedChangesForXpathLocations** - When nodes are located via an XPath expression and the nodes are deleted with *Change Tracking* enabled, they are considered as being present by default (thus, the *change tracking* is ignored). If you set this argument to `true` and *change tracking* is enabled, deleted nodes will be ignored when the XPath locations are computed (thus, the *change tracking* is NOT ignored).

- **OpenInSystemAppOperation**

  Opens a resource in the system application that is associated with the resource in the operating system. The arguments of this operation is:

  - **resourcePath** - An XPath expression that, when executed, returns the path of the resource to be opened. *Editor variables* are expanded in the value of this parameter, before the expression is executed.
  - **isUnparsedEntity** - Possible values are `true` or `false`. If the value is `true`, the value of the **resourcePath** argument is treated as the name of an unparsed entity.
- **RemovePseudoClassOperation**

  An operation that removes a pseudo-class from an element. Accepts the following parameters:

  - **name** - Name of the pseudo-class to be removed.
  - **includeAllNodes** - The possible values are `yes` and `no`. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to `no`, they are ignored.
  - **elementLocation** - The XPath location that identifies the element. Leave it empty for the current element. It can also identify multiple elements, in which case the pseudo class will be removed from all of them.

    Example:

    Suppose that there is a pseudo-class called `myClass` on the element `paragraph` and there are CSS styles matching the pseudo-class.

    ```
    paragraph:myClass{
      font-size:2em;
      color:red;
    }
    paragraph{
      color:blue;
    }
    ```

    In the previous example, by removing the pseudo-class, the layout of the `paragraph` is rebuilt by matching the other rules (in this case, the foreground color of the `paragraph` element will become blue.
- **RenameElementOperation**

  This operation allows you to rename all occurrences of the elements identified by an XPath expression. The operation requires two parameters:

  - **elementName** - The new element name
  - **elementLocation** - The XPath expression that identifies the element occurrences to be renamed. If this parameter is missing, the operation renames the element at current cursor position.
- **SetPseudoClassOperation**

  An operation that sets a pseudo-class to an element. The operation accepts the following parameters:

  - **elementLocation** - An XPath expression indicating the element for which the pseudo-class will be set. If it is not defined, then the element at cursor position will be used.
  - **name** - The pseudo-class local name.
  - **includeAllNodes** - The possible values are `yes` and `no`. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to `no`, they are ignored.
- **ShowElementDocumentationOperation**

  Opens the associated specification HTML page for the current element. The operation accepts as parameter a URL pattern that points to the HTML page containing the documentation.
- **SurroundWithFragmentOperation**

  Surrounds the selected content with a text fragment. Since the fragment can have multiple nodes, the surrounded content will be always placed in the first leaf element. If there is no selection, the operation will simply insert the fragment at the cursor position. For more details about the list of parameters go to *Arguments of SurroundWithFragmentOperation* on page 1412.

- **SurroundWithTextOperation**

  This operation has two arguments (two text values) that will be inserted before and after the selected content. If there is no selected content, the two sections will be inserted at the cursor position. The arguments of the operation are:

  - **header** - The text that is placed before the selection.
  - **footer** - The text that is placed after the selection.
- **TogglePseudoClassOperation**

  An implementation of an operation to toggle on/off the pseudo-class of an element. Accepts the following parameters:

  - **name** - Name of the pseudo-class to be toggled on/off.
  - **includeAllNodes** - The possible values are `yes` and no. If set to `yes`, comments, CDATA, and text nodes are included when evaluating XPath expressions. If set to no, they are ignored.
  - **elementLocation** - The XPath location that identifies one or more elements for which the pseudo class will be toggled. Leave it empty for the current element.

    Example:

    ```
    paragraph:myClass{
      color:red;
    }
    paragraph{
      color:blue;
    }
    ```

    By default, the paragraph content is rendered in blue. Suppose that we have a `TogglePseudoClassOperation` configured for the `myClass` pseudo-class. Invoking it the first time will set the `myClass` pseudo-class and the paragraph will be rendered in red. Invoking the operation again, will remove the pseudo-class and the visible result will be a blue rendered `paragraph` element.
- **ToggleSurroundWithElementOperation**

  This operation allows wrapping and unwrapping content in a specific wrapper element that can have certain attributes specified on it. It is useful to implement toggle actions such as highlighting text as bold, italic, or underline. The operation supports processing multiple selection intervals, such as multiple cells within a table column selection. The arguments of the operation are:

  - **element** - The element to wrap or unwrap content.
  - **schemaAware** - This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try to wrap a *paragraph* element with a *bold* element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.
- **UnwrapTagsOperation**

  This operation allows removing the element tags either from the current element or for an element identified with an XPath location. The argument of the operation is

  - **unwrapElementLocation** - An XPath expression indicating the element to unwrap. If it is not defined, the element at the cursor position is unwrapped.
- **XQueryUpdateOperation**

  Allows you to execute an XQuery Update script directly over content in **Author** mode.

  Notice: This operation is not applicable to the Oxygen XML Author Component or the Oxygen XML Web Author.

  It supports the following arguments:

  - **script** - The XQuery Update script to be executed. The value can either be an XQuery script or a URL that points to the XQuery Update script. You can use the *${framework}* or *${frameworkDir}* editor variables to refer the scripts from the *framework* directory.

The script will be executed in the context of the node at the cursor position. If the script declares the following variable, it will also receive the selected nodes (assuming that entire nodes are selected):

```
declare variable $oxyxq:selection external;
```

In the *example below*, you can see how this argument is used.

- **externalParams** - A string that can assign multiple key-value pairs separated by a comma or a new line character.

  For example, if an XQuery script declares two external parameters like this:

  ```
  declare variable $param1 external;
  declare variable $param2 external;
  ```

  You can pass custom values for each parameter by setting the `externalParams` to `param1=value1,param2=value2`.
- **expandXincludeReferences** - Makes all *Xinclude* elements transparent to the XQuery transformer. When the *Xinclude* references are transparent, the **XQueryUpdateOperation** can use the referenced elements for further processing in the current document, but it cannot change their values in the original document. The default value is `false`, which means the *Xinclude* elements are not transparent.

An example of an XQuery Update Script that converts paragraphs to list items:

```
declare namespace oxyxq = "http://www.oxygenxml.com/ns/xqu";
(: This variable will be linked to the selected nodes assuming that there are
actually fully selected nodes. For example this selection will return null:
<p>{SEL_START}text{SEL_END} in para</p>
but this will give two "p" elements:
{SEL_END}<p>text</p><p>text2</p>{SEL_END}

If a multiple selection exists it will also be processed and forwarded.
 Again, only fully selected nodes will be passed.
:)
declare variable $oxyxq:selection external;

(: We will process either the selection or the context node :)
let $toProcess := if (empty($oxyxq:selection)) then
    (.)
else
    ($oxyxq:selection)

returnif (not(empty($toProcess))) then
        (
        (: Create the list :)
        let $ul :=
        <ul>
            {
                for $sel in $toProcess
                return
                    <li>{$sel}</li>
            }
        </ul>

        return
            (
            (: Delete the processed nodes :)
            for $sel in $toProcess
            return
                delete node $sel,
            (: Inserts the constructed list :)
            insert node $ul
                before $toProcess[1]
            )
        )
    else
        ()
```

- **XSLTOperation** and **XQueryOperation**

  Applies an XSLT or XQuery script on a source element and then replaces or inserts the result in a specified target element.

  Notice: For the Oxygen XML Web Author, these operations cannot be invoked using the *JavaScript API*.

  These operations have the following parameters:

  - **sourceLocation**

An XPath expression indicating the element that the script will be applied on. If it is not defined, then the element at the cursor position will be used.

There may be situations in which you want to look at an ancestor of the current element and take decisions in the script based on this. To do this, you can set the **sourceLocation** to point to an ancestor node then declare a parameter called **currentElementLocation** in your script and use it to re-position in the current element, as in the following example:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform" version="2.0"
  xpath-default-namespace="http://docbook.org/ns/docbook"
  xmlns:saxon="http://saxon.sf.net/" exclude-result-prefixes="saxon">
    <!-- This is an XPath location to be sent by the operation to the script -->
    <xsl:param name="currentElementLocation"/>

    <xsl:template match="/">
        <!-- Evaluate the XPath of the current element location -->
        <xsl:apply-templates
        select="saxon:eval(saxon:expression($currentElementLocation))"/>
    </xsl:template>

    <xsl:template match="para">
        <!-- And the context is again inside the current element,
        but we can use information from the entire XML -->
        <xsl:variable
            name="keyImage" select="//imagedata[@fileref='images/lake.jpeg']
              /ancestor::inlinemediaobject/@xml:id/string()"/>
                <xref linkend="{$keyImage}" role="key_include"
                  xmlns="http://docbook.org/ns/docbook">
                    <xsl:value-of
                          select="$currentElementLocation"></xsl:value-of>
        </xref>
    </xsl:template>
</xsl:stylesheet>
```

- **targetLocation**

  An XPath expression indicating the insert location for the result of the transformation. If it is not defined then the insert location will be at the cursor location.
- **script**

  The script content (XSLT or XQuery). The base system ID for this will be the *framework* file, so any include/import reference will be resolved relative to the `.framework` file that contains this action definition.

  For example, for the following script, the imported `xslt_operation.xsl` needs to be located in the current *framework* directory.

  ```
  <xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                  version="1.0">
      <xsl:import href="xslt_operation.xsl"/>
  </xsl:stylesheet>
  ```

  You can also use a path for an included or imported reference. When using a path, the following apply:

  - A relative path is resolved to the *framework* directory.
  - The *${framework} editor variable* can also be used to reference resources from the *framework* directory.
  - The path is passed through the catalog mappings. It helps to use an absolute URL (for instance, `http://www.oxygenxml.com/fr/testy.xsl`) and map it in the `catalog.xml` file from the *framework* directory to a resource from the *framework*.
- **action**

  The insert action relative to the node determined by the target XPath expression. It can be: Replace, At cursor position, Before, After, Inside as first child or Inside as last child.
- **caretPosition**

  The position of the cursor after the action is executed. It can be: `Preserve`, `Before`, `Start`, `First editable position`, `End`, or `After`. If this parameter is not set, you can still indicate the position of the cursor by using the *${caret} editor variable* in the inserted content.
- **expandEditorVariables**

  Parameter controlling the expansion of *editor variables* returned by the script processing. Expansion is enabled by default.
- **suspendTrackChanges**

It has 2 possible values (`true` and `false`). The default value is `false`. When set to `true`, the *Track Changes* feature is deactivated. When using this argument, after the action is finished, the state of the *Track Changes* feature is restored to its initial value.

XSLTOperation Example: Sort a list with respect to the language declared on the root element-

Suppose we want an action that will sort a list with respect to the language declared on the root element and we have an XML file like this:

```
<article xml:lang="en">
  <ul>
     <li>B</li>
     <li>C</li>
     <li>A</li>
  </ul>
</article>
```

The **XSLTOperation** needs to be configured as follows:

- **sourceLocation** is set to /* so that the script has access to the root element and its children.
- **targetLocation** is left untouched (assuming that the action is active only when the cursor is inside the list).

The XSLT script would look like this:

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:saxon="http://saxon.sf.net/"
  xmlns:lds="http://www.lds.org/schema/lds-meta/v1"
  xmlns:xs="http://www.w3.org/2001/XMLSchema"
  exclude-result-prefixes="xs saxon" version="2.0">

  <xsl:param name="currentElementLocation"/>

  <xsl:template match="/">
      <!--
          sourceLocation parameter was set to /* to have a larger context.
          We can pinpoint the element that contained the caret
          using $currentElementLocation
      -->
     <xsl:apply-templates select="saxon:eval(saxon:expression($currentElementLocation))"/>
  </xsl:template>

  <xsl:template match="ul">

    <!-- Because the sourceLocation parameter was set to /* we now have access to
         the root element and its attributes. -->
    <xsl:variable name="lang" select="/*/@xml:lang"/>
    <xsl:variable name="collationURI">
      <xsl:value-of select="concat('http://www.w3.org/2013/collation/UCA?lang=', $lang)"/>
    </xsl:variable>

      <xsl:copy>
          <xsl:copy-of select="@*"/>

          <!-- Copy the list items, but sorted. -->
          <xsl:apply-templates select="li">
              <xsl:sort collation="{$collationURI}" select="text()"/>
          </xsl:apply-templates>
      </xsl:copy>
  </xsl:template>

  <!-- This copy template will handle the contents of the list items. -->
  <xsl:template match="@* | node()">
      <xsl:copy>
          <xsl:apply-templates select="@* | node()"/>
      </xsl:copy>
  </xsl:template>
</xsl:stylesheet>
```

Editor Variables in Author Mode Operations

Author mode operations can include parameters that contain the following *editor variables*:

- **${caret}** - The position where the cursor is located. This variable can be used in a code template, in **Author** mode operations, or in a **selection** *plugin*.

Note: The **${caret}** editor variable is available only for parameters that take XML content as values. It is replaced with the **${UNIQUE_CARET_MARKER_FOR_AUTHOR}** macro. The default Author operations process this macro and position the cursor at the designated offset.

- **${selection}** - The current selected text content in the current edited document. This variable can be used in a code template, in **Author** mode operations, or in a **selection** *plugin*.
- **${ask('message', type, ('real_value1':'rendered_value1'; 'real_value2':'rendered_value2'; ...), 'default_value')}** - To prompt for values at runtime, use the *ask('message', type, ('real_value1':'rendered_value1'; 'real_value2':'rendered_value2'; ...), 'default-value")* editor variable. You can set the following parameters:
  - **'message'** - The displayed message. Note the quotes that enclose the message.
  - **type** - Optional parameter, with one of the following values:

    Note: The title of the dialog box will be determined by the type of parameter and as follows:

    - For *url* and *relative_url* parameters, the title will be the name of the parameter and the value of the *'message'*.
    - For the other parameters listed below, the title will be the name of that respective parameter.
    - If no parameter is used, the title will be "Input".

Parameter	
url	**Format:** *${ask('message', url, 'default_value')}*
	Description: Input is considered a URL. Oxygen XML Editor checks that the provided URL is valid.
	Example: • *${ask('Input URL', url)}* - The displayed dialog box has the name *Input URL*. The expected input type is URL. • *${ask('Input URL', url, 'http://www.example.com')}* - The displayed dialog box has the name *Input URL*. The expected input type is URL. The input field displays the default value *http://www.example.com*.
password	**Format**: *${ask('message', password, 'default')}*
	Description: The input is hidden with bullet characters.
	Example: • *${ask('Input password', password)}* - The displayed dialog box has the name *'Input password'* and the input is hidden with bullet symbols. • *${ask('Input password', password, 'abcd')}* - The displayed dialog box has the name *'Input password'* and the input hidden with bullet symbols. The input field already contains the default **abcd** value.
generic	**Format**: *${ask('message', generic, 'default')}*
	Description: The input is considered to be generic text that requires no special handling.
	Example: • *${ask('Hello world!')}* - The dialog box has a *Hello world!* message displayed. • *${ask('Hello world!', generic, 'Hello again!')}* - The dialog box has a *Hello world!* message displayed and the value displayed in the input box is *'Hello again!'*.
relative_url	**Format:** *${ask('message', relative_url, 'default')}*
	Description: Input is considered a URL. Oxygen XML Editor tries to make the URL relative to that of the document you are editing. **Note:** If the *$ask* editor variable is expanded in content that is not yet saved (such as an *untitled* file, whose path cannot be determined), then Oxygen XML Editor will transform it into an absolute URL.

Parameter	
	Example: • *${ask('File location', relative_url, 'C:/example.txt')}* - The dialog box has the name *'File location'*. The URL inserted in the input box is made relative to the current edited document location.
combobox	**Format:** *${ask('message', combobox, ('real_value1':'rendered_value1';...;'real_valueN':'rendered_valueN'), 'default')}*
	Description: Displays a dialog box that offers a drop-down menu. The drop-down menu is populated with the given *rendered_value* values. Choosing such a value will return its associated value (*real_value*). **Note:** The *'default'* parameter specifies the default selected value and can match either a key or a value.
	Example: • *${ask('Operating System', combobox, ('win':'Microsoft Windows';'osx':'Mac OS X';'lnx':'Linux/UNIX'), 'osx')}* - The dialog box has the name *'Operating System'*. The drop-down menu displays the three given operating systems. The associated value will be returned based upon your selection. **Note:** In this example, the default value is indicated by the *osx* key. However, the same result could be obtained if the default value is indicated by *Mac OS X*, as in the following example: *${ask('Operating System', combobox, ('win':'Microsoft Windows';'osx':'Mac OS X';'lnx':'Linux/UNIX'), 'Mac OS X')}* • *${ask('Mobile OS', combobox, ('win':'Windows Mobile';'ios':'iOS';'and':'Android'), 'Android')}*
editable_combobox	**Format:** *${ask('message', editable_combobox, ('real_value1':'rendered_value1';...;'real_valueN':'rendered_valueN'), 'default')}*
	Description: Displays a dialog box that offers a drop-down menu with editable elements. The drop-down menu is populated with the given *rendered_value* values. Choosing such a value will return its associated real value (*real_value*) or the value inserted when you edit a list entry. **Note:** The *'default'* parameter specifies the default selected value and can match either a key or a value.
	Example: • *${ask('Operating System', editable_combobox, ('win':'Microsoft Windows';'osx':'Mac OS X';'lnx':'Linux/UNIX'), 'osx')}* - The dialog box has the name *'Operating System'*. The drop-down menu displays the three given operating systems and also allows you to edit the entry. The associated value will be returned based upon your selection or the text you input.
radio	**Format:** *${ask('message', radio, ('real_value1':'rendered_value1';...;'real_valueN':'rendered_valueN'), 'default')}*

Parameter	
	Description: Displays a dialog box that offers a series of radio buttons. Each radio button displays a *'rendered_value* and will return an associated *real_value*. **Note:** The *'default'* parameter specifies the default selected value and can match either a key or a value.
	Example: • *${ask('Operating System', radio, ('win':'Microsoft Windows';'osx':'Mac OS X';'lnx':'Linux/UNIX'), 'osx')}* - The dialog box has the name *'Operating System'*. The radio button group allows you to choose between the three operating systems. **Note:** In this example `Mac OS X` is the default selected value and if selected it would return *osx* for the output.

  - 'default-value' - optional parameter. Provides a default value.
- **${timeStamp}** - Time stamp, that is the current time in Unix format. For example, it can be used to save transformation results in multiple output files on each transformation.
- **${uuid}** - Universally unique identifier, a unique sequence of 32 hexadecimal digits generated by the Java *UUID* class.
- **${id}** - Application-level unique identifier. It is a short sequence of 10-12 letters and digits that is not guaranteed to be universally unique.
- **${cfn}** - Current file name without extension and without parent folder. The current file is the one currently opened and selected.
- **${cfne}** - Current file name with extension. The current file is the one currently opened and selected.
- **${cf}** - Current file as file path, that is the absolute file path of the current edited document.
- **${cfd}** - Current file folder as file path, that is the path of the current edited document up to the name of the parent folder.
- **${frameworksDir}** - The path (as file path) of the *[OXYGEN_INSTALL_DIR]*`/frameworks` directory.
- **${pd}** - The file path to the folder that contains the current project file (`.xpr`).
- **${oxygenInstallDir}** - Oxygen XML Editor installation folder as file path.
- **${homeDir}** - The path (as file path) of the user home folder.
- **${pn}** - Current project name.
- **${env(VAR_NAME)}** - Value of the *VAR_NAME* environment variable. The environment variables are managed by the operating system. If you are looking for Java System Properties, use the **${system(var.name)}** editor variable.
- **${system(var.name)}** - Value of the *var.name* Java System Property. The Java system properties can be specified in the command line arguments of the Java runtime as *-Dvar.name=var.value*. If you are looking for operating system environment variables, use the **${env(VAR_NAME)}** editor variable instead.
- **${date(pattern)}** - Current date. The allowed patterns are equivalent to the ones in the *Java SimpleDateFormat class*. **Example:** *yyyy-MM-dd*;

  Note: This editor variable supports both the xs:date and xs:datetime parameters. For details about xs:date, go to *http://www.w3.org/TR/xmlschema-2/#date*. For details about xs:datetime, go to *http://www.w3.org/TR/xmlschema-2/#dateTime*.

Arguments of InsertFragmentOperation Operation

Arguments of SurroundWithFragmentOperation

Arguments of `InsertFragmentOperation` Operation

fragment

This argument has a textual value. This value is parsed by Oxygen XML Editor as it was already in the document at the cursor position. You can use entity references declared in the document and it is namespace aware. The fragment may have multiple roots.

You can even use namespace prefixes that are not declared in the inserted fragment, if they are declared in the document where the insertion is done. For the sake of clarity, you should always prefix and declare namespaces in the inserted fragment!

If the fragment contains namespace declarations that are identical to those found in the document, the namespace declaration attributes will be removed from elements contained by the inserted fragment.

There are two possible scenarios:

1. **Prefixes that are not bound explicitly**

   For instance, the fragment:

   ```
   <x:item id="dty2"/>
   &ent;
   <x:item id="dty3"/>
   ```

   Can be correctly inserted in the document: ('|' marks the insertion point):

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <!DOCTYPE x:root [
       <!ENTITY ent "entity">
   ]>

   <x:root xmlns:x="nsp">
     |
   </x:root>
   ```

   Result:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <!DOCTYPE x:root [
       <!ENTITY ent "entity">
   ]>
   <x:root xmlns:x="nsp">
       <x:item id="dty2"/>
       &ent;
       <x:item id="dty3"/>
   </x:root>
   ```

2. **Default namespaces**

If there is a default namespace declared in the document and the *document fragment* does not declare a namespace, the elements from the fragment are considered to be in **no namespace**.

For instance, the fragment:

```
<item id="dty2"/>
<item id="dty3"/>
```

Inserted in the document:

```
<?xml version="1.0" encoding="UTF-8"?>
<root xmlns="nsp">
|
</root>
```

Gives the result document:

```
<?xml version="1.0" encoding="UTF-8"?>
<root xmlns="nsp">
    <item xmlns="" id="dty2"/>
    <item xmlns="" id="dty3"/>
</root>
```

insertLocation

An XPath expression that is relative to the current node. It selects the reference node for the fragment insertion. When missing, the fragment will be inserted at the cursor position.

insertPosition

Specifies where the insertion is made relative to the reference node selected by the *insertLocation*. It can be one of the following constants:

- **Inside as first child** (default value) - The fragment is inserted as first child of the reference node.
- **Inside as last child** - The fragment is inserted as the last child of the reference node.
- **After** - The fragment is inserted after the reference node.
- **Before** - The fragment is inserted before the reference node.

goToNextEditablePosition

After inserting the fragment, the first editable position is detected and the cursor is placed at that location. It handles any in-place editors used to edit attributes. It will be ignored if the fragment specifies a cursor position using the ***${caret}*** *editor variable*. The possible values of this action are **true** and **false**.

schemaAware

This argument applies only on the surround with element operation and controls whether or not the insertion is valid, based upon the schema. If the insertion is not valid, then wrapping action will be broken up into smaller intervals until the wrapping action is valid. For example, if you try to wrap a *paragraph* element with a *bold* element, it would not be valid, so the operation will wrap the text inside the paragraph instead, since it would be valid at that position.

Arguments of *SurroundWithFragmentOperation*

The **Author** mode operation *SurroundWithFragmentOperation* has only one argument:

- fragment

  The XML fragment that will surround the selection. For example, consider the fragment:

```
<F>
   <A></A>
   <B>
     <C></C>
   </B>
</F>
```

  and the document:

```
<doc>
  <X></X>
  <Y></Y>
  <Z></Z>
<doc>
```

  Considering the selected content to be surrounded is the sequence of elements X and Y, then the result is:

```
<doc>
   <F>
      <A>
         <X></X>
         <Y></Y>
      </A>
      <B>
        <C></C>
      </B>
   </F>
  <Z></Z>
<doc>
```

  Since the element A was the first leaf in the fragment, it received the selected content. The fragment was then inserted in the place of the selection.

Add a Custom Operation to an Existing Framework

This task explains how to add a custom **Author** mode operation to an existing *framework* (document type).

1. Setup a sample project by following the *instructions for installing the SDK*. Our sample *framework* project is `oxygen-sample-framework`.

2. A variety of classes in the *simple.documentation.framework.operations* package implement the *ro.sync.ecss.extensions.api.AuthorOperation* interface. Depending on your use-case, modify one of these classes.
3. Pack the operation class inside a Java *JAR* library.
4. Copy the *JAR* library to your framework directory (for example, *[OXYGEN_INSTALL_DIR]*`/frameworks/[FRAMEWORK_DIR]`).
5. *Open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Document Type Association**, and edit the document type (you need write access to the *[OXYGEN_INSTALL_DIR]*) to open the ***Document Type** configuration dialog box*.
   a) In the **Classpath** tab, add a reference to your JAR library (for example, `${framework}/customAction.jar`).
   b) Go to the **Author** tab, then go to the **Actions** subtab.
   c) Click the **New** button and use the ***Action** dialog box* to create a new action that uses your custom operation.
   d) Mount the action to the toolbars or menus. You can also define a shortcut key.
6. *Share the modifications* with your colleagues. The files that should be shared are your `customAction.jar` library and the `.framework` configuration file from the *[OXYGEN_INSTALL_DIR]*`/frameworks/[FRAMEWORK_DIR]` directory.

AuthorOperation API

Adding Retina/HiDPI Icons in a Framework

Higher resolution icons can also be included in customized *frameworks* for rendering them in a Retina or HiDPI display. The icons can be referenced directly from the ***Document Type Congifuration** dialog box* (from the ***Action** dialog box*) or from an API (*ro.sync.exml.workspace.api.node.customizer.XMLNodeRendererCustomizer*).

As with any image, the higher resolution icons are stored in the same images folder as the normal resolution images and they are identified by a scaling factor that is included in the name of the image files. For instance, icons with a Retina scaling factor of 2 will include *@2x* in the name (for example, `myIcon@2x.png`).

Developers should not specify the path of the alternate icons (*@2x* or *@3x*) in the ***Action** dialog box* or the *XMLNodeRendererCustomizer API*. When using a Retina or HiDPI display, Oxygen XML Editor automatically searches the folder of the *normal* icon for a corresponding image file with a Retina scaling factor in the name. If the higher resolution icon file does not exist, the *normal* icon is scaled and used instead.

Retina/HiDPI Images in Author Mode on page 623

Java API - Extending Author Functionality through Java

Oxygen XML Editor **Author** mode has a built-in set of operations covering the insertion of text and XML fragments (see the *Author Default Operations*) and the execution of XPath expressions on the current document edited in **Author** mode. However, there are situations in which you need to extend this set. The following examples are just a few of the possible situations:

- You need to enter an element whose attributes will be edited by the user through a graphical user interface.
- The user must send selected element content (or the whole document) to a server for some kind of processing.
- Content authors need to extract pieces of information from a server and insert it directly into the edited XML document.
- You need to apply an XPath expression on the current document and process the nodes of the resulting node set.

To extend the Oxygen XML Editor **Author** mode functionality through Java, you will need the *Oxygen SDK* available *on the Oxygen XML Editor website*. It includes the source code of the **Author** mode operations in the predefined document types and the full documentation (in Javadoc format) of the public API available for **Author** mode custom actions.

The subsequent Java examples make use of AWT classes. If you are developing extensions for the Oxygen XML Editor XML Editor plugin for Eclipse, you will have to use their SWT counterparts.

Attention: Make sure the Java classes of your custom **Author** mode operations are compiled with the same Java version used by Oxygen XML Editor. Otherwise, the classes may not be loaded by the Java virtual machine. For example, if you run Oxygen XML Editor with a Java 1.6 virtual machine but the Java classes of your custom **Author** mode operations are compiled with a Java 1.7 virtual machine then the custom operations cannot be loaded and used by the Java 1.6 virtual machine.

Related Information:

Example 1- Simple Use of a Dialog Box from an Author Mode Operation

In this example, we start adding functionality for inserting images in a custom *framework*. The images are represented by the `image` element. The location of the image file is represented by the value of the `href` attribute. In the Java implementation, a dialog box will be displayed with a text field, in which the user can enter a full URL or browse for a local file.

1. Setup a sample project following *this set of instructions*. The *framework* project is **oxygen-sample-framework**.
2. Modify the *simple.documentation.framework.InsertImageOperation* class that implements the *ro.sync.ecss.extensions.api.AuthorOperation* interface. This interface defines three methods: *doOperation*, *getArguments* and *getDescription*

   A short description of these methods follows:

   - The *doOperation* method is invoked when the action is performed either by pressing the toolbar button, by selecting the menu item or by pressing the shortcut key. The arguments taken by this methods can be one of the following combinations:
     - an object of type *ro.sync.ecss.extensions.api.AuthorAccess* and a map
     - argument names and values
   - The *getArguments* method is used by Oxygen XML Editor when the action is configured. It returns the list of arguments (name and type) that are accepted by the operation.
   - The *getDescription* method is used by Oxygen XML Editor when the operation is configured. It returns a description of the operation.

   Example:

   Here is the implementation of these three methods:

```
/**
 * Performs the operation.
 */
public void doOperation(
           AuthorAccess authorAccess,
           ArgumentsMap arguments)
    throws IllegalArgumentException,
              AuthorOperationException {

JFrame oxygenFrame = (JFrame) authorAccess.getWorkspaceAccess().getParentFrame()
;
    String href = displayURLDialog(oxygenFrame);
     if (href.length() != 0) {
       // Creates the image XML fragment.
       String imageFragment =
         "<image xmlns='http://www.oxygenxml.com/sample/documentation' href='"
          + href + "'/>";

       // Inserts this fragment at the cursor position.
       int caretPosition = authorAccess.getEditorAccess().getCaretOffset();
       authorAccess.getDocumentController().insertXMLFragment
(imageFragment, caretPosition);
 }
}

/**
 * Has no arguments.
 *
 * @return null.
 */
public ArgumentDescriptor[] getArguments() {
 return null;
}

/**
 * @return A description of the operation.
```

```
 */
public String getDescription() {
 return "Inserts an image element. Asks the user for a URL reference.";
}
```

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Important:

Make sure you always specify the namespace of the inserted fragments.

```
<image xmlns='http://www.oxygenxml.com/sample/documentation'
  href='path/to/image.png'/>
```

3. Package the compiled class into a *JAR* file. An example of an Ant script that packages the `classes` folder content into a *JAR* archive named `sdf.jar` is listed below:

```
<?xml version="1.0" encoding="UTF-8"?>
<project name="project" default="dist">
    <target name="dist">
   <jar destfile="sdf.jar" basedir="classes">
    <fileset dir="classes">
     <include name="**/*"/>
     </fileset>
   </jar>
    </target>
</project>
```

4. Copy the `sdf.jar` file into your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).
5. Add the `sdf.jar` to the class path. To do this, *open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Document Type Association**, select **SDF**, and press the **Edit** button.
6. Select the **Classpath** tab in the lower part of the ***Document Type** configuration dialog box* and press the **Add** button . In the displayed dialog box, enter the location of the *JAR* file, relative to the Oxygen XML Editor `frameworks` folder.
7. We now create the action that will use the defined operation. Go to the **Actions** subtab.
   Copy the icon files for the menu item and for the toolbar in your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).
8. Define the action's properties:
   - Set **ID** to **insert_image**.
   - Set **Name** to **Insert image**.
   - Set **Menu access key** to letter **i**.
   - Set **Toolbar action** to **${framework}/toolbarImage.png**.
   - Set **Menu icon** to **${framework}/menuImage.png**.
   - Set **Shortcut key** to **Ctrl (Meta on Mac OS)+Shift+i**.
9. Next, we set up the operation. You want to add images only if the current element is a `section`, `book` or `article`.
   - Set the value of **XPath expression** to

     ```
     local-name()='section' or local-name()='book'
      or local-name()='article'
     ```

   - Set the **Invoke operation** field to *simple.documentation.framework.InsertImageOperation*.

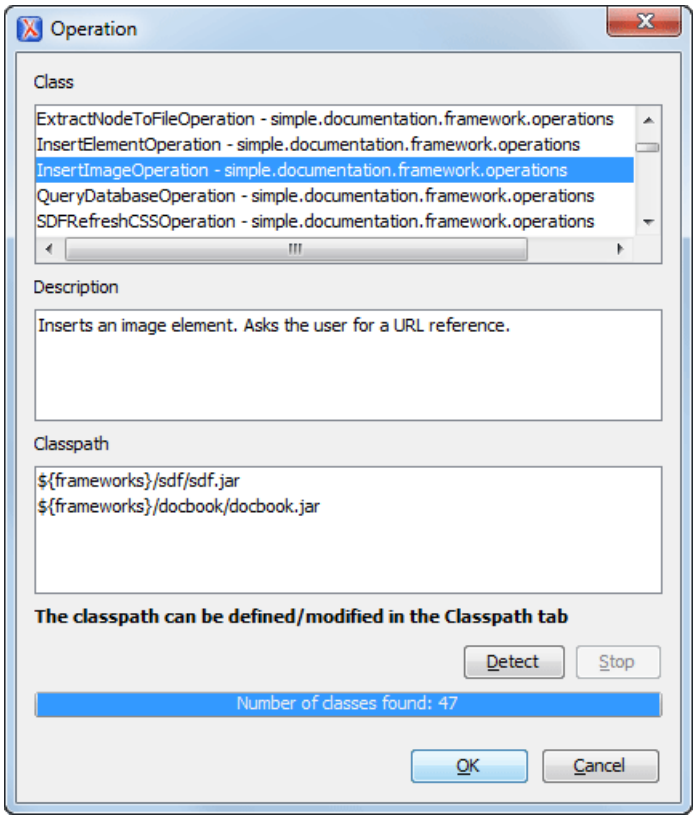

Figure 713: Selecting the Operation

10. Add the action to the toolbar, using the **Toolbar** panel.

To test the action, you can open the *sdf_sample.xml* sample, then place the cursor inside a `section` between two para elements (for instance). Press the button associated with the action from the toolbar. In the dialog box, select an image URL and press **OK**. The image is inserted into the document.

Example 2- Operations with Arguments. Report from Database Operation

In this example you will create an operation that connects to a relational database and executes an SQL statement. The result should be inserted in the edited XML document as a `table`. To make the operation fully configurable, it will have arguments for the *database connection string*, the *user name*, the *password* and the *SQL expression*.

1. Setup a sample project following *this set of instructions*. The *framework* project is **oxygen-sample-framework**.
2. Create the class *simple.documentation.framework.QueryDatabaseOperation*. This class must implements the *ro.sync.ecss.extensions.api.AuthorOperation* interface.

```
import ro.sync.ecss.extensions.api.ArgumentDescriptor;
import ro.sync.ecss.extensions.api.ArgumentsMap;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorOperation;
import ro.sync.ecss.extensions.api.AuthorOperationException;

public class QueryDatabaseOperation implements AuthorOperation{
```

3. Now define the operation's arguments. For each of them you will use a `String` constant representing the argument name:

```
private static final String ARG_JDBC_DRIVER ="jdbc_driver";
private static final String ARG_USER ="user";
private static final String ARG_PASSWORD ="password";
private static final String ARG_SQL ="sql";
private static final String ARG_CONNECTION ="connection";
```

4. You must describe each of the argument name and type. To do this, implement the *getArguments* method that will return an array of argument descriptors:

```
public ArgumentDescriptor[] getArguments() {
  ArgumentDescriptor args[] = new ArgumentDescriptor[] {
    new ArgumentDescriptor(
      ARG_JDBC_DRIVER,
      ArgumentDescriptor.TYPE_STRING,
      "The name of the Java class that is the JDBC driver."),
    new ArgumentDescriptor(
      ARG_CONNECTION,
      ArgumentDescriptor.TYPE_STRING,
      "The database URL connection string."),
    new ArgumentDescriptor(
      ARG_USER,
      ArgumentDescriptor.TYPE_STRING,
      "The name of the database user."),
    new ArgumentDescriptor(
      ARG_PASSWORD,
      ArgumentDescriptor.TYPE_STRING,
      "The database password."),
    new ArgumentDescriptor(
      ARG_SQL,
      ArgumentDescriptor.TYPE_STRING,
      "The SQL statement to be executed.")
  };
  return args;
 }
```

   These names, types and descriptions will be listed in the **Arguments** table when the operation is configured.

5. When the operation is invoked, the implementation of the *doOperation* method extracts the arguments, forwards them to the method that connects to the database and generates the XML fragment. The XML fragment is then inserted at the cursor position.

```
public void doOperation(AuthorAccess authorAccess, ArgumentsMap map)
   throws IllegalArgumentException, AuthorOperationException {

  // Collects the arguments.
  String jdbcDriver =
   (String)map.getArgumentValue(ARG_JDBC_DRIVER);
  String connection =
   (String)map.getArgumentValue(ARG_CONNECTION);
  String user =
   (String)map.getArgumentValue(ARG_USER);
  String password =
   (String)map.getArgumentValue(ARG_PASSWORD);
  String sql =
   (String)map.getArgumentValue(ARG_SQL);

  int caretPosition = authorAccess.getCaretOffset();
  try {
   authorAccess.getDocumentController().insertXMLFragment(
     getFragment(jdbcDriver, connection, user, password, sql),
     caretPosition);
  } catch (SQLException e) {
   throw new AuthorOperationException(
     "The operation failed due to the following database error: "
     + e.getMessage(), e);
  } catch (ClassNotFoundException e) {
   throw new AuthorOperationException(
     "The JDBC database driver was not found. Tried to load ' "
     + jdbcDriver + "'", e);
  }
 }
```

6. The *getFragment* method loads the JDBC driver, connects to the database and extracts the data. The result is a `table` element from the `http://www.oxygenxml.com/sample/documentation` namespace. The `header` element contains the names of the SQL columns. All the text from the XML fragment is escaped. This means that the '<' and '&' characters are replaced with the '<' and '&' character entities to ensure the fragment is well-formed.

```
private String getFragment(
  String jdbcDriver,
  String connectionURL,
  String user,
  String password,
  String sql) throws
   SQLException,
   ClassNotFoundException {

      Properties pr = new Properties();
      pr.put("characterEncoding", "UTF8");
      pr.put("useUnicode", "TRUE");
      pr.put("user", user);
      pr.put("password", password);
```

```
        // Loads the database driver.
        Class.forName(jdbcDriver);
        // Opens the connection
        Connection connection =
           DriverManager.getConnection(connectionURL, pr);
        java.sql.Statement statement =
           connection.createStatement();
        ResultSet resultSet =
           statement.executeQuery(sql);

        StringBuffer fragmentBuffer = new StringBuffer();
        fragmentBuffer.append(
          "<table xmlns=" +
          "'http://www.oxygenxml.com/sample/documentation'>");

        //
        // Creates the table header.
        //
        fragmentBuffer.append("<header>");
        ResultSetMetaData metaData = resultSet.getMetaData();
        int columnCount = metaData.getColumnCount();
        for (int i = 1; i <= columnCount; i++) {
            fragmentBuffer.append("<td>");
            fragmentBuffer.append(
              xmlEscape(metaData.getColumnName(i)));
            fragmentBuffer.append("</td>");
        }
        fragmentBuffer.append("</header>");

        //
        // Creates the table content.
        //
        while (resultSet.next()) {
            fragmentBuffer.append("<tr>");
            for (int i = 1; i <= columnCount; i++) {
                fragmentBuffer.append("<td>");
                fragmentBuffer.append(
                  xmlEscape(resultSet.getObject(i)));
                fragmentBuffer.append("</td>");
            }
            fragmentBuffer.append("</tr>");
        }

        fragmentBuffer.append("</table>");

        // Cleanup
        resultSet.close();
        statement.close();
        connection.close();
        return fragmentBuffer.toString();
    }
```

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

7. Package the compiled class into a *JAR* file.
8. Copy the *JAR* file and the JDBC driver files into your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).
9. Add the *JARS* to the class path. To do this, open the ***Document Type Association*** *preferences page*, select **SDF** and press the **Edit** button. Select the **Classpath** tab in the lower part of the ***Document Type*** *configuration dialog box* and press the **Add** button . In the displayed dialog box, enter the location of the *JAR* file, relative to the Oxygen XML Editor `frameworks` folder.
10. Go to the **Actions** subtab. The action properties are:
    - Set **ID** to **clients_report**.
    - Set **Name** to **Clients Report**.
    - Set **Menu access key** to letter **r**.
    - Set **Description** to **Connects to the database and collects the list of clients**.
    - Set **Toolbar icon** to **${framework}/TableDB20.png** (image `TableDB20.png` is already stored in the `frameworks / sdf` folder).
    - Leave empty the **Menu icon**.
    - Set **shortcut key** to **Ctrl + Shift + C (Command + Shift + C on OS X)**.
11. The action will work only if the current element is a **section**. Set up the operation as follows:
    - Set **XPath expression** to:

      ```
      local-name()='section'
      ```

- Use the Java operation defined earlier to set the **Invoke operation** field. Press the **Choose** button, then select *simple.documentation.framework.QueryDatabaseOperation*. Once selected, the list of arguments is displayed. In the figure below the first argument, *jdbc_driver*, represents the class name of the MySQL JDBC driver. The connection string has the URL syntax : *jdbc://<database_host>:<database_port>/<database_name>*.

  The SQL expression used in the example follows, but it can be any valid SELECT expression that can be applied to the database:

```
SELECT userID, email FROM users
```

12. Add the action to the toolbar, using the **Toolbar** panel.

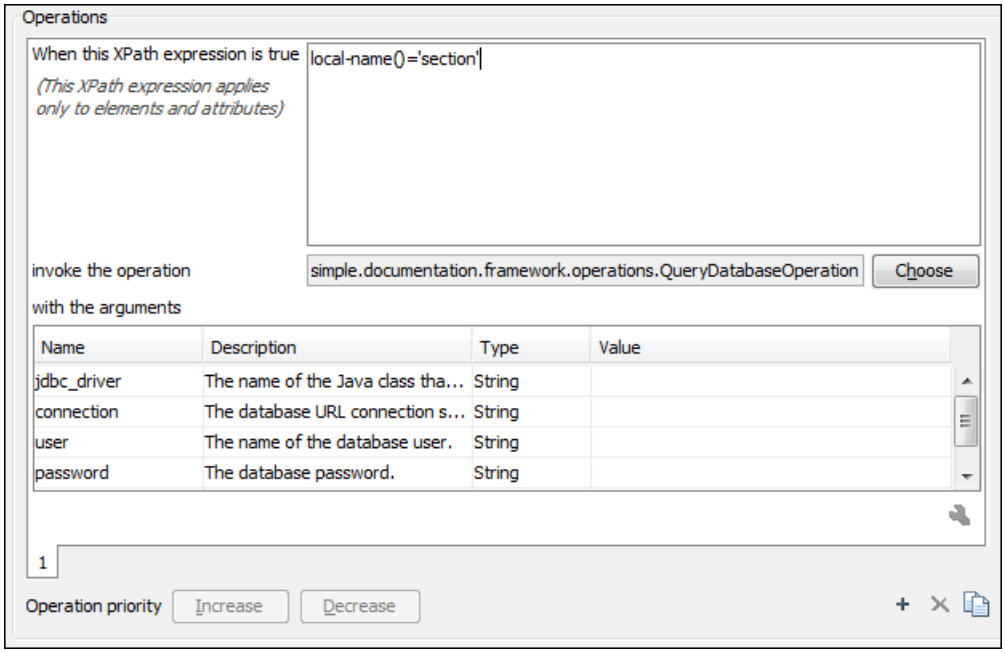

Figure 714: Java Operation Arguments Setup

To test the action, you can open the *sdf_sample.xml* sample and place the cursor inside a `section` between two para elements (for instance). Press the **Create Report** button from the toolbar. You can see below the toolbar with the action button and sample table inserted by the **Clients Report** action.

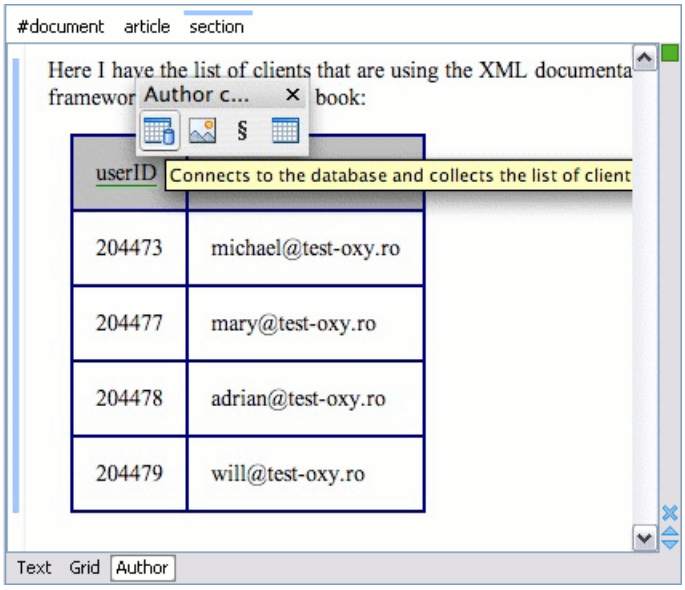

Figure 715: Table Content Extracted from the Database

Localizing Frameworks

Oxygen XML Editor supports *framework* localization (translating *framework* actions, buttons, and menu entries to various languages). This lets you develop and distribute a *framework* to users that speak other languages without changing the distributed *framework*. Changing the language used in Oxygen XML Editor in the Global preferences page is enough to set the right language for each *framework*.

To localize the content of a *framework*, create a `translation.xml` file that contains all the translation (key, value) mappings. The `translation.xml` has the following format:

```
<translation>
    <languageList>
        <language description="English" lang="en_US"/>
        <language description="German" lang="de_DE"/>
        <language description="French" lang="fr_FR"/>
    </languageList>
    <key value="list">
        <comment>List menu item name.</comment>
        <val lang="en_US">List</val>
        <val lang="de_DE">Liste</val>
        <val lang="fr_FR">Liste</val>
    </key>
.....................
</translation>
```

Oxygen XML Editor matches the GUI language with the language set in the `translation.xml` file. If this language is not found, the first available language declared in the `languagelist` tag for the corresponding *framework* is used.

Add the directory where this file is located to the **Classpath** list corresponding to the edited document type.

After you create this file, you can use the keys defined in it to customize the name and description of the following:

- Actions
- Menu entries
- Contextual menus
- Toolbars
- Static CSS content

For example, if you want to localize the bold action, *open the **Preferences** dialog box **(Options** > **Preferences)*** and go to **Document Type Association**. Use the **New** or **Edit** button to open the ***Document type** configuration dialog box*, go to **Author** > **Actions**, and rename the bold action to `${i18n(translation_key)}`. Actions with a name format other than `${i18n(translation_key)}` are not localized. *Translation_key* corresponds to the key from the translation.xml file.

Now open the `translation.xml` file and edit the translation entry if it exists or create one if it does not exist. This example presents an entry in the translation.xml file:

```
<key value="translation_key">
        <comment>Bold action name.</comment>
        <val lang="en_US">Bold</val>
        <val lang="de_DE">Bold</val>
        <val lang="fr_FR">Bold</val>
    </key>
```

To use a description from the `translation.xml` file in the Java code used by your custom *framework*, use the new *ro.sync.ecss.extensions.api.AuthorAccess.getAuthorResourceBundle()* API method to request the associated value for a certain key. This allows all the dialog boxes that you present from your custom operations to have labels translated in multiple languages.

You can also reference a key directly in the CSS content:

```
title:before{
    content:"${i18n(title.key)} : ";
}
```

Note: You can enter any language you want in the `languagelist` tag and any number of keys.

The `translation.xml` file for the DocBook *framework* is located here:*[OXYGEN_INSTALL_DIR]*`/frameworks/docbook/i18n/translation.xml`. In the **Classpath** list corresponding to the DocBook document type the following entry was added: `${framework}/i18n/`.

To see how the DocBook actions are defined to use these keys for their name and description, *open the **Preferences** dialog box **(Options > Preferences)*** and go to **Document Type Association** > **Author** > **Actions**. If you look in the Java class *ro.sync.ecss.extensions.docbook.table.SADocbookTableCustomizerDialog* available in the *oxygen-sample-framework* module of the *Oxygen SDK* Maven archetype, you can see how the new *ro.sync.ecss.extensions.api.AuthorResourceBundle* API is used to retrieve localized descriptions for various keys.

Packing and Deploying Plugins or Frameworks as Add-ons

Packing a Plugin or Framework as an Add-on

This procedure is suitable for developers who want a better control over the *add-on* package or those who want to automate some of the steps:

1. Pack the *plugin* or *framework* as a `ZIP` file or a *Java Archive*. Note that you should pack the entire root directory not just its contents.
2. Digitally sign the package. Note that you can perform this step only if you have created a *Java Archive* at the previous step. You will need a certificate signed by a trusted authority. To sign the *JAR* you can either use the *jarsigner* command line tool inside Oracle's Java Development Kit. (`[JDK_DIR]/bin/jarsigner.exe`) or, if you are working with *Apache Ant*, you can use the *signjar* task (a front for the *jarsigner* command line tool).

   Note: The benefit of having a signed add-on is that you can verify the integrity of the add-on issuer. If you do not have such a certificate you can generate one yourself using the *keytool* command line tool. This approach is mostly recommended for tests since anyone can create a self signed certificate.
3. Create a descriptor file. You can use a template that Oxygen XML Editor provides. To use this template, go to **File** > **New** and select the **Oxygen add-ons update site** template. Once deployed, this descriptor file is referenced as *update site*.

Alternatively, you can use the **Add-ons Packager** plugin by following this procedure:

1. Install the **Add-ons Packager** plugin from *https://www.oxygenxml.com/InstData/Addons/optional/updateSite.xml* as described in the *Installing Add-ons procedure*.
2. Restart Oxygen XML Editor. If the add-on is correctly installed, the **Add-ons packager** toolbar action is available.
3. Invoke the **Add-ons packager** toolbar action and input the required information in the displayed dialog box.
4. Press **OK** to complete the packaging process.

Deploying an Add-on

To deploy an add-on, copy the `ZIP` or *Java Archive* file and the descriptor file to an HTTP server. The URL to this location serves as the *Update Site URL*.

Configuring New File Templates

A customized *framework* (document type) can point to a directory, usually named `templates`, that contains the file templates. All files found here are considered templates for the respective document type. The template name is taken from the file name, and the template type is detected from the file extension.

To customize new file templates for a *framework*, follow these steps:

1. Go to your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`) and create a directory named `templates`.
   The directory tree of the custom documentation *framework* should be something like this:

```
[OXYGEN_INSTALL_DIR]
    frameworks
        [CUSTOM_FRAMEWORK_DIR]
            schema
            css
            templates
```

2. In the `templates` directory, create two files. A file for the *book* template and another one for the *article* template.

   An example for the `Book.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<book xmlns="http://www.oxygenxml.com/sample/documentation"
xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:abs="http://www.oxygenxml.com/sample/documentation/abstracts">
    <title>Book Template Title</title>
    <section>
        <title>Section Title</title>
        <abs:def/>
        <para>This content is copyrighted:</para>
        <table>
            <header>
                <td>Company</td>
                <td>Date</td>
            </header>
            <tr>
                <td/>
                <td/>
            </tr>
        </table>
    </section>
    </book>
```

   An example for the `Article.xml` file:

```
<?xml version="1.0" encoding="UTF-8"?>
<article
    xmlns="http://www.oxygenxml.com/sample/documentation"
    xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
    <title></title>
    <section>
        <title></title>
        <para></para>
        <para></para>
    </section>
</article>
```

   You can also use *editor variables* in the content of the template files and they will be expanded when the files are opened.

   Note: You should avoid using the `${cfd}`,`${cf}`,`${currentFileURL}`, and `${cfdu}` *editor variables* when you save your documents in a data base.
3. Open the ***Document Type*** *configuration dialog box* for your custom *framework* and click the **Templates** tab. In the **Templates directory** text field, introduce the `${frameworkDir}/templates` path. It is recommended that all the file references made from a *Document Type Association* to be relative to the **${frameworkDir}** directory. Binding to an absolute file (e. g.: `C:\some_dir\templates`) makes the association difficult to share between users.
4. To test the templates settings, go to **File** > **New** to display the **New** document dialog box. You should see the new templates in the folder for your custom *framework* (in the **Framework templates** section). The names of the two templates are prefixed with the name of the *framework*. Selecting one of them should create a new XML file with the content specified in the template file.

Configuring XML Catalogs

For cases where you need to reference the location of a schema file from a remote web location and an Internet connection may not be available, an *XML Catalog* may be used to map the web location to a local file system entry. The following procedure presents an example of using an *XML catalog* in a custom *framework* by modifying an XML Schema file.

1. Create a catalog file that will help the parser locate the schema for validating the XML document. The file must map the location of the schema to a local version of the schema.

   Example:

Create a new XML file called `catalog.xml` and save it in your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`). The content of the file should look like this:

```
<?xml version="1.0"?>
<catalog xmlns="urn:oasis:names:tc:entity:xmlns:xml:catalog">
    <uri name="http://www.oxygenxml.com/SDF/abs.xsd"
            uri="schema/abs.xsd"/>
    <uri name="http://www.oxygenxml.com/SDF/abs.xsd"
                uri="schema/abs.xsd"/>
</catalog>
```

2. Add catalog files to your custom *framework* using the ***Catalogs*** *tab* from the ***Document Type*** *configuration dialog box*.

To test the catalog settings, restart Oxygen XML Editor and try to validate a new sample document for your custom *framework*. There should be no errors.

Example:

The schema that validates the document refers the other file `abs.xsd` through an import element:

```
<xs:import namespace=
 "http://www.oxygenxml.com/sample/documentation/abstracts"
 schemaLocation="http://www.oxygenxml.com/SDF/abs.xsd"/>
```

The `schemaLocation` attribute references the `abs.xsd` file:

```
xsi:schemaLocation="http://www.oxygenxml.com/sample/documentation/abstracts"
    http://www.oxygenxml.com/SDF/abs.xsd"/>
```

The catalog mapping is:

```
http://www.oxygenxml.com/SDF/abs.xsd -> schema/abs.xsd
```

This means that all the references to http://www.oxygenxml.com/SDF/abs.xsd must be resolved to the `abs.xsd` file located in the `schema` directory (note that the `schema` directory needs to be in the same folder as the *XML Catalog*). The URI element is used by URI resolvers (for example, to resolve a URI reference used in an XSLT stylesheet).

Configuring Transformation Scenarios for a Framework

When distributing a *framework* to users, it is a good idea to have the transformation scenarios already configured. This helps the content authors publish their work in various formats. By being contained in the *framework* configuration, the scenarios can be distributed along with the actions, menus, toolbars, and catalogs.

These are the steps that allow you to create a transformation scenario for your *framework*.

1. Create an `xsl` folder inside your custom *framework* directory (*[OXYGEN_INSTALL_DIR]*`\frameworks\[CUSTOM_FRAMEWORK_DIR]`).

   The folder structure for the documentation *framework* should be:

   ```
   oxygen
     frameworks
        [CUSTOM_FRAMEWORK_DIR]
          schema
          css
          templates
          xsl
   ```

2. Create the `sdf.xsl` file in the `xsl` folder. The complete content of the `sdf.xsl` file is found in the *Example Files Listings*.
3. *Open the* ***Preferences*** *dialog box* ***(Options > Preferences)*** and go to **Document Type Associations**. Select the particular *framework*, click the **Edit** button to open ***Document Type*** *Configuration dialog box*, and choose the **Transformation** tab. Click the **New** button and choose the appropriate type of transformation (for example, **XML transformation with XSLT**).

   In the **New scenario** dialog box, fill in the following fields:

   - Fill in the **Name** field with the name of your transformation scenario.

- Set the **XSL URL** field to path of your custom stylesheet (for example, `${framework}/xsl/mycustom.xsl`).

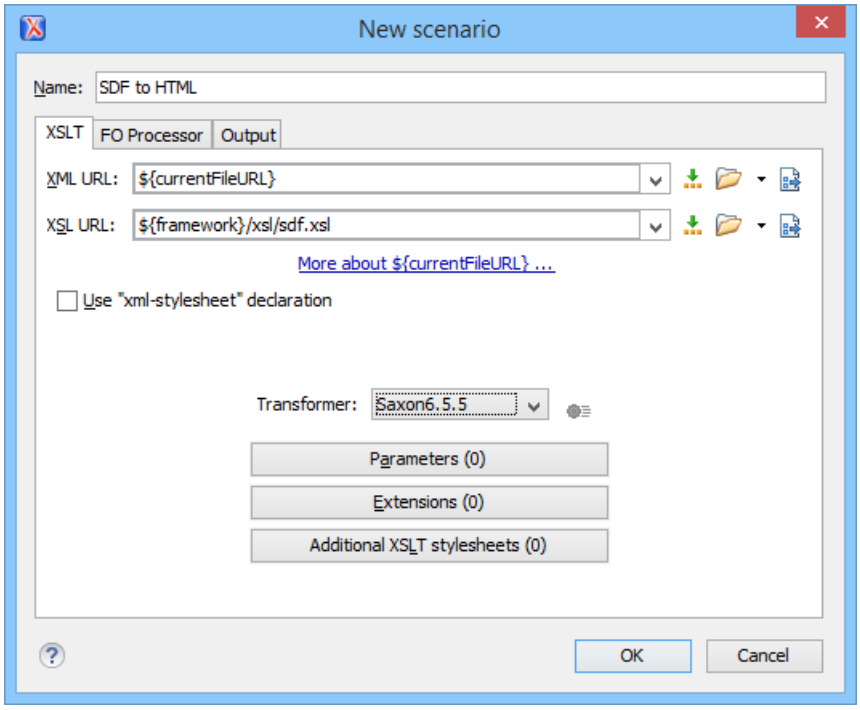

Figure 716: Configuring a New XSLT Transformation Scenario

4. Change to the **Output** tab. Configure the fields as follows:
   - Set the **Save as** field to `${cfd}/${cfn}.html`. This means the transformation output file will have the name of the XML file and the *html* extension and will be stored in the same folder.
   - Select the **Open in Browser/System Application** option.

     Note: To set the browser or system application that will be used, *open the **Preferences** dialog box (**Options** > **Preferences**)*, go to **Global**, and set it in the **Default Internet browser** field. This will take precedence over the default system application settings.
   - Select the **Saved file** option.
5. Click the **OK** button to save the new scenario.

Now the scenario is listed in the **Transformation** tab:

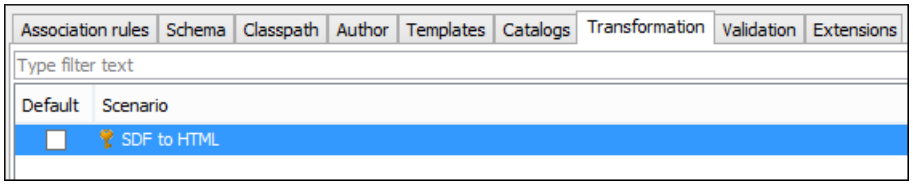

Figure 717: Transformation Tab

To test the transformation scenario that you just created, open the **SDF** XML sample from the *Example Files Listings*. Click the **Apply Transformation Scenario(s)** button to display the **Transform with** dialog box. The scenario list contains the scenario you defined earlier . Select the *SDF to HTML* scenario that you just defined and click the **Apply associated** button. The HTML file is saved in the same folder as the XML file and displayed in the browser.

Configuring Validation Scenarios for a Framework

You can distribute a *framework* with a series of already configured validation scenarios. Also, this provides enhanced validation support that allows you to use multiple grammars to check the document. For example,

you can use Schematron rules to impose guidelines that are otherwise impossible to enforce using conventional validation.

Note: If a *master file* is associated with the current file, the validation scenarios defined in the *master file*, along with any Schematron schema defined in the default scenarios for that particular *framework*, are used for the validation. These take precedence over other types of validation units defined in the default scenarios for the particular *framework*. For more information on *master files*, see *Master Files Support* on page 466 or *Working with Modular XML Files in the Master Files Context* on page 692.

To associate a validation scenario with a specific *framework*, follow these steps:

1. *Open the **Preferences** dialog box **(Options > Preferences)*** and go to **Document Type Association**.
2. Select the document type and click the **Edit** button to open the ***Document Type Configuration** dialog box*, then choose the **Validation** tab. This tab displays a list of document types in which you can define validation scenarios. To set one or more of the validation scenarios listed in this tab to be used as the default validation scenario (when another one is not specified in the validation process) for a specific document type, check the **Default** box for that specific document type.
3. To add a new scenario, press the **New** button.
   The **New scenarios** dialog box is displayed. It lists all the validation units for the scenario.

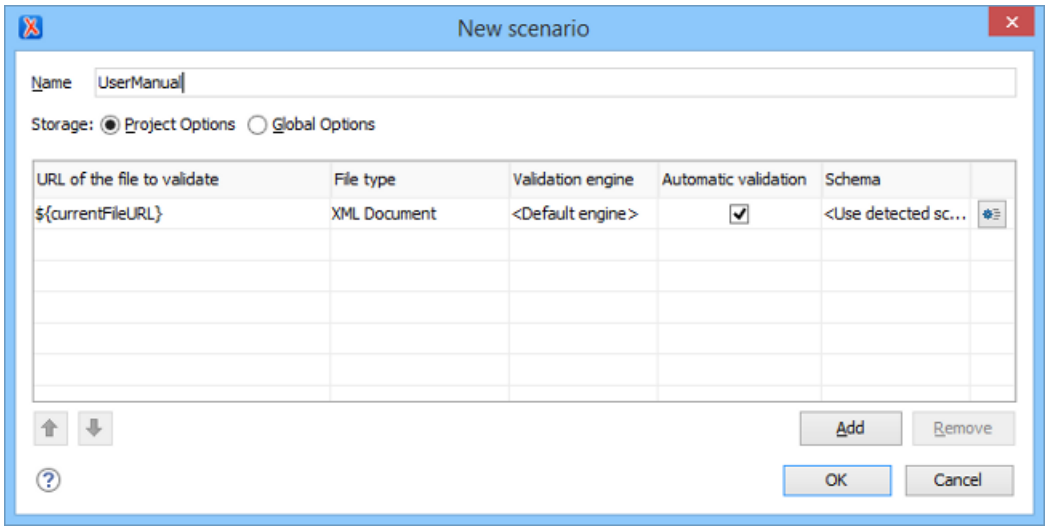

Figure 718: Create New Validation Scenario

This scenario configuration dialog box allows you to configure the following information and options:

Name

The name of the validation scenario.

Storage

You can choose between storing the scenario in the ***Project Options*** or ***Global Options***.

URL of the file to validate

The URL of the main module that includes the current module. It is also the entry module of the validation process when the current one is validated. To edit the URL, double-click its cell and specify the URL of the main module by doing one of the following:

- Enter the URL in the text field or select it from the drop-down list.
- Use the **Browse** drop-down button to browse for a local, remote, or archived file.
- Use the **Insert Editor Variable** button to insert an *editor variable* or a *custom editor variable*.

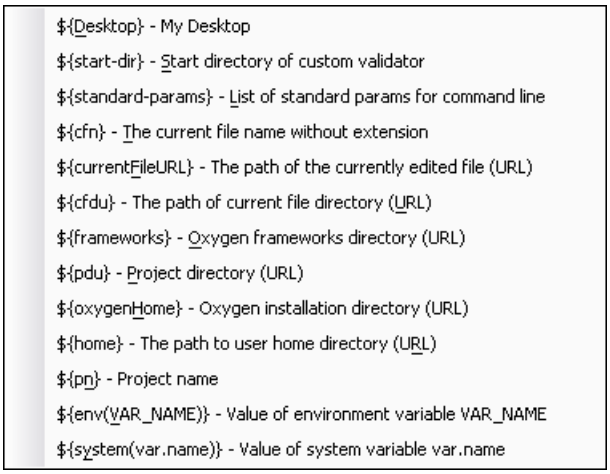

Figure 719: Insert an Editor Variable

File type

The type of the document that is validated in the current validation unit. Oxygen XML Editor automatically selects the file type depending on the value of the **URL of the file to validate** field.

Validation engine

You can select one of the engines available in Oxygen XML Editor for validation of the particular document type.

Default engine means that the default engine is used to run the validation for the current document type, as specified in the preferences page for that type of document (for example, *XSLT preferences page*, *XQuery preferences page*, *XML Schema preferences page*).

The **DITA Validation** engine performs DITA-specific checks in the context of the specifications (it is similar to the checks done with the **DITA Maps Manager** ***Validate and Check for Completeness*** *action*, but for a local file rather than an entire *DITA map*).

The **Table Layout Validation** engine looks for table layout problems (for more information, see *Report table layout problems* on page).

Automatic validation

If this option is selected, the validation operation defined by this row is also applied by *the automatic validation feature*. If the **Automatic validation** feature is disabled in the *Document Checking preferences page*, then this option is ignored, as the preference setting has a higher priority.

Schema

This option becomes active when you set the **File type** to **XML Document** and allows you to specify the schema used for the validation unit.

Specify Schema

Opens the **Specify Schema** dialog box that allows you to set a schema to be used for validating XML documents.

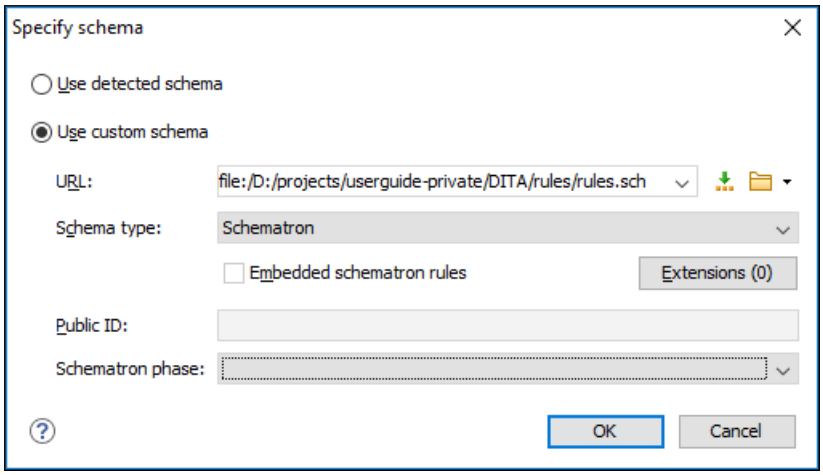

Figure 720: Specify Schema Dialog Box

The **Specify Schema** dialog box contains the following options:

Use detected schema

Uses the *schema detected for the particular document*.

Use custom schema

Allows you to specify the schema using the following options:

- **URL** - Allows you to specify or select a URL for the schema. It also keeps a history of the last used schemas. The URL must point to the schema file that can be loaded from the local disk or from a remote server through HTTP(S), FTP(S) or a *custom protocol*. You can specify the URL by using the text field, the history drop-down, the ***Insert Editor Variables*** button, or the browsing tools in the **Browse** drop-down list.
- **Schema type** - Select a possible schema type from this combo box that is populated based on the extension of the schema file that was entered in the **URL** field. The possible schema types are: XML Schema, DTD, Relax NG, Relax NG Compact, Schematron, or NVDL.
- **Embedded schematron rules** - If you have selected XML Schema or Relax NG schemas with embedded Schematron rules and you want to use those embedded rules, select this option.
- **Extensions**- Opens a dialog box that allows you to specify *Java extension JARs* to be used during the validation.
- **Public ID** - Allows you to specify a public ID if you have selected a DTD.
- **Schematron phase** - If you select a Schematron schema, this drop-down list allows you to select a Schematron phase that you want to use for validation. The listed phases are defined in the Schematron document.

Move Up

Moves the selected scenario up one spot in the list.

Move Down

Moves the selected scenario down one spot in the list.

Add

Adds a new validation unit to the list.

Remove

Removes an existing validation unit from the list.

4. Configure any of the existing validation units according to the information above, and you can use the buttons at the bottom of the table to add, remove, or move validation units. Note that if you add a Schematron validation unit, you can also select the **validation phase**.
5. Press **Ok**.

The newly created validation scenario is now included in the list of scenarios in the ***Validation** tab*. You can use the **Default** checkbox to specify that the new scenario be used as the default validation scenario when another specific scenario is not specified in the validation process.

Customizing Smart Paste Support

The *Smart Paste feature* preserves certain style and structure information when copying content from some of the most common applications and pasting into *frameworks (document types) that support Smart Paste* in Oxygen XML Editor. For other document types, the default behavior of the paste operation is to keep only the text content without the styling.

The style of the pasted content can be customized by editing an XSLT stylesheet for a particular document type (*framework*). The XSLT stylesheet must accept an XHTML flavor of the copied content as input, and transform it to the equivalent XML markup that is appropriate for the target document type of the paste operation.

How to Customize the Smart Paste Mapping

To customize the mapping between the markup of the copied content and the markup of the pasted content for a particular document type, follow these steps:

1. Make sure the particular *framework* contains a folder named `resources` in the following path structure:

   [OXYGEN_INSTALL_DIR]`/frameworks/[Document Type]/resources`
2. Create an XSLT file named `xhtml2content.xsl` and save it in the `resources` folder for the particular *framework*.

   For example: *[OXYGEN_INSTALL_DIR]*`/frameworks/dita/resources/xhtml2content.xsl`
3. Add your customized styling in the XSLT file.
4. You can test modifications done in the stylesheet by pasting content without having to restart Oxygen XML Editor.

Result: When you paste content from external applications (such as a web browser or and Office document) to a document that is opened in **Author** mode, and that matches the particular *framework*, the styling from the `xhtml2content.xsl` stylesheet will be applied on the clipboard contents.

Customized Smart Paste Stylesheet Sample:

```
<xsl:stylesheet version="1.0"
  xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
  xmlns:xhtml="http://www.w3.org/1999/xhtml"
  xmlns="urn:hl7-org:v3"
  exclude-result-prefixes="xsl xhtml">

  <xsl:output method="xml" indent="no" omit-xml-declaration="yes"/>

  <xsl:template match="xhtml:b | xhtml:strong">
    <content styleCode="bold" >
      <xsl:apply-templates select="@* | node()"/>
    </content>
  </xsl:template>

  <xsl:template match="*">
    <xsl:apply-templates select="@* | node()"/>
  </xsl:template>

  <xsl:template match="@* | node()">
    <xsl:copy>
      <xsl:apply-templates select="@* | node()"/>
    </xsl:copy>
  </xsl:template>

</xsl:stylesheet>
```

Oxygen XML Blog: How Special Paste Works in Oxygen

Configuring Extensions

You can add *extensions* to your custom *framework* (document type) by using the **Extensions** tab from the ***Document Type** configuration dialog box*.

Note: It is possible for a *plugin* to share the same classes with a *framework*. For further details, go to *How to Share the Classloader Between a Framework and a Plugin*.

Configuring an Extensions Bundle

All *extensions* that are provided by Oxygen XML Editor are includes in a single bundle.

Note: The individual extensions can still be set (*open the **Preferences** dialog box **(Options > Preferences)***, go to **Document Type Association**, double-click a document type, and go to the extension tab), and if present, they take precedence over the single provider. However, this practice is discouraged and the single provider should be used instead.

The extensions bundle is represented by the *ro.sync.ecss.extensions.api.ExtensionsBundle* class. The provided implementation of the `ExtensionsBundle` is instantiated when the *Document Type Association* rules defined for the custom *framework* matches a document opened in the editor. Therefore, references to objects that need to be persistent throughout the application running session must not be kept in the bundle because the next detection event can result in creating another *ExtensionsBundle* instance.

To configure an extensions bundle, follow this procedure:

1. Create a new Java project in your IDE. Create a `lib` folder in the Java project folder and copy in it the `oxygen.jar` file from the *`[OXYGEN_INSTALL_DIR]`*`/lib` folder.
2. Create the class (for example, *simple.documentation.framework.SDFExtensionsBundle*) to extend the abstract class *ro.sync.ecss.extensions.api.ExtensionsBundle*.

   For example:

   ```
   public class SDFExtensionsBundle extends ExtensionsBundle {
   ```

3. A `Document Type ID` and a short description should be defined first by implementing the methods *getDocumentTypeID* and *getDescription*. The `Document Type ID` is used to uniquely identify the current *framework*. Such an ID must be provided especially if options related to the *framework* need to be persistently stored and retrieved between sessions.

   For example:

   ```
   public String getDocumentTypeID() {
        return "Simple.Document.Framework.document.type";
   }

   public String getDescription() {
        return "A custom extensions bundle used for the Simple Document" +
                     "Framework document type";
   }
   ```

4. To be notified about the activation of the custom *Author Extension* in relation with an opened document, *ro.sync.ecss.extensions.api.AuthorExtensionStateListener* should be implemented. The **activation** and **deactivation** events received by this listener should be used to perform custom initializations and to register or remove listeners such as *ro.sync.ecss.extensions.api.AuthorListener*, *ro.sync.ecss.extensions.api.AuthorMouseListener*, or *ro.sync.ecss.extensions.api.AuthorCaretListener*. The custom *Author Extension* state listener should be provided by implementing the *createAuthorExtensionStateListener* method.

   For example:

   ```
   public AuthorExtensionStateListener createAuthorExtensionStateListener() {
        return new SDFAuthorExtensionStateListener();
   }
   ```

   The `AuthorExtensionStateListener` is instantiated and notified about the activation of the *framework* when the rules of the *Document Type Association* match a document opened in the **Author** editing mode. The listener is notified about the deactivation when another *framework* is activated for the same document, the user switches to another mode or the editor is closed. A complete description and implementation of *ro.sync.ecss.extensions.api.AuthorExtensionStateListener* can be found in *Implementing an Author Extension State Listener*.

   If *Schema Aware mode* is active in Oxygen XML Editor, all actions that can generate invalid content will be redirected toward the *ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandler*. The handler can resolve a specific case, let the default implementation take place, or reject the edit entirely by throwing an

ro.sync.ecss.extensions.api.InvalidEditException. The actions that are forwarded to this handler include typing, delete, or paste.

See *Implementing a Schema-Aware Editing Handler Adapter* on page 1432 for more details about this handler.

5. Customizations of the content completion proposals are permitted by creating a schema manager filter extension. The interface that declares the methods used for content completion proposals filtering is *ro.sync.contentcompletion.xml.SchemaManagerFilter*. The filter can be applied on elements, attributes, or on their values. The *createSchemaManagerFilter* method is responsible for creating the content completion filter. A new `SchemaManagerFilter` will be created each time a document matches the rules defined by the *Document Type Association* that contains the filter declaration.

   For example:

   ```
   public SchemaManagerFilter createSchemaManagerFilter() {
        return new SDFSchemaManagerFilter();
   }
   ```

   A detailed presentation of the schema manager filter can be found in the *Configuring a Content Completion Handler* section.

6. The **Author** mode supports link-based navigation between documents and document sections. Therefore, if the document contains elements defined as links to other elements (for example, links based on the `id` attributes), the extension should provide the means to find the referenced content. To do this, an implementation of the *ro.sync.ecss.extensions.api.link.ElementLocatorProvider* interface should be returned by the *createElementLocatorProvider* method. Each time an element pointed by a link needs to be located, the method is invoked.

   For example:

   ```
   public ElementLocatorProvider createElementLocatorProvider() {
        return new DefaultElementLocatorProvider();
   }
   ```

   For more information on how to implement an element locator provider, see the *Configuring a Link Target Element Finder* section.

7. The drag and drop functionality can be extended by implementing the *ro.sync.exml.editor.xmleditor.pageauthor.AuthorDnDListener* interface. Relevant methods from the listener are invoked when the mouse is dragged, moved over, or exits the **Author** editing mode, when the drop action changes, and when the drop occurs. Each method receives the `DropTargetEvent` containing information about the drag and drop operation. The drag and drop extensions are available in **Author** mode for both Oxygen XML Editor Eclipse plugin and standalone application. The **Text** mode corresponding listener is available only for Oxygen XML Editor Eclipse plugin. The methods corresponding to each implementation are: *createAuthorAWTDndListener*, *createTextSWTDndListener*, and *createAuthorSWTDndListener*.

   ```
   public AuthorDnDListener createAuthorAWTDndListener() {
        return new SDFAuthorDndListener();
   }
   ```

   For more details about the **Author** mode drag and drop listeners, see the *Configuring a custom Drag and Drop Listener* section.

8. Another extension that can be included in the bundle is the reference resolver. In our example, the references are represented by the **ref** element and the attribute indicating the referenced resource is **location**. To be able to obtain the content of the referenced resources you will have to implement a Java extension class that implements *ro.sync.ecss.extensions.api.AuthorReferenceResolver*. The method responsible for creating the custom references resolver is *createAuthorReferenceResolver*. The method is called each time a document opened in an **Author** editing mode matches the *Document Type Association* where the extensions bundle is defined. The instantiated references resolver object is kept and used until another extensions bundle corresponding to another document type is activated as result of the detection process.

   For example:

   ```
   public AuthorReferenceResolver createAuthorReferenceResolver() {
        return new ReferencesResolver();
   }
   ```

A more detailed description of the references resolver can be found in the *Configuring a References Resolver* section.

9. To be able to dynamically customize the default CSS styles for a certain *ro.sync.ecss.extensions.api.node.AuthorNode*, an implementation of *ro.sync.ecss.extensions.api.StylesFilter* can be provided. The extensions bundle method responsible for creating the `StylesFilter` is *createAuthorStylesFilter*. The method is called each time a document opened in an **Author** editing mode matches the *Document Type Association* where the extensions bundle is defined. The instantiated filter object is kept and used until another extensions bundle corresponding to another document type is activated as a result of the detection process.

   For example:

   ```
   public StylesFilter createAuthorStylesFilter() {
        return new SDFStylesFilter();
   }
   ```

   See the *Configuring CSS Styles Filter* section for more details about the styles filter extension.

10. To edit data in custom tabular format, implementations of the *ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider* and the *ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider* interfaces should be provided. The two methods from the `ExtensionsBundle` specifying these two extension points are *createAuthorTableCellSpanProvider* and *createAuthorTableColumnWidthProvider*.

    For example:

    ```
    public AuthorTableCellSpanProvider createAuthorTableCellSpanProvider() {
         return new TableCellSpanProvider();
    }

    public AuthorTableColumnWidthProvider
             createAuthorTableColumnWidthProvider() {
         return new TableColumnWidthProvider();
    }
    ```

    The two table information providers are not reused for different tables. The methods are called for each table in the document so new instances should be provided every time. Read more about the cell span and column width information providers in *Configuring a Table Cell Span Provider* and *Configuring a Table Column Width Provider* sections.

    If the functionality related to one of the previous extension point does not need to be modified, then the developed *ro.sync.ecss.extensions.api.ExtensionsBundle* should not override the corresponding method and leave the default base implementation to return **null**.

11. An XML vocabulary can contain links to various areas of a document. If the document contains elements defined as links, you can choose to present a more relevant text description for each link. To do this, an implementation of the *ro.sync.ecss.extensions.api.link.LinkTextResolver* interface should be returned by the *createLinkTextResolver* method. This implementation is used each time the *oxy_link-text() function* is encountered in the CSS styles associated with an element.

    For example:

    ```
    public LinkTextResolver createLinkTextResolver() {
      return new DitaLinkTextResolver();
    }
    ```

    Oxygen XML Editor offers built-in implementations for DITA and DocBook: *ro.sync.ecss.extensions.dita.link.DitaLinkTextResolver* and *ro.sync.ecss.extensions.docbook.link.DocbookLinkTextResolver* respectively.

12. Pack the compiled class into a *JAR* file.
13. Copy the *JAR* file into your custom *framework* directory (for example, `frameworks/sdf`).
14. Add the *JAR* file to the class path. To do this, *open the **Preferences** dialog box **(Options > Preferences)***, go to **Document Type Association**, select the document type (for example, *SDF*), press the **Edit** button, select the **Classpath** tab, and press the **Add** button . In the displayed dialog box, enter the location of the *JAR* file relative to the Oxygen XML Editor `frameworks` folder.

15. Register the Java class by going to the **Extensions** tab. Press the **Choose** button and select the name of the class (for example, *SDFExtensionsBundle*).

    Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Related Information:

Customizing Elements that Wrap Profiled Content

For each *framework* (document type), you can configure the phrase-type elements that wrap the profiled content by setting a custom *ro.sync.ecss.extensions.api.ProfilingConditionalTextProvider*. This configuration is set by default for DITA and DocBook *frameworks*.

Implementing a Schema-Aware Editing Handler Adapter

The *AuthorSchemaAwareEditingHandlerAdapter* extension point allows you to handle certain **Author** mode actions in various ways. For example, implementing the `AuthorSchemaAwareEditingHandlerAdapter` makes it possible to handle events such as typing, the keyboard delete event at a given offset (using Delete or Backspace keys), delete element tags, delete selection, join elements, or paste fragment. It also makes it possible to improve solutions that are proposed by the paste mechanism in Oxygen XML Editor when pasting content (through the use of *some specific methods*).

How to Implement an *AuthorSchemaAwareEditingHandlerAdapter*

For this handler to be called, the ***Schema Aware Editing*** *option* must be set to **On** or **Custom** in the ***Schema-Aware*** *preferences page*. The handler can either resolve a specific case, let the default implementation take place, or reject the edit entirely by throwing an `InvalidEditException`.

To implement your own *AuthorSchemaAwareEditingHandlerAdapter*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorSchemaAwareEditingHandlerAdapter* extension.
2. To instruct Oxygen XML Editor to use this newly created implementation, *configure an extensions bundle* and return the *AuthorSchemaAwareEditingHandlerAdapter* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorSchemaAwareEditingHandlerAdapter()* method.

Example

Typing events can be handled using the *handleTyping* method. For example, the `AuthorSchemaAwareEditingHandler` checks if the schema is not a learned one, was loaded successfully, and if the ***Smart paste and drag and drop*** *option* is selected. If these conditions are met, the event will be handled.

```
public class AuthorSchemaAwareEditingHandlerAdapter
              extends AuthorSchemaAwareEditingHandler {

/**
 * @see AuthorSchemaAwareEditingHandler#handleTyping
(int, char, ro.sync.ecss.extensions.api.AuthorAccess)
 */
public boolean handleTyping(int offset, char ch, AuthorAccess authorAccess)
throws InvalidEditException {
  boolean handleTyping = false;
  AuthorSchemaManager authorSchemaManager =
authorAccess.getDocumentController().getAuthorSchemaManager();
  if (!authorSchemaManager.isLearnSchema() &&
      !authorSchemaManager.hasLoadingErrors() &&
      authorSchemaManager.getAuthorSchemaAwareOptions().isEnableSmartTyping()) {
    try {
      AuthorDocumentFragment characterFragment =
authorAccess.getDocumentController().createNewDocumentTextFragment
(String.valueOf(ch));
      handleTyping = handleInsertionEvent
(offset, new AuthorDocumentFragment[] {characterFragment}, authorAccess);
    } catch (AuthorOperationException e) {
      throw new InvalidEditException
(e.getMessage(), "Invalid typing event: " + e.getMessage(), e, false);
    }
  }
  return handleTyping;
}
```

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Methods for Improving the Paste Mechanism

getAncestorDetectionOptions

When pasting content in **Author** mode, if the result causes the document to become invalid, Oxygen XML Editor will propose solutions to make it valid. As a possible solution, Oxygen XML Editor might surround the pasted content in a sequence of ancestor elements. This *getAncestorDetectionOptions* method allows you to choose which parent elements might be a possible solution.

canBeReplaced

Allows you to improve solutions that might be proposed by the paste mechanism when pasting content in Oxygen XML Editor. For example, when pasting an element inside an empty element with the same name, this *canBeReplaced* method allows Oxygen XML Editor to replace the empty node rather than pasting it after or before the empty node. The callback could also reject this behavior if, for instance, the replacement node contains attributes.

AuthorDocumentFragment Class

Implementing an Edit Properties Handler for Author Mode

The *EditPropertiesHandler* extension point allows you to present a specialized dialog box when the action of double-clicking an element tag is intercepted in **Author** mode. For example, you could use it to present a dialog box that allows the user to editing the properties of an image.

How to Implement an *EditPropertiesHandler*

To implement your own *EditPropertiesHandler*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.EditPropertiesHandler* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have *configured an extensions bundle*, you can return the *EditPropertiesHandler* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.createEditPropertiesHandler()* method.
   b. Specify the *EditPropertiesHandler* in the **Author edit properties handler** individual extension in the ***Extensions** tab* of the ***Document Type** configuration dialog box* for your particular document type.

Example

The following example illustrates an implementation for presenting a simple properties editing dialog box when a user double-clicks an `image` tag in **Author** mode (with tags displayed from the **Tags display mode** drop-down menu):

```
public class CustomEditPropertiesHandler implements EditPropertiesHandler {

  /**
   * @see ro.sync.ecss.extensions.api.Extension#getDescription()
   */
  @Override
  public String getDescription() {
    return "Sample implementation that handles properties for a table element.";
  }

  /**
   * @see ro.sync.ecss.extensions.api.EditPropertiesHandler#canEditProperties
(ro.sync.ecss.extensions.api.node.AuthorNode)
   */
  @Override
  public boolean canEditProperties(AuthorNode authorNode) {
    // If this node is an image element we can edit its properties.
    return "image".equals(authorNode.getDisplayName());
  }

  /**
   * @see ro.sync.ecss.extensions.api.EditPropertiesHandler#editProperties
(ro.sync.ecss.extensions.api.node.AuthorNode,
 ro.sync.ecss.extensions.api.AuthorAccess)
   */
  @Override
  public void editProperties(AuthorNode authorNode, AuthorAccess authorAccess) {
    // If we receive this call then it surely an image.
    AuthorElement imageElement = (AuthorElement) authorNode;
    String currentValue = "";
    AttrValue altValue = imageElement.getAttribute("alt");
```

```
    if (altValue != null) {
      currentValue = altValue.getValue();
    }
    String newValue = JOptionPane.showInputDialog(
        (Component) authorAccess.getWorkspaceAccess().getParentFrame(),
        "Alternate text",
        currentValue);

    if (newValue != null) {
      authorAccess.getDocumentController().setAttribute
("alt", new AttrValue(newValue), imageElement);
    }
  }
}
```

Example result: If a user were to double-click an `image` tag icon () in **Author** mode, the following dialog box would be displayed that allows the user to edit the *alternate text* property for the image:

Implementing a Custom Attribute Value Editor

The *CustomAttributeValueEditor* extension point allows you customize the attribute value editing mechanisms in Oxygen XML Editor. It changes the **Browse** button found in the attribute editors to an **Edit** button. When a user clicks that **Edit** button, your custom attribute value editor will be presented.

The **Edit** button can be accessed in the following attribute editors:

- The ***Attributes** view in **Author** mode* (when the **Expand** button is used to reveal an expanded panel).
- The ***Attributes** view in **Text** mode* (when the **Expand** button is used to reveal an expanded panel).
- The ***In-place Attributes Editor*** when invoked in **Author** mode.
- The ***In-place Attributes Editor*** invoked in the **Outline** view when editing in **Author** mode.
- The ***In-place Attributes Editor*** invoked in the **Outline** view when editing in **Text** mode.

How to Implement a *CustomAttributeValueEditor*

To implement your own *CustomAttributeValueEditor*, follow this procedure:

1. Extend the *ro.sync.ecss.extensions.api.CustomAttributeValueEditor* abstract class.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have *configured an extensions bundle*, you can return the *CustomAttributeValueEditor* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.createCustomAttributeValueEditor()* method.
   b. Specify the *CustomAttributeValueEditor* in the **Author custom attribute value editor** individual extension in the ***Extensions** tab* of the ***Document Type** configuration dialog box* for your particular document type.

Example

The following example creates a very simple custom attribute value editor:

```
/**
 * A custom attribute value editor.
 */
public class MyCustomAttributeValueEditor extends CustomAttributeValueEditor {

  /**
   * @see ro.sync.ecss.extensions.api.Extension#getDescription()
   */
  @Override
  public String getDescription() {
    return "My custom attribute value editor";
  }

  /**
```

```
   * @see ro.sync.ecss.extensions.api.CustomAttributeValueEditor#getAttributeValue
            (ro.sync.ecss.extensions.api.EditedAttribute, java.lang.Object)
   */
  @Override
  public String getAttributeValue(EditedAttribute attribute, Object parentComponent)
      throws CancelledByUserException {
    // Show an input dialog for collecting the new value
    return JOptionPane.showInputDialog
                    ("Set a new value for " + attribute.getAttributeQName() + ":");
  }

  /**
   * @see ro.sync.ecss.extensions.api.CustomAttributeValueEditor#shouldHandleAttribute
                   (ro.sync.ecss.extensions.api.EditedAttribute)
   */
  @Override
  public boolean shouldHandleAttribute(EditedAttribute attribute) {
    // Handle all attributes
    return true;
  }
}
```

Example result: If a user were to click the  **Edit** button in any of the attribute editors, the following dialog box would be displayed that allows the user to insert a value for the particular attribute:

Implementing an Author Mode Action Event Handler

The *AuthorActionEventHandler* extension point allows you to handle certain **Author** mode actions in a special way. For example, a specific use-case would be if you want to insert new lines when you press **Enter** instead of it opening the *Content Completion Assistant*.

How to Implement an *AuthorActionEventHandler*

To implement your own *AuthorActionEventHandler*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorActionEventHandler* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have *configured an extensions bundle*, you can return the *AuthorActionEventHandler* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorActionEventHandler()* method.
   b. Specify the *AuthorActionEventHandler* in the **Author action event handler** individual extension in the ***Extensions** tab* of the ***Document Type** configuration dialog box* for your particular document type.

Example

The following example illustrates the use-case mentioned in the introduction, that is an implementation for inserting a new line when the user presses **Enter** in **Author** mode. It uses the *canHandleEvent* method to make sure the insertion will be performed in an element that will preserve the `new-line` character. Then the *handleEvent* method inserts the new line at the current cursor position.

```
public class CustomAuthorActionEventHandler implements AuthorActionEventHandler
{

 /**
  * @see ro.sync.ecss.extensions.api.AuthorActionEventHandler#canHandleEvent
(AuthorAccess, AuthorActionEventType)
  */
  @Override
  public boolean canHandleEvent(AuthorAccess authorAccess,
AuthorActionEventType type) {
    boolean canHandle = false;

    if (type == AuthorActionEventType.ENTER) {
      AuthorDocumentController documentController =
authorAccess.getDocumentController();
    int caretOffset = authorAccess.getEditorAccess().getCaretOffset();
```

```
    try {
      AuthorNode nodeAtOffset = documentController.getNodeAtOffset(caretOffset);
      if (nodeAtOffset instanceof AuthorElement) {
        AuthorElement elementAtOffset = (AuthorElement) nodeAtOffset;
        AttrValue xmlSpace = elementAtOffset.getAttribute("xml:space");
        if (xmlSpace != null && xmlSpace.getValue().equals("preserve")) {
          canHandle = true;
        }
      }
    } catch (BadLocationException ex) {
        if (logger.isDebugEnabled()) {
          logger.error(ex.getMessage(), ex);
        }
      }
    }

    return canHandle;
  }

 /**
  * @see ro.sync.ecss.extensions.api.AuthorActionEventHandler#handleEvent
(ro.sync.ecss.extensions.api.AuthorAccess,
ro.sync.ecss.extensions.api.AuthorActionEventHandler.AuthorActionEventType)
  */
  @Override
  public boolean handleEvent(AuthorAccess authorAccess,
 AuthorActionEventType eventType) {
    int caretOffset = authorAccess.getEditorAccess().getCaretOffset();
    // Insert a new line
    authorAccess.getDocumentController().insertText(caretOffset, "\n");
    return true;
  }

  /**
   * @see ro.sync.ecss.extensions.api.Extension#getDescription()
   */
  @Override
  public String getDescription() {
    return "Insert a new line";
  }
}
```

Implementing an Image Decorator for Author Mode

The *AuthorImageDecorator* extension point allows you to add a custom decorator over images in **Author** mode. For example, you could use it to add a message over an image informing the user that they can double-click the image to edit it.

How to Implement an *AuthorImageDecorator*

To implement your own *AuthorImageDecorator*, follow this procedure:

1. Implement the *ro.sync.ecss.extensions.api.AuthorImageDecorator* interface.
2. To instruct Oxygen XML Editor to use this newly created implementation, use either of the following methods:
   a. If you have *configured an extensions bundle*, you can return the *AuthorImageDecorator* implementation using the *ro.sync.ecss.extensions.api.ExtensionsBundle.getAuthorImageDecorator()* method.
   b. Specify the *AuthorImageDecorator* in the **Author image decorator** individual extension in the ***Extensions** tab* of the ***Document Type** configuration dialog box* for your particular document type.

Example

The following example illustrates an implementation for presenting a simple message over an image that informs the user that they can double-click the image to edit it:

```
/**
 * Custom Author image decorator for drawing string over images.
 */
public class CustomAuthorImageDecorator extends AuthorImageDecorator {

  /**
   * @see ro.sync.ecss.extensions.api.AuthorImageDecorator#paint
(ro.sync.exml.view.graphics.Graphics, int, int, int, int,
 ro.sync.exml.view.graphics.Rectangle,
 ro.sync.ecss.extensions.api.node.AuthorNode,
 ro.sync.ecss.extensions.api.AuthorAccess, boolean)
   */
  @Override
  public void paint(Graphics g, int x, int y, int imageWidth, int imageHeight,
      Rectangle originalSize, AuthorNode element,
 AuthorAccess authorAccess, boolean wasAnnotated) {
    if ("image".equals(CommonsOperationsUtil.getLocalName(element.getName()))) {
      g.drawString(
```

```
          "[Double-click to edit image]",
          // Draw near the top-left corner
          x + 15,
          y + 15);
    }
  }
```

Example result: In the top-left corner of the image, the following message will be displayed: `[Double-click to edit image]`.

Implementing a State Listener for Author Mode

The *ro.sync.ecss.extensions.api.AuthorExtensionStateListener* implementation is notified when the **Author** mode extension (where the listener is defined) is activated or deactivated in the document type detection process.

```
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorExtensionStateListener;

public class SDFAuthorExtensionStateListener implements
  AuthorExtensionStateListener {
  private AuthorListener sdfAuthorDocumentListener;
  private AuthorMouseListener sdfMouseListener;
  private AuthorCaretListener sdfCaretListener;
  private OptionListener sdfOptionListener;
```

When the association rules of the *framework* (document type) configuration match that of a document opened in the **Author** editing mode, the *activation* event received by this listener should be used to perform custom initializations and to register listeners such as *ro.sync.ecss.extensions.api.AuthorListener*, *ro.sync.ecss.extensions.api.AuthorMouseListener*, or *ro.sync.ecss.extensions.api.AuthorCaretListener*.

```
 public void activated(AuthorAccess authorAccess) {
   // Get the value of the option.
   String option = authorAccess.getOptionsStorage().getOption(
               "sdf.custom.option.key", "");
   // Use the option for some initializations...

   // Add an OptionListener.
   authorAccess.getOptionsStorage().addOptionListener(sdfOptionListener);

   // Add author DocumentListeners.
   sdfAuthorDocumentListener = new SDFAuthorListener();
   authorAccess.getDocumentController().addAuthorListener(
               sdfAuthorDocumentListener);

   // Add MouseListener.
   sdfMouseListener = new SDFAuthorMouseListener();
   authorAccess.getEditorAccess().addAuthorMouseListener(sdfMouseListener);

   // Add CaretListener.
   sdfCaretListener = new SDFAuthorCaretListener();
   authorAccess.getEditorAccess().addAuthorCaretListener(sdfCaretListener);

   // Other custom initializations...

 }
```

The authorAccess parameter received by the *activated* method can be used to gain access to specific **Author** mode actions and informations related to components such as the editor, document, workspace, tables, or the *change tracking* manager.

If options specific to the custom developed *Author Extension* need to be stored or retrieved, a reference to the *ro.sync.ecss.extensions.api.OptionsStorage* can be obtained by calling the *getOptionsStorage* method from the authorAccess. The same object can be used to register *ro.sync.ecss.extensions.api.OptionListener* listeners. An option listener is registered in relation with an option **key** and will be notified about the value changes of that option.

An *AuthorListener* can be used if events related to the **Author** mode document modifications are of interest. The listener can be added to the *ro.sync.ecss.extensions.api.AuthorDocumentController*. A reference to the document controller is returned by the *getDocumentController* method from the authorAccess. The document controller can also be used to perform operations involving document modifications.

To provide access to the **Author** mode component-related functionality and information, the authorAccess has a reference to the *ro.sync.ecss.extensions.api.access.AuthorEditorAccess* that can be obtained when calling the *getEditorAccess* method. At this level, *AuthorMouseListener* and *AuthorCaretListener* can be added to provide notification of mouse and cursor events that occur in the **Author** editor mode.

The *deactivation* event is received when another *framework* is activated for the same document, the user switches to another editor mode or the editor is closed. The *deactivate* method is typically used to unregister the listeners previously added on the *activate* method and to perform other actions. For example, options related to the deactivated *Author Extension* can be saved at this point.

```
 public void deactivated(AuthorAccess authorAccess) {
   // Store the option.
   authorAccess.getOptionsStorage().setOption(
               "sdf.custom.option.key", optionValue);

   // Remove the OptionListener.
   authorAccess.getOptionsStorage().removeOptionListener(sdfOptionListener);

   // Remove DocumentListeners.
   authorAccess.getDocumentController().removeAuthorListener(
               sdfAuthorDocumentListener);

   // Remove MouseListener.
   authorAccess.getEditorAccess().removeAuthorMouseListener(sdfMouseListener);

   // Remove CaretListener.
   authorAccess.getEditorAccess().removeAuthorCaretListener(sdfCaretListener);

   // Other actions...

 }
```

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring a Content Completion Handler

You can filter or contribute to proposals offered for content completion by implementing the *ro.sync.contentcompletion.xml.SchemaManagerFilter* interface.

```
import java.util.List;

import ro.sync.contentcompletion.xml.CIAttribute;
import ro.sync.contentcompletion.xml.CIElement;
import ro.sync.contentcompletion.xml.CIValue;
import ro.sync.contentcompletion.xml.Context;
import ro.sync.contentcompletion.xml.SchemaManagerFilter;
import ro.sync.contentcompletion.xml.WhatAttributesCanGoHereContext;
import ro.sync.contentcompletion.xml.WhatElementsCanGoHereContext;
import ro.sync.contentcompletion.xml.WhatPossibleValuesHasAttributeContext;

public class SDFSchemaManagerFilter implements SchemaManagerFilter {
```

You can implement the various callbacks of the interface either by returning the default values given by Oxygen XML Editor or by contributing to the list of proposals. The filter can be applied on elements, attributes or on their values. Attributes filtering can be implemented using the *filterAttributes* method and changing the default content completion list of *ro.sync.contentcompletion.xml.CIAttribute* for the element provided by the current *ro.sync.contentcompletion.xml.WhatAttributesCanGoHereContext* context. For example, the `SDFSchemaManagerFilter` checks if the element from the current context is the `table` element and adds the `frame` attribute to the `table` list of attributes.

```
/**
 * Filter attributes of the "table" element.
 */
public List<CIAttribute> filterAttributes(List<CIAttribute> attributes,
    WhatAttributesCanGoHereContext context) {
  // If the element from the current context is the 'table' element add the
  // attribute named 'frame' to the list of default content completion proposals
  if (context != null) {
    ContextElement contextElement = context.getParentElement();
    if ("table".equals(contextElement.getQName())) {
      CIAttribute frameAttribute = new CIAttribute();
      frameAttribute.setName("frame");
      frameAttribute.setRequired(false);
      frameAttribute.setFixed(false);
      frameAttribute.setDefaultValue("void");
      if (attributes == null) {
        attributes = new ArrayList<CIAttribute>();
      }
      attributes.add(frameAttribute);
    }
  }
  return attributes;
}
```

The elements that can be inserted in a specific context can be filtered using the *filterElements* method. The SDFSchemaManagerFilter uses this method to replace the `td` child element with the `th` element when `header` is the current context element.

```
public List<CIElement> filterElements(List<CIElement> elements,
    WhatElementsCanGoHereContext context) {
  // If the element from the current context is the 'header' element remove the
  // 'td' element from the list of content completion proposals and add the
  // 'th' element.
  if (context != null) {
    Stack<ContextElement> elementStack = context.getElementStack();
    if (elementStack != null) {
      ContextElement contextElement = context.getElementStack().peek();
      if ("header".equals(contextElement.getQName())) {
        if (elements != null) {
          for (Iterator<CIElement> iterator =
elements.iterator(); iterator.hasNext();) {
            CIElement element = iterator.next();
            // Remove the 'td' element
            if ("td".equals(element.getQName())) {
              elements.remove(element);
              break;
            }
          }
        } else {
          elements = new ArrayList<CIElement>();
        }
        // Insert the 'th' element in the list of content completion proposals
        CIElement thElement = new SDFElement();
        thElement.setName("th");
        elements.add(thElement);
      }
    }
  } else {
    // If the given context is null then the given list of content completion
    // elements contains global elements.
  }
  return elements;
}
```

The elements or attributes values can be filtered using the *filterElementValues* or *filterAttributeValues* methods.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring a Link Target Element Finder

The link target reference finder represents the support for finding references from links that indicate specific elements inside an XML document. This support will only be available if a schema is associated with the document type.

If you do not define a custom link target reference finder, the *DefaultElementLocatorProvider* implementation will be used by default. The interface that should be implemented for a custom link target reference finder is *ro.sync.ecss.extensions.api.link.ElementLocatorProvider*. As an alternative, the *ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider* implementation can also be extended.

The used *ElementLocatorProvider* will be queried for an *ElementLocator* when a link location must be determined (when a link is clicked). Then, to find the corresponding (linked) element, the obtained *ElementLocator* will be queried for each element from the document.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

DefaultElementLocatorProvider Implementation

The *DefaultElementLocatorProvider* implementation offers support for the most common types of links:

- Links based on ID attribute values.
- XPointer element() scheme.

The method *getElementLocator* determines what *ElementLocator* should be used. In the default implementation, it checks if the link is an XPointer element() scheme. Otherwise, it assumes it is an ID. A non-null *IDTypeVerifier* will always be provided if a schema is associated with the document type.

The `link` string argument is the *anchor* part of the of the URL that is composed from the value of the link property specified for the link element in the CSS.

```
public ElementLocator getElementLocator(IDTypeVerifier idVerifier,
```

```
                String link) {
  ElementLocator elementLocator = null;
  try {
    if(link.startsWith("element(")){
      // xpointer element() scheme
      elementLocator = new XPointerElementLocator(idVerifier, link);
    } else {
      // Locate link element by ID
      elementLocator = new IDElementLocator(idVerifier, link);
    }
  } catch (ElementLocatorException e) {
    logger.warn("Exception when create element locator for link: "
        + link + ". Cause: " + e, e);
  }
  return elementLocator;
}
```

XPointerElementLocator Implementation

XPointerElementLocator is an implementation of the abstract class *ro.sync.ecss.extensions.api.link.ElementLocator* for links that have one of the following XPointer element() scheme patterns:

element (*elementID*)

Locate the element with the specified ID.

element (*/1/2/3*)

A child sequence appearing alone identifies an element by means of stepwise navigation, which is directed by a sequence of integers separated by slashes (/). Each integer n locates the nth child element of the previously located element.

element (*elementID/3/4*)

A child sequence appearing after a *NCName* identifies an element by means of stepwise navigation, starting from the element located by the given name.

The constructor separates the ID/integers, which are delimited by slashes(/) into a sequence of identifiers (an XPointer path). It will also check that the link has one of the supported patterns of the XPointer element() scheme.

```
public XPointerElementLocator(IDTypeVerifier idVerifier, String link)
                      throws ElementLocatorException {
  super(link);
  this.idVerifier = idVerifier;

  link = link.substring("element(".length(), link.length() - 1);

  StringTokenizer stringTokenizer = new StringTokenizer(link, "/", false);
  xpointerPath = new String[stringTokenizer.countTokens()];
  int i = 0;
  while (stringTokenizer.hasMoreTokens()) {
    xpointerPath[i] = stringTokenizer.nextToken();
    boolean invalidFormat = false;

    // Empty xpointer component is not supported
    if(xpointerPath[i].length() == 0){
      invalidFormat = true;
    }

    if(i > 0){
      try {
        Integer.parseInt(xpointerPath[i]);
      } catch (NumberFormatException e) {
        invalidFormat = true;
      }
    }

    if(invalidFormat){
      throw new ElementLocatorException(
        "Only the element() scheme is supported when locating XPointer links."
        + "Supported formats: element(elementID), element(/1/2/3),
              element(elemID/2/3/4).");
    }
    i++;
  }

  if(Character.isDigit(xpointerPath[0].charAt(0))){
    // This is the case when xpointer have the following pattern /1/5/7
    xpointerPathDepth = xpointerPath.length;
  } else {
    // This is the case when xpointer starts with an element ID
    xpointerPathDepth = -1;
    startWithElementID  = true;
```

```
  }
}
```

The method *startElement* will be invoked at the beginning of every element in the XML document(even when the element is empty). The arguments it takes are

uri

The namespace URI, or the empty string if the element has no namespace URI or if namespace processing is disabled.

localName

Local name of the element.

qName

Qualified name of the element.

atts

Attributes attached to the element. If there are no attributes, this argument will be empty.

The method returns `true` if the processed element is found to be the one indicated by the link.

The *XPointerElementLocator* implementation of the *startElement* will update the depth of the current element and keep the index of the element in its parent. If the `xpointerPath` starts with an element ID then the current element ID is verified to match the specified ID. If this is the case the depth of the XPointer is updated taking into account the depth of the current element.

If the XPointer path depth is the same as the current element depth then the kept indices of the current element path are compared to the indices in the XPointer path. If all of them match then the element has been found.

```
public boolean startElement(String uri, String localName,
        String name, Attr[] atts) {
  boolean linkLocated = false;
  // Increase current element document depth
  startElementDepth ++;

  if (endElementDepth != startElementDepth) {
    // The current element is the first child of the parent
    currentElementIndexStack.push(new Integer(1));
  } else {
    // Another element in the parent element
    currentElementIndexStack.push(new Integer(lastIndexInParent + 1));
  }

  if (startWithElementID) {
    // This the case when xpointer path starts with an element ID.
    String xpointerElement = xpointerPath[0];
    for (int i = 0; i < atts.length; i++) {
      if(xpointerElement.equals(atts[i].getValue())){
        if(idVerifier.hasIDType(
            localName, uri, atts[i].getQName(), atts[i].getNamespace())){
          xpointerPathDepth = startElementDepth + xpointerPath.length - 1;
          break;
        }
      }
    }
  }

  if (xpointerPathDepth == startElementDepth){
    // check if xpointer path matches with the current element path
    linkLocated = true;
    try {
      int xpointerIdx = xpointerPath.length - 1;
      int stackIdx = currentElementIndexStack.size() - 1;
      int stopIdx = startWithElementID ? 1 : 0;
      while (xpointerIdx >= stopIdx && stackIdx >= 0) {
        int xpointerIndex = Integer.parseInt(xpointerPath[xpointerIdx]);
        int currentElementIndex =
          ((Integer)currentElementIndexStack.get(stackIdx)).intValue();
        if(xpointerIndex != currentElementIndex) {
          linkLocated = false;
          break;
        }

        xpointerIdx--;
        stackIdx--;
      }

    } catch (NumberFormatException e) {
      logger.warn(e,e);
    }
  }
```

```
  return linkLocated;
}
```

The method *endElement* will be invoked at the end of every element in the XML document (even when the element is empty).

The *XPointerElementLocator* implementation of the *endElement* updates the depth of the current element path and the index of the element in its parent.

```
public void endElement(String uri, String localName, String name) {
  endElementDepth = startElementDepth;
  startElementDepth --;
  lastIndexInParent = ((Integer)currentElementIndexStack.pop()).intValue();
}
```

IDElementLocator Implementation

The *IDElementLocator* is an implementation of the abstract class *ro.sync.ecss.extensions.api.link.ElementLocator* for links that use an **ID**.

The constructor only assigns field values and the method *endElement* is empty for this implementation.

The method *startElement* checks each of the element's attribute values and when one matches the link, it considers the element found if one of the following conditions is satisfied:

- the qualified name of the attribute is `xml:id`
- the attribute type is ID

The attribute type is checked with the help of the method *IDTypeVerifier.hasIDType*.

```
public boolean startElement(String uri, String localName,
        String name, Attr[] atts) {
  boolean elementFound = false;
  for (int i = 0; i < atts.length; i++) {
    if (link.equals(atts[i].getValue())) {
      if("xml:id".equals(atts[i].getQName())) {
        // xml:id attribute
        elementFound = true;
      } else {
        // check if attribute has ID type
        String attrLocalName =
          ExtensionUtil.getLocalName(atts[i].getQName());
        String attrUri = atts[i].getNamespace();
        if (idVerifier.hasIDType(localName, uri, attrLocalName, attrUri)) {
          elementFound = true;
        }
      }
    }
  }

  return elementFound;
}
```

Creating a Customized Link Target Reference Finder

If you need to create a custom link target reference finder you can do so by creating the class that will implement the *ro.sync.ecss.extensions.api.link.ElementLocatorProvider* interface. As an alternative, your class could extend *ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider*, the default implementation.

Note: The complete source code of the *ro.sync.ecss.extensions.commons.DefaultElementLocatorProvider*, *ro.sync.ecss.extensions.commons.IDElementLocator* or *ro.sync.ecss.extensions.commons.XPointerElementLocator* can be found in the **oxygen-sample-framework** project.

Configuring a Custom Drag and Drop Listener

Sometimes it is useful to perform various operations when certain objects are dropped from outside sources in the editing area. You can choose from three interfaces to implement depending on whether you are using the Eclipse plugin or the standalone version of the application or if you want to add the handler for the **Text** or **Author** modes.

Interfaces for the Drag and Drop Listener

ro.sync.exml.editor.xmleditor.pageauthor.AuthorDnDListener

Receives callbacks from the standalone application for Drag And Drop in **Author** mode.

com.oxygenxml.editor.editors.author.AuthorDnDListener

Receives callbacks from the Eclipse plugin for Drag And Drop in **Author** mode.

com.oxygenxml.editor.editors.TextDnDListener

Receives callbacks from the Eclipse plugin for Drag And Drop in **Text** mode.

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring a References Resolver

This information is helpful if you need to provide a handler for resolving references and obtain the content they reference. For example, suppose the element that has references is **ref** and the attribute indicating the referenced resource is **location**. You need to implement a Java extension class for obtaining the referenced resources.

1. Create the class *simple.documentation.framework.ReferencesResolver*. This class must implement the *ro.sync.ecss.extensions.api.AuthorReferenceResolver* interface.

```
import ro.sync.ecss.extensions.api.AuthorReferenceResolver;
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.node.AttrValue;
import ro.sync.ecss.extensions.api.node.AuthorElement;
import ro.sync.ecss.extensions.api.node.AuthorNode;

public class ReferencesResolver
      implements AuthorReferenceResolver {
```

2. The *hasReferences* method verifies if the handler considers the node to have references. It takes *AuthorNode* as an argument that represents the node that will be verified. The method will return `true` if the node is considered to have references. For our example, to be a reference, the node must be an element with the name *ref* and it must have an attribute named *location*.

```
public boolean hasReferences(AuthorNode node) {
  boolean hasReferences = false;
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      hasReferences = attrValue != null;
    }
  }
  return hasReferences;
}
```

3. The method *getDisplayName* returns the display name of the node that contains the expanded referenced content. It takes *AuthorNode* as an argument that represents the node for which the display name is needed. The referenced content engine will ask this *AuthorReferenceResolver* implementation for the display name for each node that is considered a reference. For our example, the display name is the value of the *location* attribute from the *ref* element.

```
public String getDisplayName(AuthorNode node) {
  String displayName = "ref-fragment";
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        displayName = attrValue.getValue();
      }
    }
  }
  return displayName;
}
```

4. The method *resolveReference* resolves the reference of the node and returns a *SAXSource* with the parser and its input source. It takes *AuthorNode* as an argument that represents the node for which the reference needs resolving, the `systemID` of the node, the *AuthorAccess* with access methods to the **Author** mode data model and a SAX *EntityResolver* that resolves resources that are already opened in another editor or resolve resources through the *XML Catalog*. In the implementation, you need to resolve the reference relative to the `systemID`, and create a parser and an input source over the resolved reference.

```
public SAXSource resolveReference(
    AuthorNode node,
    String systemID,
    AuthorAccess authorAccess,
    EntityResolver  entityResolver) {
```

```
  SAXSource saxSource = null;

  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        String attrStringVal = attrValue.getValue();
        try {
          URL absoluteUrl = new URL(new URL(systemID),
          authorAccess.getUtilAccess().correctURL(attrStringVal));

          InputSource inputSource = entityResolver.resolveEntity(null,
              absoluteUrl.toString());
          if(inputSource == null) {
            inputSource = new InputSource(absoluteUrl.toString());
          }

          XMLReader xmlReader = authorAccess.newNonValidatingXMLReader();
          xmlReader.setEntityResolver(entityResolver);

          saxSource = new SAXSource(xmlReader, inputSource);
        } catch (MalformedURLException e) {
          logger.error(e, e);
        } catch (SAXException e) {
          logger.error(e, e);
        } catch (IOException e) {
          logger.error(e, e);
        }
      }
    }
  }

  return saxSource;
}
```

5. The method *getReferenceUniqueID* should return a unique identifier for the node reference. The unique identifier is used to avoid resolving the references recursively. The method takes *AuthorNode* as an argument that represents the node with the reference. In our example, the unique identifier is the value of the *location* attribute from the *ref* element.

```
public String getReferenceUniqueID(AuthorNode node) {
  String id = null;
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        id = attrValue.getValue();
      }
    }
  }
  return id;
}
```

6. The method *getReferenceSystemID*should return the `systemID` of the referenced content. It takes *AuthorNode* as an argument that represents the node with the reference and the *AuthorAccess* with access methods to the **Author** mode data model. In our example, the value of the *location* attribute is used from the *ref* element and resolved relatively to the XML base URL of the node.

```
public String getReferenceSystemID(AuthorNode node,
                                   AuthorAccess authorAccess) {
  String systemID = null;
  if (node.getType() == AuthorNode.NODE_TYPE_ELEMENT) {
    AuthorElement element = (AuthorElement) node;
    if ("ref".equals(element.getLocalName())) {
      AttrValue attrValue = element.getAttribute("location");
      if (attrValue != null) {
        String attrStringVal = attrValue.getValue();
        try {
          URL absoluteUrl = new URL(node.getXMLBaseURL(),
              authorAccess.getUtilAccess().correctURL(attrStringVal));
          systemID = absoluteUrl.toString();
        } catch (MalformedURLException e) {
          logger.error(e, e);
        }
      }
    }
  }
  return systemID;
}
```

In the listing below, the XML document contains the **ref** element:

```
<ref location="referenced.xml">Reference</ref>
```

When no reference resolver is specified, the reference has the following layout:

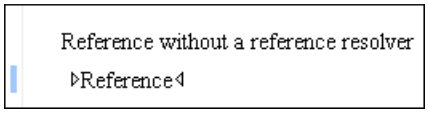

Figure 721: Reference with no specified reference resolver

When the above implementation is configured, the reference has the expected layout:

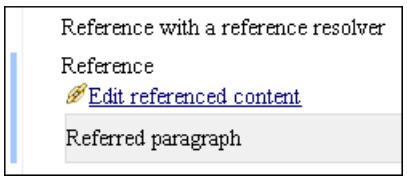

Figure 722: Reference with reference resolver

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring CSS Styles Filter

You can modify the CSS styles for each *ro.sync.ecss.extensions.api.node.AuthorNode* rendered in the **Author** mode using an implementation of *ro.sync.ecss.extensions.api.StylesFilter*. You can implement the various callbacks of the interface either by returning the default value given by Oxygen XML Editor or by contributing to the value. The received styles *ro.sync.ecss.css.Styles* can be processed and values can be overwritten with your own. For example, you can override the KEY_BACKGROUND_COLOR style to return your own implementation of *ro.sync.exml.view.graphics.Color* or override the KEY_FONT style to return your own implementation of *ro.sync.exml.view.graphics.Font*.

For instance, in our simple document example the filter can change the value of the KEY_FONT property for the `table` element:

```
package simple.documentation.framework;

import ro.sync.ecss.css.Styles;
import ro.sync.ecss.extensions.api.StylesFilter;
import ro.sync.ecss.extensions.api.node.AuthorNode;
import ro.sync.exml.view.graphics.Font;

public class SDFStylesFilter implements StylesFilter {

     public Styles filter(Styles styles, AuthorNode authorNode) {
         if (AuthorNode.NODE_TYPE_ELEMENT == authorNode.getType()
           && "table".equals(authorNode.getName())) {
           styles.setProperty(Styles.KEY_FONT, new Font(null, Font.BOLD, 12));
         }
         return styles;
     }
}
```

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring Tables

There are standard CSS properties used to indicate what elements are tables, table rows and table cells. What CSS is missing is the possibility to indicate the cell spanning, row separators or the column widths. Oxygen XML Editor offers support for adding extensions to solve these problems.

The table in this example is a simple one. The header must be formatted in a different way than the ordinary rows, so it will have a background color.

```
table{
    display:table;
    border:1px solid navy;
    margin:1em;
    max-width:1000px;
    min-width:150px;
}
```

```
table[width]{
  width:attr(width, length);
}

tr, header{
    display:table-row;
}

header{
    background-color: silver;
    color:inherit
}

td{
  display:table-cell;
  border:1px solid navy;
  padding:1em;
}
```

Since in the *schema*, the `td` tag has the attributes **row_span** and **column_span** that are not automatically recognized by Oxygen XML Editor, a Java extension will be implemented that will provide information about the cell spanning. See the section *Configuring a Table Cell Span Provider*.

The column widths are specified by the attributes **width** of the elements `customcol` that are not automatically recognized by Oxygen XML Editor. It is necessary to implement a Java extension that will provide information about the column widths. For more information, see *Configuring a Table Column Width Provider*.

The table from our example does not make use of the attributes `colsep` and `rowsep` (which are automatically recognized) but we still want the rows to be separated by horizontal lines. It is necessary to implement a Java extension that will provide information about the row and column separators. For more information, see *Configuring a Table Cell Row and Column Separator Provider* on page 1451.

Configuring a Table Column Width Provider

In a custom *framework*, the `table` element as well as the table columns can have specified widths. For these widths to be considered by **Author** mode we need to provide the means to determine them. As explained in *Configuring Tables* on page 1445, if you use the table element attribute **width** Oxygen XML Editor can determine the table width automatically. In this example the table has `col` elements with **width** attributes that are not recognized by default. You will need to implement a Java extension class to determine the column widths.

1. Create the class *simple.documentation.framework.TableColumnWidthProvider*. This class must implement the *ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider* interface.

```
import ro.sync.ecss.extensions.api.AuthorAccess;
import ro.sync.ecss.extensions.api.AuthorOperationException;
import ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider;
import ro.sync.ecss.extensions.api.WidthRepresentation;
import ro.sync.ecss.extensions.api.node.AuthorElement;

public class TableColumnWidthProvider
      implements AuthorTableColumnWidthProvider {
```

2. Method *init* is taking as argument an *ro.sync.ecss.extensions.api.node.AuthorElement* that represents the XML `table` element. In our case the column widths are specified in `col` elements from the `table` element. In such cases you must collect the span information by analyzing the `table` element.

```
public void init(AuthorElement tableElement) {
 this.tableElement = tableElement;
 AuthorElement[] colChildren = tableElement.getElementsByLocalName("customcol");
    if (colChildren != null && colChildren.length > 0) {
 for (int i = 0; i < colChildren.length; i++) {
   AuthorElement colChild = colChildren[i];
     if (i == 0) {
  colsStartOffset = colChild.getStartOffset();
 }
     if (i == colChildren.length - 1) {
  colsEndOffset = colChild.getEndOffset();
 }
     // Determine the 'width' for this col.
     AttrValue colWidthAttribute = colChild.getAttribute("width");
     String colWidth = null;
     if (colWidthAttribute != null) {
       colWidth = colWidthAttribute.getValue();
           // Add WidthRepresentation objects for the columns this 'customcol'
     //  specification spans over.
  colWidthSpecs.add(new WidthRepresentation(colWidth, true));
 }
     }
   }
}
```

3. The method *isTableAcceptingWidth* should check if the table cells are `td`.

```
public boolean isTableAcceptingWidth(String tableCellsTagName) {
  return "td".equals(tableCellsTagName);
}
```

4. The method *isTableAndColumnsResizable* should check if the table cells are `td`. This method determines if the table and its columns can be resized by dragging the edge of a column.

```
public boolean isTableAndColumnsResizable(String tableCellsTagName) {
  return "td".equals(tableCellsTagName);
}
```

5. Methods *getTableWidth* and *getCellWidth* are used to determine the table and column width. The table layout engine will ask this *ro.sync.ecss.extensions.api.AuthorTableColumnWidthProvider* implementation what is the table width for each table element and the cell width for each cell element from the table that was marked as cell in the CSS using the property `display:table-cell`. The implementation is simple and just parses the value of the **width** attribute. The methods must return `null` for the tables / cells that do not have a specified width.

```
 public WidthRepresentation getTableWidth(String tableCellsTagName) {
  WidthRepresentation toReturn = null;
  if (tableElement != null && "td".equals(tableCellsTagName)) {
   AttrValue widthAttr = tableElement.getAttribute("width");
   if (widthAttr != null) {
    String width = widthAttr.getValue();
    if (width != null) {
     toReturn = new WidthRepresentation(width, true);
    }
   }
  }
  return toReturn;
 }
```

```
       public List<WidthRepresentation>
getCellWidth(AuthorElement cellElement, int colNumberStart,
   int colSpan) {
  List<WidthRepresentation> toReturn = null;
  int size = colWidthSpecs.size();
  if (size >= colNumberStart && size >= colNumberStart + colSpan) {
   toReturn = new ArrayList<WidthRepresentation>(colSpan);
   for (int i = colNumberStart; i < colNumberStart + colSpan; i ++) {
    // Add the column widths
    toReturn.add(colWidthSpecs.get(i));
   }
  }
  return toReturn;
 }
```

6. Methods *commitTableWidthModification* and *commitColumnWidthModifications* are used to commit changes made to the width of the table or its columns when using the mouse drag gestures.

```
 public void commitTableWidthModification
(AuthorDocumentController authorDocumentController,
 int newTableWidth, String tableCellsTagName) throws AuthorOperationException {
 if ("td".equals(tableCellsTagName)) {
  if (newTableWidth > 0) {
   if (tableElement != null) {
    String newWidth = String.valueOf(newTableWidth);

    authorDocumentController.setAttribute(
      "width",
      new AttrValue(newWidth),
      tableElement);
   } else {
 throw new AuthorOperationException("Cannot find the table element.");
    }
   }
  }
 }
```

```
public void commitColumnWidthModifications
 (AuthorDocumentController authorDocumentController,
   WidthRepresentation[] colWidths, String tableCellsTagName)
 throws AuthorOperationException {
   if ("td".equals(tableCellsTagName)) {
     if (colWidths != null && tableElement != null) {
 if (colsStartOffset >= 0 && colsEndOffset >= 0
&& colsStartOffset < colsEndOffset) {
  authorDocumentController.delete(colsStartOffset,
    colsEndOffset);
  }
  String xmlFragment = createXMLFragment(colWidths);
```

```
    int offset = -1;
   AuthorElement[] header = tableElement.getElementsByLocalName("header");
    if (header != null && header.length > 0) {
     // Insert the cols elements before the 'header' element
     offset = header[0].getStartOffset();
    }
    if (offset == -1) {
   throw new AuthorOperationException("No valid offset to insert column width");
     }
     authorDocumentController.insertXMLFragment(xmlFragment, offset);
    }
   }
  }

  private String createXMLFragment(WidthRepresentation[] widthRepresentations) {
   StringBuffer fragment = new StringBuffer();
   String ns = tableElement.getNamespace();
   for (int i = 0; i < widthRepresentations.length; i++) {
    WidthRepresentation width = widthRepresentations[i];
    fragment.append("<customcol");
    String strRepresentation = width.getWidthRepresentation();
    if (strRepresentation != null) {
     fragment.append(" width=\"" + width.getWidthRepresentation() + "\"");
    }
    if (ns != null && ns.length() > 0) {
     fragment.append(" xmlns=\"" + ns + "\"");
    }
    fragment.append("/>");
   }
   return fragment.toString();
  }
```

7. The following three methods are used to determine what type of column width specifications the table column width provider support. In our case all types of specifications are allowed:

```
  public boolean isAcceptingFixedColumnWidths(String tableCellsTagName) {
   return true;
  }

  public boolean isAcceptingPercentageColumnWidths(String tableCellsTagName) {
   return true;
  }

  public boolean isAcceptingProportionalColumnWidths(String tableCellsTagName) {
   return true;
  }
```

   Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

In the listing below, the XML document contains the table element:

```
<table width="300">
    <customcol width="50.0px"/>
    <customcol width="1*"/>
    <customcol width="2*"/>
    <customcol width="20%"/>
    <header>
        <td>C1</td>
        <td>C2</td>
        <td>C3</td>
        <td>C4</td>
    </header>
    <tr>
        <td>cs=1, rs=1</td>
        <td>cs=1, rs=1</td>
        <td row_span="2">cs=1, rs=2</td>
        <td row_span="3">cs=1, rs=3</td>
    </tr>
    <tr>
        <td>cs=1, rs=1</td>
        <td>cs=1, rs=1</td>
    </tr>
    <tr>
        <td column_span="3">cs=3, rs=1</td>
    </tr>
</table>
```

When no table column width provider is specified, the table has the following layout:

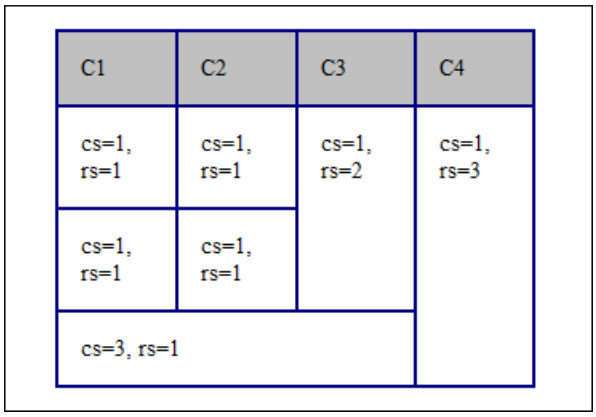

Figure 723: Table layout when no column width provider is specified

When the above implementation is configured, the table has the correct layout:

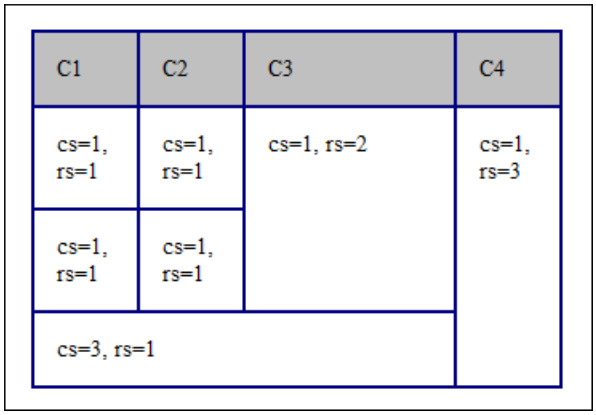

Figure 724: Columns with custom widths

Note: The complete source code for *framework* customization examples can be found in the **oxygen-sample-framework** module of the *Oxygen SDK* , available as a Maven archetype *on the Oxygen XML Editor website*.

Configuring a Table Cell Span Provider

In a custom *framework*, the `table` element can have cells that span over multiple columns and rows. As explained in *Configuring Tables* on page 1445, you need to indicate Oxygen XML Editor a method to determine the cell spanning. If you use the cell element attributes `rowspan` and `colspan` or `rows` and `cols`, Oxygen XML Editor can determine the cell spanning automatically. In our example the `td` element uses the attributes `row_span` and `column_span` that are not recognized by default. You will need to implement a Java extension class for defining the cell spanning.

1. Create the class *simple.documentation.framework.TableCellSpanProvider*. This class must implement the *ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider* interface.

```
import ro.sync.ecss.extensions.api.AuthorTableCellSpanProvider;
import ro.sync.ecss.extensions.api.node.AttrValue;
import ro.sync.ecss.extensions.api.node.AuthorElement;

public class TableCellSpanProvider
      implements AuthorTableCellSpanProvider {
```

2. The *init* method is taking as argument the *ro.sync.ecss.extensions.api.node.AuthorElement* that represents the XML `table` element. In our case the cell span is specified for each of the cells so you leave this method empty. However, there are cases (such as the CALS table model) when the cell spanning is specified in the `table` element. In such cases, you must collect the span information by analyzing the `table` element.

```
public void init(AuthorElement table) {
}
```

3. The *getColSpan* method is taking as argument the table cell. The table layout engine will ask this *AuthorTableSpanSupport* implementation what is the column span and the row span for each XML

element from the table that was marked as cell in the CSS using the property `display:table-cell`. The implementation is simple and just parses the value of **column_span** attribute. The method must return `null` for all the cells that do not change the span specification.

```
